**SUFFOLK** [sʌ′fək], a county on the east coast of England, bounded on the north by Norfolk, on the west by Cambridgeshire, on the south by Essex, and on the east by the North Sea. It covers an area of 1,482 sq. mi. of flat terrain, most of it less than 100 ft. above sea level, and is drained by the rivers Stour, Orwell, Waveney, Deben, and Alde. The county is composed of the two districts of East and West Suffolk, which, together with Norfolk, constitute East Anglia. Ipswich is the county town of East Suffolk, and Bury St. Edmunds is the shire town of West Suffolk.

Originally part of the kingdom of Iceni, Suffolk was ravaged by the Romans. Near the village of Mildenhall, Roman ornamental silver, a treasure of incalculable worth, was unearthed in 1946. The remains of Anglo-Saxon settlements are still to be seen. In the fifth century, Suffolk was the center of the kingdom of the Angles, and its medieval history is attested by the Norman churches at Walton and Walsoken. After the Conquest, Suffolk became a separate shire, and during the civil wars Mary Tudor raised an army there. For several centuries, Suffolk was among the most populous English counties, the cloth industry then providing a prosperous livelihood. Today the principal occupations are the raising of cereal crops, dairying, breeding the famous "Suffolk punch" draft horses, and fishing. Suffolk returns four members to Parliament. Pop. 1952, 453,500. B. Su.

**SUFFOLK,** a city in southeastern Virginia, county seat but independent of Nansemond Co., on the Nansemond River.

Peanuts, corn, and cotton are the leading crops of the region. The city is said to be the largest peanut market in the world. Founded about 1740, Suffolk was incorporated as a town in 1808 and as a city in 1910, and has the council-manager type of government. During the Civil War, Suffolk was in the hands of the Union troops. Transportation is afforded by the Seaboard Air Line, the Atlantic Coast Line, the Norfolk and Western, the Virginian, and the Atlantic and Danville railroads. Industries manufacture peanut products, cotton, lumber products, bricks, hosiery, fertilizer, overalls, confectionery, and packed meat. Pop. 1950, 12,339.

**SUFFRAGAN** [sʌ′frəgən], a title used of a diocesan bishop in relation to his archbishop, and of an assistant bishop, with limited powers, to a diocesan bishop. In the Anglican Church a suffragan bishop in the latter sense is distinguished from a bishop coadjutor in that the latter has the right of succession, when the diocesan dies or resigns, while a suffragan bishop does not possess this right. In the Church of England, a suffragan bishop may also hold a pastoral cure in the diocese to which he is appointed, but in the American Episcopal Church this is not allowed.

L. C. L.

**SUFFRAGE,** the right or privilege of voting. Suffrage is theoretically and historically associated with democratic political processes, especially as they are practiced in a system of representative government.

Two underlying theories of the franchise can be distinguished. (1) The vote is an inalienable right inhering from the rationality and moral perfectability of man. Originating in the popular sovereignty and natural rights theory of the eighteenth century, this concept of the franchise has been generally discredited. It has, nevertheless, furnished the ideological impetus for extending the franchise to an ever-widening electorate. (2) The vote is a political privilege, a function of government, conferred upon the individual by law and subject to qualifications which the governing authority may deem appropriate. This theory predominates in modern electoral systems, and the history of the franchise has been less a matter of questioning privilege as the basis for the vote than of liberalizing the disfranchising qualifications.

In the ancient world of Greece and Rome voting was an integral function of citizenship. All adult male citizens were equally entitled to the vote by reason of their citizenship. This practice prevailed among the Germanic folk tribes of the early Middle Ages and was briefly resurrected in the city states of the Italian Renaissance. With the rise of feudalism and a highly stratified social structure the vote became a prerogative of privileged status, a vested interest arising from membership in an estate and based principally upon ownership of land. Property ownership as a qualification for suffrage survived well into modern times and was expressed in weighted, or plural, voting. It characterized the electoral systems of imperial Russia and Germany, was finally abolished in Great Britain only in 1918, and still exists in Bolivia and Ceylon.

The growth of political democracy in the nineteenth and twentieth centuries resulted in an expanding franchise. Barriers of religion, property, race, and sex were steadily reduced, and there was a general movement toward universal adult suffrage. In Great Britain, the reforms of 1832, 1867, and 1884 gradually extended the suffrage to all adult males. Patriotic service during World War I and years of organized agitation were rewarded in 1918 when women over thirty received the franchise. Women were accorded equal suffrage rights in 1928 when the voting age was lowered to 21. In 1928, 60 per cent of the British population was entitled to vote, as compared with 4 per cent in 1831.

Voting in the United States is subject to state, not Federal, regulation. Except as limited by Constitutional amendment, each state is free to determine the electoral qualifications of its population. By the middle of the nineteenth century the enfranchisement of all adult white males was substantially achieved as property and religious limitations were rescinded. The Fifteenth Amendment (1870), which invalidated all abridgements due to "race, color, or previous condition of servitude," extended the suffrage to the Negro. The Nineteenth Amendment (1920) prohibited denial of suffrage because of sex.

Some indication of the progress made toward universal suffrage in recent times may be garnered from the following facts. Before World War I only a handful of countries (Scandinavia, New Zealand, and Australia) permitted women to vote. By 1928 only Spain, Italy, France, China, and Japan, among the great powers, withheld the ballot from women. After World War II new constitutions in France (1946), Italy (1947), China (1947), and Japan (1946) provided for woman suffrage. A few countries in Latin America (Mexico and Colombia) and the Near East (Egypt and Syria) and Switzerland still resist the trend and grant suffrage solely to males.

The expansion of communism has not proved incompatible with the movement toward a broadening electorate. Despite their dictatorial basis, Communist regimes utilize representative forms of government. The constitutions of the Soviet Union and the Communist states of Eastern Europe provide for universal and equal suffrage.

Requirements of citizenship, age, residence, and registration are limitations of the franchise which are almost universally observed. All nations require citizenship of their electorates, although the Soviet Union for a time permitted foreigners to vote in its elections. Residence and registration regulations are considered necessary to counteract fraudulence. Most countries have established twenty-one as the legal voting age, although in others the age varies from eighteen (in many countries) to twenty-five (Denmark). Traitors, certain kinds of criminals, and the mentally unsound are generally debarred, and in many countries bankrupts and members of the clergy, police, and armed forces are similarly denied the ballot. Literacy tests (in the Philippine Islands, Turkey, Chile, and eighteen states in the United States) and poll taxes (in seven states in the United States) are additional methods for measuring the acceptability of voters.

The development of modern transportation, the expansion of business across state and national frontiers, and the itinerancy of college students have emphasized the need for some form of absentee voting lest large numbers of qualified voters be disfranchised solely by virtue of absence from their locality. This problem was highlighted during World War II when millions of eligible voters were in the armed services. Many countries have tailored their electoral regulations to permit absentee voters to cast ballots. All but five states in the United States have absentee voting provisions, and three of the five permit absent servicemen to vote.

One of the most vexing problems of the suffrage is the extent to which eligible voters stay away from the polls on election day. In the United States only 50 to 70 per cent, on the average, of the electorate exercises its voting rights. In other democratic states the vote rarely exceeds 80 per cent and frequently dips as low as 60 per cent. Totalitarian states

regularly have turnouts only fractionally removed from 100 per cent, but it is reasonable to assume that compulsion, direct or indirect, is primarily responsible for the high vote. Some states (Belgium, Bolivia, and Uruguay) have tried to remedy this malaise by enacting legislation that makes voting obligatory and penalizes the nonvoter. Belgium has had a compulsory voting law since 1893, and as a result voting delinquency has been low, averaging between 5 and 10 per cent. Yet it is questionable whether compulsory voting attacks the evil of apathy and ignorance at the source. The need is not merely for a larger but, more important, for a better informed and more intelligent electorate. The solution seems to lie rather in a more vigorous program of civic education. C. Ro.

**SUFISM** [su'fɪzəm], the general name for Islamic mysticism. The term first appeared in Arabic writings in the middle of the ninth century of the Christian Era and was applied to a class of ascetics. The name Sufism is derived from Arabic *"sūf"* ("wool"), referring to the ascetic practice of wearing wool.

Sufism's beginnings, which are very obscure, took place during the eighth century. Sufism was, indeed, more of an emotional pattern than it was a set of disciplines and doctrines. It has often been described as a rebellion against Islam's intellectualism and the formalism that grew from the Koranic emphasis on the power and arbitrary sovereignty of Allah, but the early Sufis found support for their views in the Koran, quoting the passages: ". . . rely upon God, for God is guardian enough (33:47) . . . Be ye glad then in the covenant which ye have made with Him, for that is the mighty happiness. Those who repent, those who worship, those who praise, those who fear, those who bow down, those who adore . . . glad tidings to those who believe" (9:113-114).

Sufism is a response to the deep human aspiration for a personal relation with God and an immediate awareness of truth. Its purpose was to gain insight into the Divine Being, and the Sufi mystics maintained vigils, practiced contemplation, and experienced ecstasies.

Sufism gradually acquired large-scale significance; the symbols, orders, and cults, particularly in Persia, were popularized by the poets; and eventually Sufism became the central core of religious thought in the Moslem world. There was initiated through Sufism in the twelfth century a vast reorganization of the life of Islam, corresponding to the monastic orders of medieval Christendom.

As it grew, Sufism became a syncretic movement. The practice of wearing wool was copied from Christian monks, as were the customs of celibacy and nocturnal meditation; the Christian pattern of clergy-neophyte is evident in the *shaykh-murid* relationship; church litanies became a pattern for Islam's very elaborate ritual; the *tarīqat* (path) corresponds to the fraternity or order; and converts from Judaism and Christianity introduced such motifs as the antichrist.

Greek influence appeared in the belief, adopted by Islam, that ecstacy is a means for the attainment of divine knowledge. There are Hellenistic influences in Sufi theosophy, and the later schools show pantheistic traits derived from Buddhism and from Vedantic sources. For all its borrowings from other religions, however, it is noteworthy that Sufi mysticism takes its chief characteristics from Islam.

Sind is the home of Indian Sufism. The Moslems of Pakistan take kindly to the mystic cult, three fourths of them belonging to one of the four leading orders: the Chishtiyah and Suhrawardiyah, the Qadiriyah and Naqshabandiyah. Though generally quiescent in many a Moslem country, Sufism is by no means extinct in the modern world of Islam. E. J. J.

**SUFU.** *See* KASHGAR (SUFU).

**SUGAR AND CONFECTIONERY INDUSTRIES.** *See* FOOD INDUSTRIES.

**SUGAR BEET,** a biennial plant of the goosefoot family, grown as a source of sugar and for stock food. It may have been developed from the garden beet, *Beta vulgaris,* though not all botanists hold this opinion. The roots resemble those of the intermediate varieties of garden beet, but are white or yellowish, and somewhat larger. During the last century the sugar content of the sugar beet has, by breeding and selection, been increased from 7 per cent to as high as 24 per cent for the individual roots. Average yields are about 12 tons of beets, containing 2 tons of sugar, to the acre, though these are often exceeded to 10 or 20 per cent. Sugar yields of the roots have increased at the same time that the weight of roots necessary to produce a pound of sugar has been cut in half. These factors have made the crop profitable in both Europe and America, although land on the Continent is expensive, and the cost of labor in the United States is high. Sugar beets thrive best in cool climates and in well-drained, deep, rich loams. These are found in central Europe and northern and western United States and adjacent Canada. Sugar beet factories are expensive to erect and operate, hence suitable soils and near-by supplies of labor have been considerations in establishing such industries; the organizations usually maintain a staff of specialists to teach the growers how to produce good crops. V. A. T.

**SUGAR CANE,** a member of the grass family, *Saccharum officinarum.* Sugar cane is a coarse perennial and, because it yields cane sugar, one of the most important plants in the world. It is presumed to be a native of Asia or the East Indies, but, since the parent wild species has never been discovered, sugar cane is probably a cultigen. The Greeks and Romans had a somewhat vague knowledge of a reed from which the Hindus obtained sugar, for such a plant is mentioned in the writings of Strabo (c. 60 B.C.), Dioscorides (first century A.D.) and Pliny (A.D. 23). During the Middle Ages, sugar cane was brought by the Arabs into Egypt, Sicily, and Spain, where its cultivation flourished and remained important until large sugar plantations were developed in the American colonies. Sugar cane was introduced into Brazil about 1500, and soon afterwards to Mexico. It is now cultivated in most warm regions, especially in the East and West Indies, Brazil, Hawaii, and parts of Africa.

COURTESY OF BELGIAN GOVERNMENT INFORMATION CENTER

*Hoisting sugar cane at a sugar refinery in the Belgian Congo*

The plant has solid jointed canes, bears long stiff leaves, and has a large terminal flowering panicle. It flowers freely, but rarely sets seed in the tropics. It does not bloom in the United States. For commercial production, sugar cane is propagated by stem cuttings.

In the United States, sugar cane is grown from Texas to South Carolina, but in most of the states it is used for syrup only. Sugar is refined from it in Louisiana and Florida. Louisiana's cool weather makes it necessary to harvest the cane in an immature condition. The juice is therefore impure, containing a high amount of reducing sugar, and it is relatively low in sucrose. *See also* GRASSES; SORGHUM. C. K. H.

**SUGAR CHEMISTRY.** Sugars are a group of chemical compounds characterized by the following similarities: they are usually white, crystalline, are soluble in water, slightly soluble in alcohol, and insoluble in organic solvents. Most have varying degrees of sweetness. They have, with few exceptions, the empirical formula $C_m(H_2O)_n$, hence the generic name hydrate of carbon, or carbohydrate. Starch, dextrin, and cellulose are also carbohydrates. The sugars have one or more asymmetric carbon atoms; this structure gives them the property of rotating polarized light, or optical activity, a property used extensively in the analysis and characterization of sugars.

It is convenient to classify the sugars into two groups, with their subdivisions, as follows:

1. Monosaccharides
   - (*a*) Aldoses
   - (*b*) Ketoses
2. Oligosaccharides
   - (*a*) Disaccharides
   - (*b*) Trisaccharides
   - (*c*) Tetrasaccharides

## MONOSACCHARIDES

**Structure.** *Aldoses.* The aldose monosaccharides, for simplicity of discussion, may be considered as straight-chain carbon compounds having an aldehyde group at one end and a primary alcohol group at the other, with one hydroxyl and one hydrogen attached to each of the intermediary carbons. Thus, an aldohexose is $CH_2OH \cdot (CHOH)_n \cdot CHO$.

*Ketoses.* The ketose sugars may be considered as straight-chain compounds with a primary alcohol group at each end of the chain and a ketone group, usually at carbon 2. Thus, a ketohexose is $CH_2OH \cdot (CHOH)_3—CO—CH_2OH$. There are four *d*-ketohexoses: psicose, fructose, sorbose, and tagatose. Each is structurally related to an epimeric pair of aldohexoses, the asymmetric carbon 2 of the aldose structure becoming a carbonyl group, C=O, whereas the configuration of the remaining three asymmetric carbons remains the same. Thus *d*-psicose is structurally related to *d*-allose and *d*-altrose, *d*-fructose to *d*-glucose and *d*-mannose, *d*-sorbose to *d*-gulose and *d*-idose, and *d*-tagatose to *d*-galactose and *d*-talose.

**Chemistry of the Monosaccharides.** *Chemical Properties.* Both the aldoses and ketoses are easily oxidized and hence act as reducing agents. They reduce ammoniacal silver nitrate to form a silver mirror, and warm alkaline copper solutions to cuprous oxide, a reaction widely used in the analysis of molasses and other sugar products. On mild oxidation with $Cl_2$ or $Br_2$, monobasic acids with the same number of carbon atoms are formed, the aldehyde end of the molecule being oxidized to carboxyl:

$$CH_2OH(CHOH)_nCHO \rightarrow CH_2OH(CHOH)_nCOOH$$

With strong oxidizing agents such as nitric acid, both ends of the carbon chain are oxidized to give a dibasic acid, while at the same time much of the acid is further oxidized to oxalic acid and carbon dioxide:

$$CH_2OH(CHOH)_nCHO \rightarrow COOH(CHOH)_nCOOH$$

The oxidation of sugars and especially sugar derivatives with periodic acid is an interesting case of specialized oxidation. Periodic acid oxidizes only adjacent hydroxyl groups to aldehyde groups. If three or more hydroxyl groups are adjacent, the intermediate ones are oxidized to formic acid. Hudson and his collaborators have used this reaction to great advantage in structural studies in the sugar group.

In alkaline solution a pair of epimeric aldose sugars and the structurally corresponding ketose are mutually interconvertible. Thus, starting with a weak alkaline solution of glucose, mannose, or fructose, all three will be found present after some hours at room temperature. In strong alkaline solution the reducing sugars undergo more drastic changes, a series of compounds called saccharinic acids being formed. In alkaline solution in the presence of air or oxygen, carbon dioxide, lactic acid, and a whole series of hydroxy acids may be formed. In cold dilute acid solution the sugars are quite stable, but heating with 12 per cent HCl results in a quantitative production of furfural from the aldopentoses, whereas aldohexoses yield hydroxy-methyl-furfural and levulinic acid.

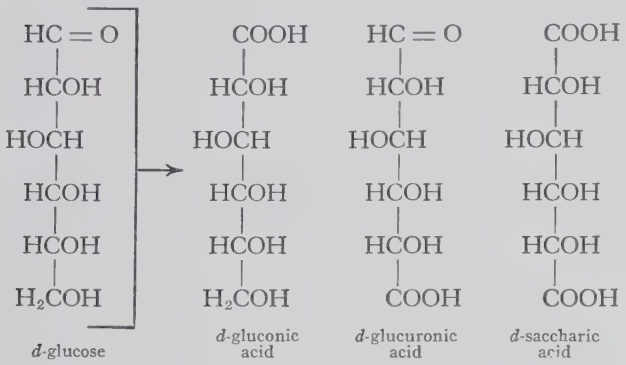
Since the aldose sugars possess both aldehydic and alcoholic groups, they react to some extent both as aldehydes and alcohols. As aldehydes they act as reducing agents, form oximes with hydroxyl amine, and phenylhydrazones with phenylhydrazine. When they are heated with an excess of phenylhydrazine, very insoluble compounds called phenylosazones are formed. In this reaction two eperimeric sugars and their structurally related ketose give the same phenylosazone. Thus, glucosazone is formed from glucose, mannose, or fructose. This osazone reaction is extremely valuable for identifying the sugar or sugars in a solution; Emil Fischer used it extensively in his epoch-making researches resulting in the elucidation of the configurational relationships of the simple sugars. As aldehydes the sugars may be readily oxidized to monobasic acids or reduced to the so-called sugar alcohols. In keeping with their alcoholic properties the sugars form esters with acids, acetals and ketals with aldehydes and ketones, and may be made to react with methyl iodide or dimethyl sulphate to give methylethers.

*Glycosides.* Of special interest in sugar chemistry is the reactivity of carbon 1. The hydroxyl attached to this carbon may be readily substituted by an aldoxy group to form the glycosides. These compounds are more stable than the parent sugars, since they are not so readily oxidized or reduced. They exist, as do the parent sugars, in $\alpha$ and $\beta$ modifications. When the hydroxy groups of the sugar molecule are protected, as by acetylation or benzoylation, the group on C1 may be replaced by a halogen, thus giving an extremely labile compound that will react with other sugars or hydroxylated compounds to form new sugars or new glycosides.

*Degradation and Synthesis.* The carbon-chain length of a reducing sugar may be increased or decreased. The cyanohydrin reaction is the classic method for increasing the chain length. Hydrogen cyanide may be added to reducing sugars to give nitriles which can be hydrolyzed to sugar acids, which may in turn be reduced to sugars having one more carbon in the chain than the original. By this synthesis a new asymmetric carbon atom is introduced, so that two isomeric sugars are formed from the one of lower carbon content. Several methods are employed for degrading a sugar to one of lower carbon content. Probably the simplest method is by oxidation of the calcium salt of the sugar acid with

hydrogen peroxide and ferric acetate. Since this is the reverse of the building-up reaction, either of two epimeric sugars will give one and the same sugar of one less carbon content. Thus, either glucose or mannose will be degraded to arabinose.

**Derivatives of the Monosaccharides.** *Acids.* Three types of sugar acids may be considered as derivatives of the aldose sugars by oxidation of the terminal groups on C1, C6, or both. For example, from glucose there may be derived two monobasic and one dibasic acid as formulated below:



*d*-glucose — *d*-gluconic acid — *d*-glucuronic acid — *d*-saccharic acid

The "onic" acids such as gluconic exhibit two properties of exceptional interest. They readily lose one molecule of water, forming lactones which crystallize readily. When they are heated to a high temperature with pyridine or quinoline, a rearrangement of the hydroxyl on C2 takes place to give an equilibrium mixture of the original acid and a new epimeric acid. For example, *d*-arabonic acid may be partially converted to *d*-ribonic acid, a reaction that has been extremely valuable in the synthesis of the vitamin riboflavin. The uronic acids, galacturonic and mannuronic, are building blocks for the naturally occurring substances pectin and alginic acid, respectively. Glucuronic acid is a scavenger in the animal body, uniting with certain types of poisonous substances and eliminating them by way of the urine.

*Alcohols.* By reduction of the terminal group on C1 for aldoses or the C2 group for ketose sugars, compounds are formed whose only functional groups are primary and secondary alcohols. This reduction is readily carried out with sodium amalgam or with hydrogen and a nickel catalyst. Many of these sugar alcohols are naturally occurring products. Sorbitol, from glucose or fructose, and mannitol, from mannose or fructose, are produced industrially for a wide variety of uses. Sorbitol is especially valuable as a raw product in the manufacture of vitamin C, ascorbic acid.

*Esters and Ethers.* The sugars are readily acetylated, propionated, benzoylated, and reacted on otherwise to form ester-type compounds, all the hydroxyl groups in the molecule take place in the reaction. These products are usually well-defined crystalline compounds. These derivatives of the reducing sugars exist in alpha and beta forms, as do the parent sugars. The acetates, benzoates, and toluene sulphonates have been valuable in synthetic-sugar chemistry. Glucose phosphate has been of particular interest, serving as the basis for the biological synthesis of starch and sucrose. With a few exceptions only the methyl ethers of the sugars, the methyl sugars, have been prepared. The reducing sugars cannot be directly methylated, but on treatment of the glycosides with methyl iodide and silver oxide or with dimethylsulphate, methyloxy groups are substituted for the primary and secondary hydroxyls. An extensive series of these methyl sugars has been prepared, such as 3-methyl glucose, 2-3-6-trimethyl glucose, 2-3-4-6-tetramethyl glucose, and so on. The importance of these methyl sugars in carbohydrate research and synthesis cannot be overestimated. Until their discovery and development, the advancement of certain phases of sugar, starch, and cellulose chemistry was at a standstill. No method was available for determining the ring structure in the monosaccharide units or the point of attachment of the monosaccharide units in compound sugars or polysaccharides. These methylated sugars have been the keys with which the organic chemist has unlocked many problems of carbohydrate structure.

*Anhydro Sugars.* As the name implies, anhydro sugars are those from which one molecule of water has been eliminated, by dry distillation or otherwise. The compounds fall into three classifications:

(1) Ethylent oxide type, in which the anhydro group is between C2 and C3, C4 and C5, or C5 and C6.

(2) Butylene oxide type, in which water has been eliminated between C2 and C5 or C3 and C6.

(3) Glucosan type, which may be three-, four-, five-, or seven-member ring compounds. The 1-6 anhydro sugars are easily hydrolyzed by acids, a property that makes them useful in the synthesis of various sugar derivatives. Mannosan has been used for the synthesis of disaccharides.

*Desoxy Sugars.* Desoxy sugars are exceptions to the general rule that the empirical formula for sugars is $C_m(H_2O)_n$. As the name implies, desoxy sugars are substances containing one less oxygen than is normally the case for a sugar compound. The desoxy sugars are of two types:

(1) The 2-desoxy sugars, in which the oxygen in the secondary alcohol on C2 is missing, as in desoxy glucose, $CH_2OH—(CHOH)_3—CH_2—CHO$.

(2) The methyl pentoses, in which the oxygen of the primary alcohol on C6 is missing, as in rhamnose, $CH_3(CHOH)_4—CHO$.

Both these types of sugars occur in natural products.

*Amino Sugars.* These sugars are aldohexoses in which a secondary hydroxyl has been replaced by an amino group ($NH_2$). Two occur extensively in natural products, namely, glucose amine or 2-amino glucose, and chondrose amine or 2-amino galactose. The former is obtained by hydrolyzing chitin from crab shells with strong HCl, whereas the latter may be obtained by the hydrolysis of nasal cartilage, tendons, and similar tissues. Other amino sugars, such as 3-amino glucose and 6-amino glucose, have been prepared by synthetic means.

**Individual Monosaccharides.** The naturally occurring or most important members of this group are described individually.

***Aldopentoses.*** d-*Ribose.* *d*-Ribose occurs in yeast nucleic acid and is important for the synthesis of the vitamin riboflavin.

l-*Arabinose.* *l*-Arabinose is widely distributed in plant products, especially in gums. It does not occur as the free sugar but is found in the polymeric araban.

d-*Arabinose.* *d*-Arabinose does not occur naturally but is readily prepared from *d*-glucose by the degradation reaction described earlier.

***Aldohexoses.*** d-*Glucose.* *d*-Glucose is the most important of all aldehyde sugars. It is the building block of starch and cellulose. It occurs in the free state in most fruits, vegetables, and plant juices. It is the sugar of blood, causing death if deficient and diabetes if superabundant. It is food for man, beast, and insects. It is fermentable by yeasts, bacteria, and fungi. The United States Pharmacopoeia (U.S.P.) designation for *d*-glucose is dextrose.

d-*Mannose.* *d*-Mannose occurs widely in nature as the

polymeric mannan. It is fermentable by yeasts but is not an important raw product for alcoholic fermentation. Pure mannose is said to have a slightly bitter aftertaste, in marked distinction to the pure sweet taste of other sugars.

d-*Galactose.* *d*-Galactose occurs in the polymeric galactan, abundant in the western larch and in a large number of natural gums. As a galactoside it is found in brain tissue, and combined with glucose it forms the disaccharide lactose, or milk sugar. Galactose has no important industrial uses, but by oxidation with nitric acid the relatively insoluble mucic acid, a potentially useful organic acid, is formed.

***Ketohexoses.*** d-*Fructose.* *d*-Fructose occurs in a great many fruits, plant juices, and saps. Combined with *d*-glucose it forms the easily hydrolyzable disaccharide sucrose. Since sucrose is so readily hydrolyzed by acids and enzymes, the products of its hydrolysis, *d*-glucose and *d*-fructose, generally occur at least in small quantities wherever sucrose is found. The mixture of equal parts of *d*-glucose and *d*-fructose is called invert sugar, which is the main constituent of honey. Fructose is the building block of the polysaccharide inulin, from which it may be obtained by acid hydrolysis. Fructose is said to be sweeter than sucrose, but cost of manufacture has hampered its commercial development.

**l-*Sorbose.*** *l*-Sorbose is found in the berries of the mountain ash, where it is probably produced by bacterial oxidation of *d*-sorbitol, a natural constituent of the berries. *l*-Sorbose is produced in quantity by bacterial fermentation of *d*-sorbitol for use as an intermediary product in the production of *l*-ascorbic acid, vitamin C.

## OLIGOSACCHARIDES

The oligosaccharides are subdivided into three groups: (1) disaccharides, (2) trisaccharides, and (3) tetrasaccharides, which, as their names imply, are composed of two, three, or four monosaccharide units. These relatively simple compound sugars may be called oligosaccharides, to distinguish them from the group of more complex, high-molecular-weight sugar polymers, such as starch, inulin, and cellulose, known as polysaccharides. The monosaccharide composition of the oligosaccharides was readily determined, and in those cases where a disaccharide does not display aldehydic or ketonic reactions the attachment must be between C 1 and $C^1$ 1 for two aldose monosaccharides or between C 1 and $C^1$ 2 for an aldoseketose combination. Until the introduction of the methylation reaction, little further could be learned concerning the structure of the compound sugars. However, by application of this reaction and by study of the methylated sugars and of their hydrolytic, oxidation and degradation products, within a few years the structure and configuration of many of the compound sugars was made clear. Column 3 of the table indicates the configuration of the sugar and the point of attachment of the monosaccharide units. Arabic numerals are used to denote the point of attachment of the nonglycosidic monosaccharide, which in the case of the reducing disaccharides is the component still possessing aldehyde properties, with C 1 of the other hexose component. The Greek letters alpha and beta denote the configuration of the glycosidic carbon.

Common Oligosaccharides

| *Name* | *Composition* | *Configuration* |
|---|---|---|
| Sucrose | Glucose<>fructose | 1-α-Glucoside-2-β-fructose |
| Trehalose | Glucose<>glucose | α, α-Diglucose |
| Maltose | Glucose<glucose< | Glucose-4-α-glucoside |
| Cellobiose | Glucose<glucose< | Glucose-4-β-glucoside |
| Gentiobiose | Glucose<glucose< | Glucose-6-β-glucoside |
| Lactose | Galactose<glucose< | Glucose-4-β-galactoside |
| Melibiose | Galactose<glucose< | Glucose-6-α-galactoside |
| Turanose | Glucose<fructose< | Fructose-3-α-glucoside |
| Raffinose | Galactose<glucose<>fructose | 2-β-fructose-1-α-glucose-6-α-galactoside |
| Melezitose | Glucose<fructose<>glucose | 1-α-glucose-2-β-fructose-3-α-glucoside |
| Gentianose | Glucose<glucose<>fructose | 2-β-fructose-1-α-glucose-6-β-glucoside |
| Stachyose | Galactose<galactose<glucose<>fructose | |

**Sucrose.** Sucrose is by far the best known of all the sugars, produced annually from sugar cane and beets by the millions of tons, and to a less extent from maple sap and certain species of palm trees. It possesses no aldehyde or ketonic properties, hence does not show mutarotation or reduce Fehling's solution. It is stable in dilute alkalies but is readily hydrolyzed by dilute acids or the enzyme invertase to a mixture of equal parts of *d*-glucose and *d*-fructose, called invert sugar.

**Trehalose.** Trehalose, another nonreducing disaccharide, is found in certain fungi which contain no chlorophyll. The best source of this sugar is the resurrection plant, which grows abundantly in southwest North America.

**Maltose.** Maltose is a dissaccharide which, though seldom encountered in the crystalline form, is a close competitor of sucrose in the matter of human happiness and well-being. It is a hydrolytic product of starch and is one of the principal components of confectioners' glucose or corn sirup, and the principal component of a new and sweeter type of corn sirup called sweetos. Maltose is a reducing sugar and shows the characteristic reactions of aldose sugars.

**Cellobiose.** *Cellobiose* sugar is an intermediate in the breakdown of cellulose to glucose, thus a unit of the cellulose molecule as maltose is a unit of starch.

**Gentiobiose, Melibiose, Turanose.** *Gentiobiose, melibiose,* and *turanose* are disaccharide portions of the trisaccharides gentianose, raffinose and melezitose, respectively, and are prepared by the hydrolysis of these sugars. Gentiobiose has been identified as a product of the drastic hydrolysis of starch, but melibiose and turanose have been obtained only by the hydrolysis of their respective parent trisaccharide. Gentiobiose and melibiose are aldehyde sugars, whereas turanose is ketone sugar.

**Lactose.** *Lactose,* a disaccharide occurring as a major constituent of milk, is an important article of diet. It crystallizes readily and can be easily prepared from whey. However, the pure crystalline product until recently has not been extensively used except in prepared infants' food. With the extensive manufacture of penicillin, the demand for pure lactose greatly increased. It is a major item in the mash for the fermentive production of this antibiotic. Lactose is found exclusively in the animal kingdom in contrast to all other sugars, which are of purely vegetable origin.

**Raffinose.** *Raffinose* is a trisaccharide which occurs extensively in sugar beets and in seeds, leaves, roots, and plant exudations caused by insect injury. Cottonseed is a particularly rich source. It is a nonreducing sugar, stable in alkaline solution; but since a portion of the molecule is the disaccharide sucrose, it is readily hydrolyzed, yielding fructose and melibiose.

**Melezitose.** Melezitose is a trisaccharide that occurs as an exudation or manna on the bark, leaves, and twigs of a number of trees, especially evergreens such as the Douglas fir and pines. Under certain climatic conditions it occurs so extensively that bees collect it, probably by mistake, and deposit it in the comb. Being a sugar of low solubility, it crystallizes

in the honey, forming a product with little sweetness and of a gritty consistency, to the distress of the commercial apiculturist. Melezitose is another nonreducing sugar. Since it contains the sucrose linkage, it is rather easily hydrolyzed to turanose and glucose.

**Gentianose.** Gentianose comprises about 20 to 25 per cent of dried gentian root. It has no value industrially; on the other hand, it is not a source of annoyance as are the other trisaccharides, raffinose and melezitose. It is also a nonreducing sugar, but since it contains the sucrose linkage, it is readily hydrolyzed by acids and invertase.

**Stachyose.** Stachyose, the sole member of the tetrasaccharide group, is another naturally occurring sugar of purely scientific interest. It has been found in the tuber of the Japanese artichoke, in the manna of the ash tree, and in the seeds of many legumes. *See also* STARCH; SUGAR BEET; SUGAR CANE. J. K. D.

**SUGAR MAPLE.** *See* MAPLE.

**SUICIDE,** the taking of one's own life. In the United States, suicide is numerically unimportant as a cause of death, accounting in 1944 for slightly less than one per cent of all deaths. The suicide rate in the United States has fluctuated with wars (decrease), prosperity (decrease), and depressions (increase) to an extent that makes it difficult to state a long-term trend, although indications are that it is slightly upward. During periods of peace and economic stability the rate tends to be about 14 or 15 per 100,000 of the population; during both World War I and II it decreased to about 10 per 100,000; during the prosperous 1920's it stood at 13 or 14; and during the depression of the 1930's it rose to 17.

In the United States, men commit suicide almost three times as frequently as women, but women make more unsuccessful suicide attempts than men. The rate for whites is approximately four times the rate for Negroes, while foreign-born whites have a higher rate than native-born. The rate increases with age. In 1944, the rate went from 0.4 per 100,000 for children from 10 to 14 years old to 27.2 for persons from 65 to 69 years old. Thereafter the rate decreased slightly. Cities have a higher rate than rural areas. Within a city, the suicide rates follow a characteristic pattern, being high in the disorganized areas near the central business district, such as slums, "homeless men" areas, and rooming-house areas, and increasingly lower toward the periphery of the city where family and community life is more stable.

**Europe.** Each nation has its own pattern of suicide. Ireland, with three suicides per 100,000, has one of the lowest rates of any civilized country. In the prewar period, the rate in Spain was about four, and in Italy about eight. Other nations with rates well below those for the United States are Canada, Norway, Netherlands, England, Wales, Australia, Bulgaria, Lithuania, New Zealand, Portugal, Romania, and Scotland. During the late 1930's, Austria had the highest rate, with about 39 suicides annually per 100,000 people. Other high-rate countries are Hungary, Germany, Czechoslovakia, Switzerland, Estonia, Denmark, and France. European countries having rates close to those for the United States are Belgium, Finland, and Sweden. Thus, the rates for various European nations prior to World War II varied from 3 to 38. These rates were not closely related to the racial classification of the population. The three nations with the lowest rates are Roman Catholic, whose church forbids the burial of a suicide in consecrated ground. The differences in rates are probably related, also, to internal social conditions and attitudes toward suicide as a method of meeting personal problems.

**Orient.** Japan, whose annual rate from 1875 to 1936 varied between 15 and 22 suicides per 100,000 population, differs from European countries in having both personal and institutionalized forms of suicide; that is, certain social situations demand that the person involved commit suicide regardless of his personal inclinations. India formerly had an institutionalized form of suicide, called suttee: the burning of a widow upon her husband's funeral pyre. This practice, though banned by the British in 1829, was continued in some sections of India until late in the nineteenth century.

**Suicide Among Primitive People.** In their native state, primitive peoples rarely commit suicide, probably because in the small, closely unified primitive community few personal problems arise. Some tribes have institutionalized suicides, such as those of widows and servants upon the death of a chieftain. The Eskimos encouraged suicide of the very old who had become a burden upon the community. R. S. C.

**SUIFU** or **IPIN** [swe'fu'; i'pi'n], formerly known as Suchow, a city in the southern part of Szechwan Province, China. It is situated 140 mi. southwest of Chungking at the junction of the Min River and the Kinsha-kiang (Golden Sand River), the latter being the name for the upper section of the Yangtze River. From Suifu down, the river is called the Yangtze. About 1,600 mi. from the mouth of the Yangtze, Suifu is the upper terminus for shipping from Ichang (Hupeh Province). Suifu is also the starting point for a projected 859-mi. railway to Kunming (Yünnan Province) along an ancient trade road which used to require a month to travel. The roadbed for the planned railway had been laid during World War II, but construction had never been accomplished, owing to the unstable political situation of China. Belonging to the Chienwei prefecture in the Han Dynasty (206 B.C.-A.D. 220), this city was named Nanchi in the Sung Dynasty (A.D. 960-1297) and Suchow in the Ch'ing (Manchu) Dynasty (A.D. 1644-1912). Ipin is the official name given to this city by the Chinese republican government. Located in the fertile Yangtze Valley, the Suifu region produces in abundance rice, sugar cane, tobacco, tangerines, oranges, and apples. Wine and tobacco manufacturing constitute essential industrial activities in the city. As an entrepôt for handling products destined for the lower Yangtze, Suifu thrives on trade in products from western Szechwan and Yünnan provinces, such as silk from Chengtu, insect wax from Loshan, salt from Tzeliutsing, and medicinal herbs from Yünnan Province. Pop. (est.), 150,000. A. C. T.

**SUITE** [swi't], a set of pieces, usually dance types, composed for one or more instruments and contrasted in tempo, meter, and mood. The practice of grouping two or more contrasting dance movements was well established in instrumental music by the sixteenth century. One of the basic groupings consisted of a stately, slow, and gliding floor dance in even meter, followed by a lively jumping dance in triple meter; thus a pavane would be followed by a galliard, and a passamezzo by a saltarello. The second dance was often a variant of the first, thematically speaking, and this sort of relationship between the suite movements was fairly common in the history of the suite even up to the time of J. S. Bach, in whose work it can be observed in the D-minor partita for solo violin. In lute books of the sixteenth century three such dances are frequently grouped together.

The fully developed suite, which culminated in the great Bach suites of the eighteenth century, was the composite product of the varied experiments with these groupings

that had occurred during the seventeenth century in France, Italy, Germany, and England. In France, these experiments took the form of lute, harpsichord, or clavichord pieces; in Italy, of chamber sonatas; in England, of vigorous, characteristically English suites by Henry Purcell and his contemporaries; in Germany, of diverse forms, among which are the earliest examples of the four-movement form later developed in the time of Bach.

Bach's numerous suites for keyboard and other solo instruments, for chamber groups, and for orchestra mark the peak of suite literature and are unexcelled in scope and expressiveness. Well before Bach's time the dance movements of the suite had become artistic idealizations of the actual dances that served as their prototypes, but in most of the movements of the Bach suite the rhythmic element is still important. With rare exceptions, these movements are all in the same key and the form of each is two-part, with the first modulating to a related key and the second returning to the tonic, often by a more circuitous route. The treatment generally involves a sort of loose interplay of motives, with a tendency toward ornate, rhapsodic freedom in the slower movements and a use of square meter in the faster movements.

The Bach suite consisted of four basic movements. The allemande, ordinarily a dance of moderate tempo in even meter, began with a short upbeat. The courante, which followed it, was a running dance in triple or duple-compound meter, or often both. The saraband was a slow, serious dance in triple meter, characteristically having a dotted quarter on the second beat. The gigue (from the Irish "jig"), which concluded the suite, was a lively dance in compound triple meter whose character was often taken over at a later date for the finales of sonata music. Bach went beyond this basic structure, however, and ordinarily inserted one or more additional movements, such as the bourrée, air, or loure, between the saraband and gigue.

After Bach the idea of the suite was carried over to a certain extent in the Classic *divertimenti,* and the term "suite" itself was still used from time to time, especially in the later nineteenth century, but gradually lost the fixed meaning indicated by the standard Baroque dance movements, for these were no longer composed. Typical of sundry uses of the term as indicating merely a loose grouping of separate pieces are Bizet's incidental music for *L'Arlésienne* (1872), Debussy's *Petite suite* for piano duet (1888), and Stravinsky's *Petrouchka suite* (1912).

W. S. N.

**SUIYÜAN** [swe′yüɑ′n], a Chinese province situated south of Outer Mongolia and flanked by Chahar on the east and Ningsia on the west. Its southern boundary touches Shansi and Shensi provinces. Suiyüan has an area of 134,181 sq. mi. Kweisui is the provincial capital.

**Topography and Climate.** The central part of the province is a highland formed by the western extension of the Yingshan range. Its highest peak, the Oongkung Shan (about 15,000 ft.), is north of Kweisui. The Hwang Ho (Yellow River) separates Suiyüan from Ningsia in the southwest, and before it enters Shansi, in the southeast, the river forms a huge bend in the shape of an inverted U, which is called Houtao, or the Hwang Ho Bend. The banks along the bend provide the richest farming region in the northwest. South of the bend is the Ordos Grassland, inhabited by Mongols. North of the bend is a contiguous part of the Mongolian highland. The climate in Suiyüan has sharp contrasts between summer and winter and between day and night. Winter is bitterly cold, especially north of the Yingshan range; the temperature drops to —26° F. In summer it rises to 100° F. Rainfall in central Suiyüan is about 13 in. a year.

**Economic Resources and Activities.** Agricultural activity in the Hwang Ho Bend area is limited by the need for irrigation. The adjacent silt land is irrigated by a system of fourteen main canals watering a total of 198,000 acres. The principal crops are barley, oats, millet, kaoliang, and hemp, more than sufficient for the farming population. The chief resources available for export are coal, alkali, salt, livestock, wool, and furs.

The only railroad in Suiyüan is the Peiping-Suiyüan Railway, which connects Paotow, the leading trade center in central Suiyüan, with Peiping in Hopeh Province. Imperial roads and caravan routes still play an important role in Suiyüan's communications, and the camel continues to be the best means of transportation over the grassland and deserts.

**Population and Cities.** The inhabitants of Suiyüan are largely Chinese, and the Mongols are the largest minority group. The Mongols are divided into two leagues, the Ulanchab and the Ikhachao, each of which is subdivided into several smaller political divisions, or banners. The Mongols are mostly nomadic and wander from place to place with their livestock wherever pasture is available. The dialect is Western Mongolian.

Kweisui, the capital city on the Peiping-Suiyüan Railway, is the converging point of the road network to Kansu, Sinkiang, Ningsia, and Tsinghai, making it one of the most important towns in northwestern China. Paotow, at the western terminus of the railroad, is a mining and wool-producing center; and Pailingmiao, in northern Suiyüan, is a prosperous town on the Sinkiang-Suiyüan camel caravan route.

**History.** Suiyüan became an integral part of China during the Han Dynasty (206 B.C.-A.D. 220). The whole territory was then divided into four states: Tinghsiang, Yunchung, Sofang, and Wuyuan. At the beginning of the thirteenth century, when the Mongols gained power, this region was known as Tatung Route. During the Manchu Dynasty, Suiyüan became a part of Inner Mongolia, together with Chahar and Jehol, and in 1928 it was declared an independent province. The growth of the Mongolian autonomous movement brought into existence the Mongolian Autonomous Political Council, established at Polingmiao in 1934, to direct Mongol activities in Chahar and Suiyüan under Mongol princes. A reorganization took place in 1936 and Chahar and Suiyüan provinces each received separate councils. Pop. 1947, 2,084,000.

**SUK.** *See* African Peoples.

**SUKKOTH** [sukо′th], or Feast of Tabernacles, a Jewish festival lasting for nine days, beginning on the fifteenth day of the Hebrew month Tishri, which occurs in the early autumn. The first two days and the last two days are full holidays; on the five intermediate days, called *hol ha-moed,* work is permitted.

Marking the season of the fruit harvest and thus the end of the agricultural year, Sukkoth, also referred to as *hag ha-asif* ("Feast of the Ingathering"), was the principal Hebrew agricultural festival of Biblical times. Since the destruction of the Temple (A.D. 70), Sukkoth has been celebrated by the inclusion of special liturgy in the synagogue services, by processions in the synagogue with the *lulab* and *ethrog,* and by eating in a *sukkah* especially built in the honor of the festival. The *sukkah* is a simple structure with a thatched roof, suffi-

ciently open to permit the sky to be seen, and customarily decorated with fruits of the season. The *sukkah* may probably be traced to the ancient practice of living in the field during the harvest, but it is traditionally commemorative of the temporary dwellings of the Hebrews in the wilderness. In both the ancient and modern observance of Sukkoth the motif of thanksgiving has been stressed.

The last three days of Sukkoth have individual names and characteristics. The seventh day is called Hoshanah Rabbah; the eighth day, Shemini Atzereth; and the ninth day, Simchath Torah. On the latter day the annual reading of the Pentateuch or Torah (which is divided into weekly portions) is completed and begun anew. In Palestine, the features of Shemini Atzereth and Simchath Torah are combined on the eighth day, which is there celebrated as the last of the festival. *See also* ETHROG; LULAB. D. G. and G. W.

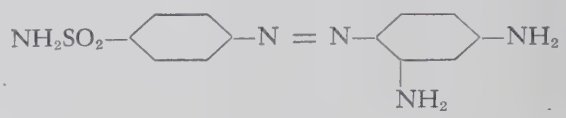
**SUKKUR** [sʊ′kkʊr], the chief city of the Sukkur District in northeastern Sind Province, in western Pakistan, about 240 mi. northeast of Karachi, in a hot desert region where the average rainfall is between 1 and 10 in. annually. An important commercial center, the city is located near a gorge on the west bank of the Indus River, famous as the site of the great Lloyd or Sukkur Dam, one of the largest irrigation dams in the world. Completed in 1932, it irrigates about 7,500,000 acres of fertile alluvial soil along the Indus, where wheat and millet are grown. The city has cotton ginning, silk milling, dyeing, rice and flour milling, and other industries. Pop. 1952, 77,057.

**SULAIMAN MOUNTAINS** [sʊlimɑ′n], a range located in central Pakistan, extending southward from the Pamir Knot and Hindu Kush Range. The average elevation is about 5,000 ft., but there are many higher peaks, some of more than 11,000 ft., on the border of northeastern Baluchistan. Twin peaks known as Takht-i-Sulaiman, meaning "throne of Solomon," reach 11,100 ft. in height. J. E. F.

**SULEIMAN I** [sülemɑ′n] (c.1496-1566), called the Magnificent, sultan of the Turkish Empire, was born in Constantinople about 1496, the son of Selim I. A cultured man, he encouraged learning and the arts. He is generally considered the greatest of the sultans, under whom the Ottoman Empire reached its height. The improved system of government during his reign was actually the work of his viziers, especially the famous Ibrahim Pasha who was in control from 1523 to 1536. When Suleiman succeeded his father as sultan in 1520 he set out on a career of conquest. In 1521 he captured Belgrade, after invading Hungary to force the payment of tribute which had been withheld. Five years later the Hungarian king, Louis II, was killed and his army completely defeated at the battle of Mohács. In 1529 Suleiman laid siege to Vienna but was forced to withdraw. In the meantime his fleets had taken the island of Rhodes from the Knights of St. John in 1522, and had gone on to conquer Tripoli and Algiers in North Africa. Beginning in 1533 a series of wars against Persia won Mosul, Tabriz, Baghdad, and much other territory for the Ottoman Empire. In 1536 the sultan made a formal alliance with Francis I of France against the Hapsburgs, and gave France sole Occidental participation in the commerce of the Levant. He failed to take Malta from the Knights of St. John in 1565, and on Sept. 5, 1566, he died during the siege of Szigetvár in Hungary. F. C. H.

**SULFONAMIDES** [sʌlfonæ′midz], a group of chemical compounds used in the treatment of bacterial diseases. The development of the sulfonamides was perhaps the greatest single advance in medicine in the twentieth century. In their wake have come the antibiotics, including penicillin, tyrothricin, streptomycin, polymyxin, chloromycetin, aureomycin, and terramycin, which, however, did not entirely displace the sulfonamides.

Fritz Mietzsch and Joseph Klarer, chemists, and Gerhard Domagk, a pharmacologist in the laboratories of the I. G. Farbenindustrie in Wuppertal-Elberfeld, Germany, are credited with the synthesis of the sulfonamides in 1931. The initial product, effective in experimental animals, specifically mice, was prontosil, a coloring matter or dye:



The compound was shown to be broken down in the body to

sulfanilamide—para-aminobenzenesulfonamide, which is not a dye.

From this basic formula have been derived thousands of compounds with varying action in the test tube, and in mice and other animals, against bacterial infections. The following derivatives are of greatest importance, have had the widest use, and have been shown to be most effective in non-toxic dosage: sulfathiazole, sulfapyridine, sulfadiazine, sulfamerazine, sulfamethazine (now known as sulfamezathine), sulfaquinoxaline, and sulfaguanidine.

They interfere with the utilization of PABA (para-aminobenzoic acid), an essential metabolite for the growth of most bacteria. The effect of the sulfonamide can be overcome by increasing the concentration of PABA in growth medium. Sulfonamides have greatest use in treating septicemias (blood poisoning) and general infections. The sulfonamide is absorbed and establishes itself in the blood stream where it exerts its effect against bacteria in the blood, as well as in tissues fed by blood.

Sulfonamides are excreted by the kidneys and, to a limited extent, by other excretory and secretory tissues.

Sulfonamides are primarily bacteriostatic, rather than bactericidal. They interfere with bacterial respiration, growth, and reproduction, and permit active phagocytosis, or destruction of bacteria by white blood cells. They have greatest effect against rapidly growing bacteria and therefore produce most dramatic results in the treatment of acute bacterial diseases. In many species, the effect of the sulfonamide is in direct ratio to its concentration.

For the most part, sulfonamides are insoluble in water at neutral pH, and, depending on the compound, have greater solubility when the solution is made acid or alkaline. Most sulfonamides used in solution today are sodium salts prepared by adding caustic soda—NaOH—to suspensions of the compound.

Not all bacteria are susceptible to sulfonamides. They are regularly used for the treatment of bacterial diseases, in man and animals, that are caused by streptococci, staphylococci, many gram-negative and gram-positive bacteria, and protozoa such as coccidia. C. R. S.

**SULFUR.** *See* SULPHUR.

**SULLA, LUCIUS CORNELIUS** [sʌ′lə] (138-78 B.C.), Roman statesman and general. Sulla first won his spurs

in Africa, where he served during 107-106 B.C. as quaestor in the army of Marius and brought about the capture of King Jugurtha of Numidia. In 92 B.C., as propraetor in the eastern Mediterranean, he was instrumental in halting the first advances of Mithridates of Pontus toward the Aegean. In the Social War of 90-88 B.C. Sulla was the most successful of the Roman generals, a fact which brought him to the consulship in 88 B.C. In renewed operations against Mithridates in Greece and Asia Minor shortly thereafter, Sulla again demonstrated his military genius by driving Mithridates from Greece and ultimately forcing him to sign a peace treaty wholly favorable to Rome. While Sulla was absent from Italy the Marian (popular) party gained control of Roman politics, and his return to the peninsula in 83 B.C. touched off a bitter civil war in which Sulla and his senatorial partisans overwhelmed the popular party. Sulla then consolidated the conservative victory by wholesale executions and confiscations, which broke the power of the Marians for many years. Between 82 and 79 B.C. Sulla held the position of dictator, an office which had formerly been limited to a term of six months. As supreme head of the state, he secured the passage of reactionary legislation which practically barred the equestrian class from any real participation in the government, while direction of the affairs of state became almost a monopoly of the senatorial group. Broken in health, Sulla at last resigned his dictatorship and died in retirement in 78 B.C. T. B. J.

**SULLIVAN, SIR ARTHUR SEYMOUR** (1842-1900), English composer, was born in London on May 13, 1842, of Irish parentage. His father was a musician. Sullivan's musical career began in 1854, when he became a Chapel Royal choir boy. He continued his musical education as a scholarship student at the Royal Academy of Music (1856) and the Leipzig Conservatory (1858). His first published composition was an anthem issued in 1855, but he had his first success as a composer in 1862 with his incidental music to Shakespeare's *The Tempest.* Between 1855 and 1875 the composer added to his musical experience by serving as organist choirmaster, and conductor in Glasgow, and at St. Michael's, Chester Square, in London (1861-1872), and by visiting Vienna to assist in the recovery of lost Schubert manuscripts.

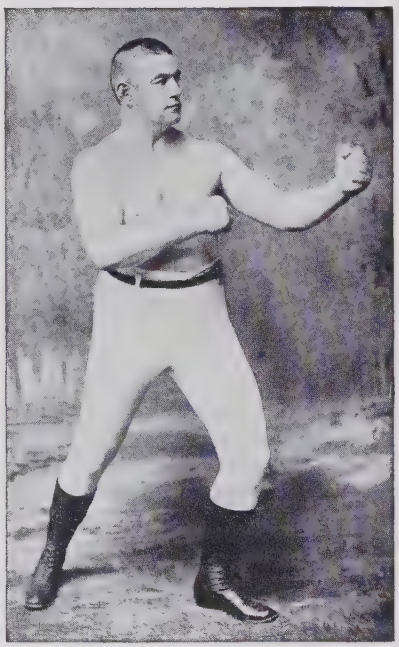
*SIR ARTHUR SEYMOUR SULLIVAN*

BROWN BROTHERS

From 1875 to 1896 the London stage saw the production of thirteen comic operas by Sullivan, with librettos by W. S. Gilbert. The sprightly cleverness of Gilbert's lyrics, together with Sullivan's flair for the theatre and his mastery in setting the English language to music, brought into existence a repertoire of stage works unequalled in their field. The most enduring of these, with the dates of their first performances, are *Trial by Jury* (Mar. 25, 1875), *H. M. S. Pinafore* (May 25, 1878), *The Pirates of Penzance* (Dec. 31, 1879), Patience (Apr. 23, 1881), *Iolanthe* (Nov. 25, 1882), *The Mikado* (Mar. 14, 1885), *Ruddigore* (Jan. 22, 1887), *The Yeomen of the Guard* (Oct. 3, 1888), and *The Gondoliers* (Dec. 7, 1889).

Sullivan's creative output was large and varied. In addition to the comic operas he wrote a grand opera, *Ivanhoe,* several concert overtures, an "Irish" symphony, several cantatas and oratorios, many hymns, among them *Onward, Christian Soldiers,* and some very successful songs, both secular and sacred, including *The Lost Chord.* Yet it is in the operettas that the bulk of his output lies and on them that his fame rests. In 1883 Sullivan was knighted by Queen Victoria in recognition of his contribution to the world of music. After his first successes Sullivan lived the life of a Victorian gentleman of means and culture. He knew most of the great European musicans of his time and was a friend of members of the royal families of England and France. He died in London Nov. 22, 1900. *See also* SAVOY OPERAS. L. Bu.

**SULLIVAN, JOHN LAWRENCE** (1858-1918), American pugilist, was born in Roxbury, Mass., Oct. 15, 1858. He attended local public schools, studied for a short time at Boston College, and then worked as a plumber, tinsmith, and professional baseball player. In 1878 he began a career as a boxer and won the world's heavyweight championship under London Prize Ring rules (bare knuckles) in 1882. Thereafter he was never defeated in a bare-knuckle fight and was the last of the champions in this form of boxing. Under the management of Billy Madden he made many exhibition tours, boxing by Marquis of Queensberry rules. He offered a prize of $100 (later $500) to any man who could stay four rounds with him, and although no one accomplished this feat the exhibitions helped to popularize boxing in the United States. Sullivan's last fight in defense



*JOHN L. SULLIVAN*

BROWN BROTHERS

of his bare-knuckle title was in 1889 in Richburg, Mass., where he won from Jake Kilrain in 75 rounds.

The first battle for the heavyweight championship of the world under Marquis of Queensberry rules was fought by Sullivan and James J. Corbett in 1892 in New Orleans. Sullivan's bare-knuckle title was not at stake, but Corbett, by winning by a knockout in 21 rounds, became the first Queensberry champion. Sullivan appeared in the ring only once after that, in an exhibition bout with Tom Sharkey in 1896. He fought a total of 37 matches, winning 12 by knockouts and 20 on decisions. Three matches ended in draws, one with no decision, and he was knocked out only once. He died in Abington, Mass., Feb. 2, 1918. C. W. D.

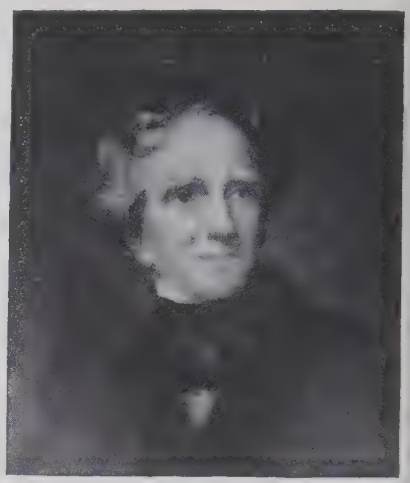
**SULLIVAN, LOUIS HENRI** (1856-1924), American architect, was born in Boston, Mass., Sept. 3, 1856, of Irish and Swiss-French parentage. He attended the Massachusetts Institute of Technology and the Ecole des Beaux Arts, Paris. He began his architectural practice at Chicago in 1880, forming a partnership there with Dankmar Adler in 1881. This partnership lasted until Adler's death in 1900, after which Sullivan practiced alone. From the beginning, Sullivan cut loose from tradition and outworn convention. He was a pioneer in modern architecture, particularly as illustrated in the skyscraper. He gave close study to problems of acoustics and skeletal construction but was even more concerned with abstract form. In addition to the structural excellence of his buildings, their exteriors evidence creative fertility of design.

Sullivan's Wainwright Building, St. Louis, built in 1890 of terra cotta and glass hung on an iron skeleton, was an early skyscraper. In its masterful relating of form to function without too severe a functionalism, it served as a criterion for later tall buildings throughout the United States. Other notable buildings by Sullivan were the Chicago Auditorium, 1889, influenced by H. H. Richardson; Pueblo, Colo., Opera House, 1890; Wainwright Tomb, St. Louis, 1892; Transportation Building, World's Columbian Exposition, Chicago, 1893; Chicago Stock Exchange Building, 1894; Prudential Building, Buffalo, 1895; Bayard Building, New York, 1898; Schlesinger & Mayer Department Store (later Carson Pirie Scott), Chicago, completed in 1904; Henry Babson estate, Riverside, Ill., 1907; and National Farmers Bank, Owatonna, Minn., 1908.

From 1886 to 1923, Sullivan made vigorous contributions in writing and in lectures to the arts, education, and democracy. His most noteworthy and popular book, *The Autobiography of an Idea* (1924), is an account of his life and of the dominant inner spirit that controlled it. Of his many essays, *What Is Architecture?* is of special importance. Sullivan died in Chicago on Apr. 14, 1924. G. G. E.

**SULLIVAN,** a city in southwestern Indiana, the county seat of Sullivan Co., situated 27 mi. south of Terre Haute. Sullivan was founded in 1842 and incorporated in 1909. A mayor and city council administers the city government. The Illinois Central and the Chicago & Eastern Illinois railroads provide transportation. The surrounding region has coal fields and oil wells, and Sullivan is a shipping market for these natural resources and for the grain grown in the district. Machine shops, hatcheries, and a cheese factory are located in the city. Pop. 1950, 5,423.

**SULLY, THOMAS** [sʌ'li] (1783-1872), American painter, was born in June 1783, at Horncastle, Lincolnshire, England. Brought to America in 1792, Sully grew up in Charleston, S. C., but he made his home in Philadelphia after 1808. The years 1809 and 1810 he spent as a student with Benjamin West in London. Sully's graceful style made him one of the most popular portrait painters of his day, particularly in the second quarter of the century. Among his most celebrated sitters were LaFayette, Queen Victoria, and the actress Fanny Kemble, as well as many outstanding American political figures, including three presidents, Jefferson, Madison, and Jackson. Sully was also an accomplished miniaturist. He died in Philadelphia, Nov. 5, 1872. E. B. S.



*THOMAS SULLY*

COURTESY OF THE HISTORICAL SOCIETY OF PENNSYLVANIA

**SULLY PRUDHOMME** [sü'li' prü'dɔ'm], pseudonym of René François Armand Prudhomme (1839-1907), French poet, was born Mar. 16, 1839, in Paris. He studied the sciences and became a civil engineer, but, growing discontented in this career, he became a clerk in a notary's office, seeking leisure to write poetry. At first, he wrote sentimental verse in which he analyzed his melancholy. The *Stances et poèmes* (1865) ("Stanzas and Poems") contained some poems such as *Vase brisé* ("The Broken Vase"), which were to appear in many school textbooks. They were written in a sentimental strain and in an elegant and correct style, characteristics which appeared in his later books, *Les Epreuves* (1866), *Les Solitudes* (1869), *Les vaines tendresses* (1875).

In 1869, Sully Prudhomme translated the first book of Lucretius and, in a preface, expressed his interest in philosophical and scientific poetry. However, he preached in his poetry that the way to happiness lies through the practice of brotherly love and virtue. Most of his compositions are mere developments of commonplaces on justice, happiness, and virtue. But he wrote also a long poem, half lyrical, half didactic, on life after death, and in 1876 he published, in the *Revue des deux mondes,* a poem in memory of three balloonists who had met death in their heroic endeavor to reach the stratosphere. After 1888 he devoted himself to philosophy, and he was an early and ardent Dreyfusard. He died in Paris, Sept. 7, 1907.

He was elected to the Académie Française in 1881 and received the Nobel Prize in 1901. After his death his poetry came to be considered cold and prosaic, and his reputation sharply declined. R. Ta.

**SULMONA** [sulmo'nɑ], a communications center in the province of L'Aquila, Abruzzi e Molise, in central Italy. It is situated at the southeast corner of an intermountain basin (the verdant Conca Peligna) on the Gizio River, an affluent of the Pescara, at 1,320 ft. above sea level, about 75 mi. east of Rome. It is surrounded on all sides by moun-

tains, including La Maiella to the east. A small industrial center, Sulmona owes its importance primarily to its position on the principal historic route from Rome to the Adriatic on the Via Valeria where it crosses another highway, paralelling the Apennines, from Aquila to Benevento and Naples. These ancient routes are followed by railways.

The town, strung out between the Gizio and Vella rivers, contains several interesting monuments, including the Cathedral of San Ponfilo; the Church of San Francesco della Scarpa, erected in the thirteenth century by Charles of Anjou but later reconstructed after an earthquake, a phenomenon to which the region is frequently subject; the Church and Palace of Santa Maria Annunziata, begun in 1415 but containing elements of both Renaissance and Gothic detail; and a statue of Ovid, a native of the city.

Sulmona was a city of some consequence in pre-Roman and Roman times, when it was known as Sulmo. After a period of obscurity, it reached its greatest glory under the Hohenstaufens and Angevins in the thirteenth and fourteenth centuries. In 1294 the hermit-pope Celestine V was crowned in its cathedral. Pop. (off. est. 1947), 23,729, including suburbs. R. G. W.

**SULPHUR** [sʌ'lfər], symbol S, atomic number 16, at. wt. 32.066. Monoclinic sulphur density is 1.957, m.p. 119.0°C., b.p. 444.6°C.; rhombic sulphur density is 2.07, m.p. 112.8°C., b.p. 444.6°C. Sulphur, called the same in Latin, is the second element in Group VI-B in the periodic table. It follows oxygen and, in turn, is followed by selenium, tellurium, and polonium. Its atom has two completed shells of electrons (2,8) and an outer shell containing 6 electrons. Sulphur does not give up its electrons to other elements, hence it is nonmetallic in nature. Since it readily shares its electrons with other nonmetals, it sometimes has a positive valence. One of the outstanding distinctions of sulphur is its ability to form oxides ($SO_2$ and $SO_3$) by sharing electrons (co-ordinate covalence) and acquiring valences of +4 and +6. These oxides are stable, and their derivatives are among the most important compounds that the chemist knows. This behavior is all the more remarkable because, as a rule, elements near each other in the periodic table do not combine readily.

**Occurrence.** Sulphur is found in a few localities in the uncombined state, and from these a large proportion of the commercial sulphur is obtained. In addition there are vast supplies of sulphide ores of the metals, such as lead, zinc, copper, and iron (pyrites). In winning these metals from their ores they are usually freed from sulphur by heating in the presence of oxygen. Under these conditions sulphur dioxide is formed, which frequently is allowed to go to waste. In addition to the sulphide ores, sulphur is extensively found in sulphates such as calcium sulphate (gypsum) or barium sulphate (heavy spar). Soluble sulphates such as those of magnesium and sodium are present in ocean water and many mineral waters. Hydrogen sulphide is present also in some mineral waters, forming "sulphur waters."

Commercial sulphur may be obtained from smelter, coke-oven, refinery, fuel, or natural gases. Sulphur from native underground deposits is melted by high-pressure steam and brought to the surface by compressed air and pumps; by the Frasch process, an ingenious system of concentric pipes, sulphur of 99.5 per cent purity is obtained.

Texas and Louisiana supply most of the elementary sulphur used in the United States. Spain, Italy, Japan, Chile, Russia, Norway, and Sweden produce quantities of sulphur and pyrites.

**Forms.** In its familiar forms, sulphur is either a yellow granular powder or a brittle crystalline mass, without odor or taste, insoluble in water. Sulphur can be prepared in various allotropic forms, which differ materially in color, solubility, and chemical behavior.

*Crystalline.* There are two crystalline forms. The first of these, rhombic sulphur, is best prepared by allowing its solution in carbon disulphide to evaporate at room temperature. The crystals are diamond-shaped, light-yellow in color, translucent, and readily soluble in carbon disulphide. This is the stable form of sulphur below 96° C., to which the other allotropic forms tend to change on standing. When molten sulphur is allowed to cool in cylindrical molds, it forms rhombic sulphur with large crystals distorted by crowding. This is the material called brimstone in commerce. The second crystalline form, monoclinic sulphur, stable above 96° C., forms long needlelike crystals, transparent, and soluble in carbon disulphide. On standing, these crystals revert to the yellow rhombic form.

*Noncrystalline.* Solid sulphur exists also in two noncrystalline forms. The first, colloidal sulphur, or milk of sulphur, is prepared by precipitating sulphur from solution, for example by boiling sulphur with lime, filtering, and adding hydrochloric acid to the clear filtrate. The precipitated sulphur is very finely divided, white, and completely soluble in carbon disulphide. This form is used in medicine as a laxative, antiseptic, and antiparasitic in dusting powders and ointments. The other solid form, amorphous or plastic sulphur, is formed by sudden cooling of the molten material as by pouring into cold water. It is dark-red or brown in color, rubberlike, specific gravity 2.046, and insoluble in carbon disulphide. On standing, it becomes brittle, yellow, and partly soluble in carbon disulphide as it reverts to the rhombic form. In addition to these crystalline and amorphous forms, there is an intermediate form, known commercially as flowers of sulphur or sublimed sulphur, produced by chilling sulphur vapor without passing through the liquid phase. It is composed of small grains with a crystalline center and amorphous surface. It is slowly and incompletely soluble in carbon disulphide. When treated with ammonia, to remove such impurities as arsenic, the product is known in medical circles as washed sulphur, the uses of which are similar to those of the colloidal form.

**Uses and Principal Compounds.** Nearly half of the sulphur consumed is used in making important chemical compounds like sulphuric acid, sulphur dioxide, and carbon disulphide. Other important uses are in insecticides, fertilizers, and explosives; the manufacture of paper, plastics, paint, and dyes; and the vulcanizing of rubber.

*Sulphur Dioxide.* The compounds of sulphur are many and important. There are two important oxides, the dioxide, $SO_2$, and the trioxide, $SO_3$. The dioxide is produced by burning sulphur in air; and vast quantities of it result from the roasting of sulphide ores of the metals. Sulphur dioxide, a colorless gas with a suffocating odor, is readily soluble in water, forming sulphurous acid. It is easily liquefied (boiling point —10° C.) and is sold in steel cylinders. It is used in the manufacture of sulphuric acid; in household refrigerating units; in bleaching, as in textiles, straw, wood pulp, beet sugar, in preserving fruits and vegetables; and in disinfecting, as in breweries, food-processing plants, starch factories.

*Sulphurous Acid.* Sulphurous acid, $H_2SO_3$, is a clear, colorless liquid that contains about 6 per cent sulphur dioxide. It is a weak acid (ionization constant $5 \times 10^{-6}$, giving $2H^+$), forming both sulphites and acid sulphites. It is a good reduc-

ing agent, uniting with oxygen to give sulphuric acid. It is used for removing the coloring matter from silk, wool, straw, paper, and similar materials. It is used also as an antiseptic and preservative, especially for preventing the growth of fungus in wine casks and preventing fermentation when corn is being softened for the extraction of starch. It is also used in preserving foods to prevent blackening and fermentation. The most important salt of sulphurous acid is calcium acid sulphite, $Ca(HSO_3)_2$, used for the digestion of wood chips in the preparation of wood pulp.

*Sulphur Trioxide.* Sulphur trioxide, $SO_3$, the anhydride of sulphuric acid, is obtained either as a colorless liquid or as a white crystalline solid. It is formed by oxidation of sulphur dioxide by means of oxygen in the presence of a suitable catalyst (platinum, vanadium pentoxide). It fumes strongly in moist air and dissolves in water, forming sulphuric acid and liberating a large amount of heat. It is used in making sulphuric acid and in the production of synthetic organic compounds.

*Sulphuric Acid.* Sulphuric acid, $H_2SO_4$, is made by steps which appear to be relatively simple but actually are highly involved. Sulphur is oxidized to sulphur dioxide by burning in air or by roasting sulphide ores. This product is further oxidized to sulphur trioxide either by the use of a catalyst (contact process) or by the use of the oxides of nitrogen (lead-chamber process). The refined acid is a heavy, colorless liquid called oil of vitriol, which fumes in moist air and absorbs water vigorously, even decomposing many carbohydrates like sugar ($C_{12}H_{22}O_{11}$) which contain hydrogen and oxygen in the same proportion as they are found in water. Sulphuric acid is highly corrosive and produces severe burns upon the skin. It is readily dissociated by heat, yielding sulphur trioxide and water. It reacts with many of the metals and metallic compounds. Because it is an active acid and not expensive, its uses are very numerous.

Fuming sulphuric acid is the concentrate acid to which an excess of sulphur trioxide has been added. It is a colorless, or brownish, oily liquid, known commercially as oleum; it gives off offensive fumes of sulphur trioxide and is an extremely active chemical reagent.

*Thiosulphuric Acid.* Thiosulphuric acid, $H_2S_2O_3$, is sulphuric acid in which one atom of oxygen has been replaced by sulphur. Its most important derivative is sodium thiosulphate, $Na_2S_2O_3 \cdot 5H_2O$, colorless crystals formed when sodium sulphite, $Na_2SO_3$, is boiled with flowers of sulphur. It is used in photography as a fixing agent and is known as the hyposulphite of sodium or simply as hypo. It is also used in the bleaching industry as an antichlor to arrest the action of chlorine before the fibers are weakened by too long exposure to chlorine; in dyeing and printing textiles; in extracting silver from its ores; in tanning leather; and in bleaching bone, straw, and ivory.

*Other Oxyacids.* There are many other oxyacids of sulphur, more or less closely related to sulphurous or sulphuric acids. Perhaps the most interesting of these is sulphamic acid, $HSO_3 \cdot NH_2$. It should be regarded as sulphurous acid, with one of its hydrogens replaced by the amino group, $NH_2$. Sulphamic acid is prepared by the action of oleum on urea, $NH_2 \cdot CO \cdot NH_2$. This strong acid forms colorless crystals, stable in dry air, soluble in water, and hydrolyzed in solution. Its most useful compound is ammonium sulphamate, a white crystalline powder readily soluble in water. It is useful in making textiles, paper, and wood fire-resistant. As a weed killer, it is particularly effective against poison ivy.

*Sulphonal.* Sulphonal, $(CH_3)_2 \cdot C \cdot (SO_2 \cdot C_2H_5)_2$, is a white, odorless crystalline drug, slightly soluble, used as a sedative and hypnotic in cases of insomnia, alcoholism, nervous afflictions, and insanity.

*Hydrogen Sulphide.* Hydrogen sulphide, $H_2S$, called also sulphuretted hydrogen and hydrosulphuric acid, is a colorless gas with an offensive odor suggestive of rotten eggs. It is a little heavier than air (sp. gr. 1.189), easily condensed to a colorless liquid (b.p. —61.8°C.), and readily soluble in water. The liquid is a useful solvent. The solution, or the gas, itself, is used extensively in qualitative analysis in the detection and separation of many of the metals. When inhaled in a small amount, the gas produces headache and nausea; a larger amount or continued inhalation produces paralysis, especially of the nerves, heart, and lungs. The paralysis gives no warning of its approach, and serious injuries may result from a fall caused by the suspension of vital body functions. The water solution of the gas is a weak acid, with a *p*H of approximately 4; the apparent ionization constant, giving $2H^+$, is $1.2 \times 10^{-15}$. The formula of hydrogen sulphide suggests a close relationship to water; but perhaps nothing shows more clearly the contrasts between sulphur and oxygen than a comparison between $H_2S$ and $H_2O$. In hydrogen sulphide, sulphur acts as a typical nonmetal, the valence of sulphur in this compound being —2; but the behavior of these two compounds shows almost no other point of similarity, and their contrasts are striking.

*Sulphur Monochloride.* Sulphur monochloride, $S_2Cl_2$, is a fuming, oily liquid with an amber color and penetrating odor, causing tears and labored breathing. It fumes in moist air and is decomposed by water, but is soluble in carbon disulphide. Sulphur monochloride is a good solvent for sulphur, iodine, metallic halides, and organic compounds. It is used in vulcanizing rubber, and in making printing inks and insecticides. When it reacts with ethylene, sulphur monochloride produces a volatile liquid known as mustard gas, $(C_2H_4)_2Cl_2S$, a highly irritating and toxic substance used in chemical warfare.

*Carbon Disulphide.* Carbon disulphide, $CS_2$, is a faintly yellow liquid, highly inflammable and poisonous. It is made by the direct union of the elements in an electric furnace. It does not mix with water and has a high index of refraction, high vapor tension, and low boiling point, 46° C. It is an effective solvent for fats, oils, rubber, and resins. It is widely used in the extraction of oils, in the manufacture of viscose rayon, varnishes, rubber cements, and matches, for destroying weevils and clothing moths, and for disinfecting soils. *See also* SULPHURIC ACID. B. S. H.

**SULPHUR FLOWER,** a white wooly perennial, *Eriogonum umbellatum,* of the buckwheat family, having a branching, woody base surrounded by many small leaves. Several long-stalked umbels of brilliant, drooping flowers, sulphur-yellow in color, are borne at the summit of the naked flower stalks, which are 4 to 12 in. high. The plant is native to dry elevated valleys and mountains from California and Washington to Colorado and Wyoming; it grows usually at an altitude of 4,000 to 9,000 ft. J. C. Wis.

**SULPHURIC ACID** [sʌlfyu'rɪk], the mineral acid $H_2SO_4$, is generally classed as the most important of the acids. It appears to have been known as far back as the ninth century. In the thirteenth century, sulphuric acid was referred to by Albertus Magnus as spirit of vitriol. It has likewise been termed oil of vitriol and vitriolic acid because of its appearances and its derivation from green vitriol (ferrous sulphate). Although its preparation was described as early as the fifteenth century, the exact composition of

sulphuric acid was not known until the time of the French scientist Antoine Laurent Lavoisier (1743-1794). The salts of sulphuric acid are widespread over the earth's surface; for example, gypsum (the dihydrate of calcium sulphate), and the many brine deposits containing sulphates of the alkaline and alkaline-earth metals. Sulphuric acid, itself, may be found in the vicinity of volcanoes, where it results from the oxidation in moist air of the sulphurous gases emitted.

Time has contributed much to the technology of the manufacture of sulphuric acid. The equipment designed for its production introduced new concepts and principles, which have since been applied in other similar manufacturing processes.

## LEAD-CHAMBER PROCESS

The oldest method of manufacturing sulphuric acid is the lead-chamber process, introduced in 1746 at Birmingham, England. Although this process owes its name to the characteristic large reaction chambers made of sheet lead, the entire modern plant usually consists of sulphur dioxide-producing burners, a niter pot or ammonia oxidation unit, a Glover tower (introduced in 1858), the chambers proper, and the Gay-Lussac tower (introduced in 1830). The over-all reaction, which consists in oxidizing sulphurous gas to sulphuric acid, is promoted by nitrogen oxides formed either by the action of process acid on Chile saltpeter or by the oxidation of ammonia. These reactions yield the nitric oxides, NO and $NO_2$. By a series of intermediate reactions not yet fully understood, the nitric oxides react with sulphur dioxide and air in the presence of moisture to form nitrosyl sulphuric acid according to the following reaction:

$$\underset{\text{Sulphur dioxide}}{2SO_2} + \underset{\text{Oxygen}}{O_2} + \underset{\text{Nitric oxide}}{NO} + \underset{\text{Nitrogen dioxide}}{NO_2} + \underset{\text{Water}}{H_2O} = \underset{\text{Nitrosyl sulphuric acid}}{2NO \cdot HSO_4}.$$

In the presence of excess water, the nitrosyl sulphuric acid decomposes to sulphuric acid and nitrogen trioxide:

$$\underset{\text{Nitrosyl sulphuric acid}}{2NO \cdot HSO_4} + \underset{\text{Water}}{H_2O} = \underset{\text{Sulphuric acid}}{2H_2SO_4} + \underset{\text{Nitric oxide}}{NO} + \underset{\text{Nitrogen dioxide}}{NO_2}.$$

**Sulphur Burners.** The first step in the production of sulphuric acid is the manufacture of sulphur dioxide. One important source of sulphur for this process is a yellow ore, consisting essentially of the sulphide of iron, and known as fool's gold or, more commonly, pyrite. Pyrite burns in air to form sulphur dioxide and iron oxide, which may be used as iron ore. The pyrites may be burned in lump form in ordinary furnaces, or as fines. Fines are spread over a series of plates in a multiple-hearth furnace, which may be either stationary or equipped with rotary scrappers. Once combustion has been initiated by a coke fire, for example, the pyrites themselves will support combustion in the presence of a positive air flow over the plates. Very finely divided pyrites are burned in powder form by injection with air into a flash burner. Sulphides of copper and zinc (blende) also are sources of sulphur. For this reason, sulphuric-acid plants are sometimes located near smelters, which use the sulphurous gases discharged by the pyrite and blende roasters. The third important source of sulphur in the production of sulphuric acid is brimstone sulphur. Sulphur may be burned in the tray-type furnaces, but a more satisfactory method consists of spraying molten sulphur with air into a special burner.

**Nitrogen Oxides Unit.** The sulphur dioxide gases pass from the burners to the source of nitrogen oxides. Where these are formed by the action of process acid on Chile saltpeter, the gases pass over the niter pot, yielding heat, which promotes the reaction forming nitric acid. When oxidation of ammonia is used to produce the nitrogen oxides, the gases pass separately to the Glover tower.

**Glover Tower.** A Glover tower is essentially a tall structure lined with sheet lead and acidproof brick. It is filled with quartz of assorted sizes in such a way that spaces are left at the bottom and the top of the tower for distribution and drawoff of gases and acids. The burner gases enter at the bottom of the tower and rise through the stream of Gay-Lussac and chamber acid which is sprayed over the quartz filling by means of a suitable distributor at the top of the tower. This simple design fulfills four important functions: (1) it cools the sulphurous gases from the burners prior to their entrance into the lead chambers; (2) it utilizes the heat absorbed to concentrate chamber acid; (3) it recovers the nitrogen oxides released from the Gay-Lussac acid by the dilute chamber acid; (4) it supports the preliminary reaction between the steam, nitrogen oxides, and sulphur dioxide in the formation of the sulphuric acid. Glover acid issuing from the bottom of the tower is further cooled and pumped to the top of the Gay-Lussac tower for recovery of nitrogen oxides by absorption.

**Lead Chambers.** The initial reaction products, on the other hand, pass from the top of the tower to a series of rectangular lead chambers, where the reaction is completed by the injection of steam or, preferably, atomized water at the inlet pipe. The vigorous reaction, which proceeds according to the second of the equations given, produces a heavy mist of sulphuric acid, which slowly settles. The unreacted gases, together with the nitrogen oxides released, pass to the succeeding chamber. In the reaction chambers the concentration of the reactants is so regulated that 55° Bé acid forms. This is drawn off from the chamber floor and shipped, or returned to the Glover tower for concentration to 60° Bé.

Actually, a small percentage of the total acid formed in the chamber process is produced in the Glover tower. Observation that the cooler portions of this tower and of the lead chambers are particularly favorable for the formation of acid resulted in the chamber process being subjected to modifications. These, in their extreme form, eliminate entirely the air-cooled lead chambers. For example, the Anaconda packed cell towers comprise acid-cooled towers packed with acidproof brick. In the Mills-Packard chambers, characterized by a truncated-cone shape, the chamber reaction is promoted by water cooling; water flows over the exterior of the towers.

**Gay-Lussac Tower.** Gases from the reaction chambers pass to the Gay-Lussac tower, the purpose of which is to recover the major portion of the nitrogen oxides. Constructed of lead-lined steel or acidproof brick, the Gay-Lussac tower is packed with graduated lumps of quartz or acid-resisting stoneware. The size of the packing material decreases with the height in the tower, as is the custom where it is desired that more intimate contact be obtained between absorbent and the substance being absorbed, as the latter decreases in concentration. Cold Glover acid, introduced at the top, is the absorbent which is used for recovering the rising nitrogen oxide gases.

**Concentrating the Acid.** Chamber acid may be concentrated to a maximum strength of 66° Bé. by evaporation, as in a series of pans set stepwise over a suitable source of heat, or by injection of hot gases to remove water. It is also possible to pass the gas in countercurrent to hot gases down a tower packed with quartz. Concentration above 66° Bé. is not possible, however, because the acid has a tendency to decompose on continued evaporation.

Basically the formation of sulphuric acid is brought about by three reactions:

$$\underset{\text{Sulphur}}{S} + \underset{\text{Oxygen}}{O_2} = \underset{\text{Sulphur dioxide}}{SO_2} \quad (1)$$

$$\underset{\text{Sulphur dioxide}}{SO_2} + \tfrac{1}{2}\underset{\text{Oxygen}}{O_2} = \underset{\text{Sulphur trioxide}}{SO_3} \quad (2)$$

$$\underset{\text{Sulphur trioxide}}{SO_3} + \underset{\text{Water}}{H_2O} = \underset{\text{Sulphuric acid}}{H_2SO_4} \quad (3)$$

The second reaction is the difficult one. Essentially, it is realized in the chamber process by nitric oxides through the intermediate formation of nitrosyl sulphuric acid.

## CONTACT PROCESS

The contact process, introduced in Germany in 1901, effects the oxidation of sulphur dioxide to sulphur trioxide with the aid of a solid catalyst. As is typical of such catalytic processes, a relatively large surface of contact material is required, by comparison with the total quantity of catalyst present in the reaction chamber. For this reason, it is the practice to use a catalyst in suitable form for extension over a large area of inert substance, such as asbestos, silica gel, or magnesium sulphate. Three catalysts in particular have been used for the contact process of manufacturing sulphuric acid: iron oxide, platinum, and vanadium compounds of the vanadium pentoxide class, to list them in their order of increasing importance.

**Reaction Conditions.** Sulphur dioxide oxidizes to sulphur trioxide with evolution of heat—45,200 cal. At the same time, the reaction is a reversible one, favored by the presence of an excess of oxygen. As much as 150 to 200 per cent of oxygen over the amount called for by the reaction equation is used. While the rate of formation of sulphur trioxide is accelerated by temperatures above 400° C., the reverse reaction is likewise favored at higher temperatures, with the result that an optimum temperature between 400 and 500° C. is usually maintained. In a refinement of this technique, some plants even promote the formation of sulphur dioxide by carrying out the initial phase of the reaction at temperatures of 500° C., and over. As conversion nears completion, the gases are cooled to impede decomposition of the sulphur trioxide formed. In the contact process, this conversion of sulphur dioxide to sulphur trioxide may reach from 96 to 97 per cent.

**Catalysts and Poisons.** As in the great majority of catalytic reactions, one of the chief problems in the contact process is the protection of the catalyst from poisoning by impurities in the sulphur dioxide gases. For this reason, in the past, over 50 per cent of the sulphur dioxide produced in the manufacture of contact acid has been made from brimstone. From the standpoint of economic utilization of national resources, however, such practice is considered extravagant, and pyrites are gradually being adopted as sources of sulphur—suitable provisions being taken for the effective removal of catalyst-toxic impurities from the sulphurous gases produced. Dust, moisture, arsenic, and the halogens are among the worst offenders as catalyst poisons. The hot, dust-laden, sulphurous gases therefore pass from the burners into chambers, where baffles cause the precipitation of the dust particles. Cyclone- and electrostatic-type dust collectors may also be installed in the circuit. The gases, freed of dust, then pass to scrubbers, constructed of lead in a manner similar to the Glover towers. In these, a downward flow of acid removes the other impurities: dilute acid is required to eliminate the halogens and arsenic; concentrated acid, moisture and any traces of metal present.

**Heat Exchangers.** To bring the purified gases up to the optimum reaction temperatures, a series of heat exchangers is used. Heat exchangers are essentially enclosed pipes through which flow in countercurrent the cold and hot gases. Thus, the cold gases may pass to the interior of a heat exchanger where they circulate around pipes through which the hot, spent reaction gases flow. The cold gases are thereby preheated and pass to the converter. The converter may be described as an enclosed unit packed with catalyst, or in which the catalyst is distributed on trays, facilitating contact with the rising gases. When the conversion is effected in two phases, first at higher and then at lower temperatures, the reaction gases may pass from the converter to the heat exchanger or preheater, where they not only heat the incoming gases but also complete their reaction.

**Absorption of Sulphur Trioxide.** The reaction gases finally pass to absorption towers packed with stoneware, over which falls a rain of concentrated acid. It is necessary to absorb sulphur trioxide in concentrated acid because of its high heat of solution in dilute acid or water. Even with the use of concentrated acid as absorbent, cooling of the issuing acid is necessary. Gases which escape absorption in the first tower may be passed to successive absorption towers to form acids of lower concentrations.

## COMMERCIAL ACIDS

It is possible, for example, to produce acids of 93 to 98 per cent content, 20 per cent oleum, and even 40 per cent oleum by the contact process. Oleum is a solution of sulphur trioxide in sulphuric acid; it is also known as fuming sulphuric acid. Equimolecular proportions of sulphur trioxide and sulphuric acid combine to form pyrosulphuric acid, $H_2S_2O_7$, a solid crystalline compound.

Pure sulphuric acid (hydrogen sulphate) dissociates to sulphur trioxide and water when heated above 100° C., until a constant-boiling mixture containing 98.33 per cent sulphuric acid is obtained. The mixture boils at 338°C. (640° F.).

When concentrated sulphuric acid is diluted with water, there is considerable evolution of heat. Safe practice dictates that such dilutions be made by adding the sulphuric acid to water (not water to acid), with constant stirring.

## CHEMICAL BEHAVIOR AND USES

The normal acid action of sulphuric acid on metals depends upon its concentration. In dilute solutions, metals preceding hydrogen in the electromotive series are attacked by sulphuric acid with formation of the metal sulphate and liberation of hydrogen. Concentrated solutions of sulphuric acid, however, attack many metals, regardless of their position in the electromotive series, to give the metal sulphate and water, with liberation of sulphur dioxide formed during an intermediate oxidation of the metal by sulphuric acid.

Sulphuric acid owes its extensive use largely to three important properties: (1) it is hygroscopic; (2) it is a strong acid; and (3) it is a powerful oxidizing agent.

The avidity of sulphuric acid for water is utilized in industry in the concentration of nitric acid and in nitration reactions. Moisture is removed from gases in towers using sulphuric acid as scrubber.

The action of dilute sulphuric acid on metals is applied in the metal-finishing trades for pickling metal surfaces prior to plating and other finishing treatments. The property possessed by sulphuric acid of displacing lower-boiling acids

from their salts is utilized in the manufacture of these acids. The most important application, however, is its use in the conversion of insoluble phosphate rock to soluble calcium phosphates for use as fertilizers. Approximately one third of the sulphuric acid consumed in the United States goes to the fertilizer industry.

Concentrated sulphuric acid, as an oxidizing agent, chars most organic substances, such as sugar, wood, and cotton. This property has been used in the petroleum industry in the purification of various fractionation products by agitation with 66° Bé. acid, followed by water washing and neutralization with dilute caustic soda. In the dyestuff industry, sulphuric acid serves largely as a sulphonating agent.

Electrolysis of dilute solutions of sulphuric acid liberates hydrogen at the cathode and forms persulphuric acid, $H_2S_2O_8$, at the anode. On hydrolysis, the persulphuric acid is decomposed to hydrogen peroxide and sulphuric acid, which returns to the electrolytic cells.

A common use of sulphuric acid is made in the electrolyte of the lead-cell storage battery. *See also* Storage Battery, Electrical; Sulphur. J. Se.

**SULPHUR SPRINGS,** a city in northeastern Texas, the county seat of Hopkins Co., located 85 mi. northeast of Dallas. It is served by the St. Louis Southwestern and the Louisiana & Arkansas railroads. Cotton, grain, fruit, and truck crops are the chief agricultural products of the region. The city has a cottonseed-oil mill, a meat-packing plant, and cheese and canning factories. Pop. 1950, 8,991.

**SUL PONTICELLO.** *See* Musical Terms.
**SUL TASTO.** *See* Musical Terms.
**SULUBBA.** *See* Asiatic Tribes (*Semitic*).

**SULU SEA** [su'lu], a relatively shallow, island-and-reef-studded, tropical body of water, lying between the Philippine Islands and Borneo. It is enclosed by the island of Palawan on the west and northwest, Mindoro and Panay islands on the north and northeast, Mindanao Island on the east, and the Sulu Archipelago and Borneo on the southeast and south. The Sulu Sea connects to the southward with the Celebes Sea, eastward with the Mindanao Sea and the Pacific Ocean, northeastward with the Visayan Sea, and northward and westward with the South China Sea. Its greatest depth is 15,900 ft. The Sulu Sea was the scene of a battle between the United States and Japanese naval and air forces during World War II. R. G. B.

**SUMAC** [shu'mæk; syu'mæk; su'mæk], common name of a large genus, *Rhus,* of trees and shrubs of the cashew family, native chiefly to subtropical and warm temperate regions. They are shrubs or medium-sized trees, having leaves usually pinnate, and greenish or whitish flowers, often in dense terminal panicles. The one-seeded fruits are dry and small, often a showy red. The tan sumac, *R. coriaria,* of southern Europe, is grown for its leaves and for its bark, which is used in tanning and dyeing. Common throughout much of eastern North America are the smooth sumac, *R. glabra,* and the staghorn sumac, *R. typhina,* both large shrubs which are planted for ornament, in different varieties, because of their brilliant fall color. The shining sumac, *R. copallina,* a shrub or small tree of eastern North America having glossy foliage which turns red in autumn, is also used as an ornamental. Among the sumacs of the Pacific states are the laurel sumac, *R. laurina;* the sugar bush, *R. ovata;* and the lemonade berry, *R. intergrifolia,* all attractive shrubs having evergreen leaves.

A group of poisonous plants, *Toxicodendron,* is sometimes included with the sumacs. Important economically is the lacquer tree of eastern Asia, *T. verniciflua,* the source of Japan lacquer, and the Japanese wax tree, *T. succedaneum,* the crushed berries of which are a source of wax. The poisonous species native to North America are called poison ivy, poison oak, and poison sumac. *See also* Fustic; Poison Ivy. J. C. Wis.

**SUMATRA** [sumɑ'trə], the westernmost large island of the Malay Archipelago, in the Republic of Indonesia. It has a northwest-southeast axis and is almost exactly bisected by the equator. The Strait of Malacca separates it from Malaya to the northeast and Soenda Strait from Java to the southeast; the southwestern coast faces the Indian Ocean. Sixth largest of the world's islands, Sumatra has an area of approximately 167,500 sq. mi.; its greatest length is 1,060 mi. and its greatest width, 248 mi.

**Topography.** Less developed and as a whole less fertile than Java, Sumatra along its southwestern side is a series of parallel mountain ranges collectively known as the Barisan Mountains (Bukit Barisan), which are interspersed with 12 active and 78 inactive volcanoes as well as with fertile tuff plateaus. The highest peak is Mount Kerintj (12,467 ft.). The eastern coast, a vast swampy lowland, is crossed by wide meandering rivers, such as the Kampar, Inderagiri, and Moesi, and is covered by thick forests and dotted with many rubber plantations. The area is rich in petroleum; the Palembang area has coal and lignite. The soil of Sumatra is agriculturally useless except at the southeastern (Lampong) and northeastern (Medan) extremities. The flora and fauna of the island are similar to those of Java.

**Climate.** The climate is primarily equatorial with most of the rain coming in those regions where the regular monsoons have been broken up by the lofty Barisan Mountains. In the extreme north and south the monsoonal climate, with one relatively drier season, occurs. Rainfall varies between less than 60 in. in the Toba Lake region to over 200 in. in the Lebong area. The highest temperatures are registered during the relatively drier seasons, but the average monthly difference is never greater than 2° F. On the lowland plains the temperature ranges between 70° and 88° F.

**Ethnology and Population.** In 1950 the population of Sumatra was estimated at 11,000,000. In the ethnic composition of the people, Veddoid traces of pre-Malayan inhabitants are still to be found in the inaccessible forests of the eastern plain. The interior highlands as well as the western islands reveal indications of other ancient races, such as the Caucasian and the Niasese (200,000), the latter, it is believed, being remotely related to the Maoris and Tahitians of the Pacific, whereas the proto-Malay Bataks (1,600,000) of the Toba Lake region abound in Dravidian and Melanesian types. The Malays (4,000,000) are in the majority practically everywhere. Originally coming from Asia to settle in central Sumatra, they later spread from this center, particularly into eastern Sumatra. The highland Minangkabau (2,700,000), a matriarchal society, observe the highest elements of their original culture. The Redjang-Lampong (1,000,000) of the southern tip of the island apparently once belonged to the Batak but were separated from them when later Malays drove a wedge between. Hindu and Hindu-Javanese culture and Sudanese blood from Java have deeply affected this ethnic group. The Achinese (1,200,000) of the northwestern coastal strip are a Malay-Indo-Arabian amalgam and show a clear Semitic strain. The coastal Malays, last comers of them all, occupy all the remaining parts of Sumatra, except for some highland regions which are

BOB LANDBACH FROM BLACK STAR

*Carabao are worked as beasts of burden on the island of Sumatra.*

inhabited by many other small tribes such as the Lebong, Kurinchi, Gajos, and Alas. Besides these there were approximately 1,000,000 Javanese and Sudanese, 400,000 Chinese and other Asiatics, chiefly Arabians, and a few thousand Europeans. The largest cities on the island are Palembang (150,000), Medan (125,000), and Padang (60,000).

The population is predominantly Mohammedan, except for the peoples living on the small islands to the west and two-thirds of the Bataks. One half of this group of Bataks is Christian; the remainder still adheres to animistic beliefs.

**Economic Activities.** Irrigated and nonirrigated rice and maize, especially in the Batik highlands, are the chief subsistence crops, whereas rubber, pepper, copra, coffee, tobacco, cotton, kapok, cloves, nutmeg, gambier, tea, oil palms, sisal, cinchona, cocoa, and ground and beetle nuts are grown, mainly for export, in northeastern Sumatra and in the highlands of Tapanuli and Padang. Gutta percha, various resins, gums, valuable timber, and birds' nests for Chinese consumption also form part of the domestic consumption. Pigs are kept only by non-Mohammedans, and there are few cattle. Fishing, both fresh and salt water, forms an important part of the economy.

Coal is mined in the Padang highlands and near Palembang. Oil is found along the eastern plain from Achin to Palembang. Gold and silver are mined in the vicinity of Benkoelen. E. J. C. K. de J.

**History.** Sumatra was one of the first islands of the Malay Archipelago to be settled by Hindu immigrants, and by the seventh century the powerful kingdom of Srividjaya, with its capital near the present city of Palembang, had been established in eastern Sumatra. Ruled by the Shailendras dynasty, the kingdom was for many centuries the mightiest maritime power in the archipelago, extending its influence over the greater part of Sumatra, Java, and peninsular Malacca, and controlling the strategic Strait of Malacca. Its prosperity lasted until the end of the thirteenth century, when the Javanese kingdom of Modjopahit established hegemony. Javanese colonists then penetrated the former kingdom, while at about the same time the Arabs first invaded northern Sumatra (Achin). Marco Polo, who visited the island in 1291, first reported the Mohammedan penetration; in the early part of the sixteenth century the Portuguese established trading relations with the rulers of Achin, who were then becoming increasingly powerful. The sultanate reached its height in the reign (1607-1636) of Sultan Iskandar Muda, when it controlled the greater part of the island.

The English first visited Achin in 1602, and in 1663 the Dutch established settlements on the west coast. In the time of the United East Indies Company (1602-1800) Sumatra's role in colonial policy was slight, except for almost continuous commercial rivalry with the British, who had also established settlements near Benkoelen. In 1819 the British concluded a treaty with the Achinese whereby other European powers were to be excluded from the kingdom, but in 1824 they handed over their rights in Sumatra to the Dutch in exchange for Malacca. Gradually the several lesser kingdoms on the island were subdued, but Achin was not suppressed until 1900, after a war lasting thirty years and costing some 250,000 lives. The Dutch, however, were never able to secure effective control of more than the coastal area.

During World War II, from 1942 to 1945, Sumatra was occupied by Japan. Following the defeat of the Japanese, the island came under the authority of the newly created Republic of Indonesia, and with the formation of the United States of Indonesia, in December 1949, its several states became a part of the new federation. With the end of the federation in 1950, when all the separate states ceased to exist and became a part of the Republic of Indonesia, Sumatra was divided into three provinces (North, Central, and South Sumatra), under which are eleven residencies. Each province is administered by a governor responsible to the central government at Jakarta, the capital of the republic. C. W. D.

**SUMBA.** *See* SOEMBA.

**SUMBAWA.** *See* SOEMBAWA.

**SUMERIAN** [sumɪ′ərɪən], a language spoken in Babylonia at the time when cuneiform writing developed from primitive picture-writing into a standardized script. To judge from the evidence of place names, it was spoken over most of Mesopotamia during the fourth millennium B.C., especially by the settled population. Its old rival, Accadian, or Semitic Babylonian, gained the upper hand about 2400 B.C., and Sumerian became extinct as a spoken tongue soon after 2000 B.C. It survived, however, as a learned language to about the Christian Era, if not even later.

Sumerian was identified as a separate language by Assyriologists soon after the decipherment of the cuneiform script. After about fifty years of slow progress, its interpretation has advanced steadily since 1900. Today, thanks particularly to the work of F. Thureau-Dangin, Arno Poebel, and the latter's pupil, S. N. Kramer, Sumerian can be read with little difficulty, though there are still unknown words and obscure passages. The language shows no family relationship to any other known language, ancient or modern; at the dawn of history it had already broken down phonetically to such an extent that many originally distinct words had fallen together in pronunciation. Such words seem to have been distinguished by the use of different accents or tones, much as in Chinese. Structurally, Sumerian shows a strong agglutinative tendency to incorporate nonverbal elements into a verbal complex, as in Turkish. Since Sumerian was the dominant language in what was perhaps the earliest culture of the Old World, it is not surprising that it strongly influenced the Semitic languages which successively followed it as vehicles of higher culture. Accadian, Aramaic, Arabic, and Hebrew

contain many words of Sumerian origin, generally relating to the arts and crafts. W. F. A.

**SUMERIANS** [sumɪ′əriənz], first civilized inhabitants of ancient Babylonia (modern Iraq). Perhaps as early as 5000 B.C. the Sumerians came from the east or descended from the mountains of Elam to the swampy plain (ancient Sumer) at the head of the Persian Gulf. They drained the swamps, instituted flood control, and established agriculture on a permanent basis. With the development of trade with surrounding areas—Iran, Elam, Assyria, India, and the Mediterranean coast—the Sumerian settlements grew into prosperous city states which by 3500 B.C. possessed a mature civilization characterized by urban life, metal working, textile manufacture, monumental architecture, and an efficient system of writing.

The Sumerian states were theocratic; each state was considered the property of a particular local god who was represented on earth by a high priest (*patesi*) who was the religious and governmental head of his community and its surrounding territory. Geographic areas of great importance in this early period were the cities of Ur, Erech, Umma, Eridu, Lagash, Nippur, Sippar, and Akkad, a Semitic state in the north. Interstate wars were common, and sometimes brief local empires were established when one state would conquer a few of its neighbors. About the middle of the third millennium B.C., however, Semitic tribes from the Arabian Peninsula, who had settled in northern Babylonia and adopted Sumerian culture, became strong enough to endanger Sumerian independence. Sargon of Akkad, about 2650 B.C., conquered the Sumerians and carved out an empire which stretched from the Persian Gulf to the Mediterranean Sea. After perhaps 2500 B.C., however, the Akkadian power declined, and a new period of independence and prosperity began for the Sumerians; this is the era of the Third Dynasty of Ur and the greatness of Lagash under Gudea. The end came about 2000 B.C. with the rise of the Amorite kingdom, a new Semitic state with its capital at Babylon; the Sumerians lost their independence forever, and the old areas of Sumer and Akkad were swallowed up by the empire of Hammurabi.

Although the Sumerians disappeared as a people and their language ceased to be spoken in Babylonia, their system of writing (cuneiform) and many elements of their religion still formed an integral part of Babylonian, and, later, Assyrian, culture. They had laid the foundations for the civilization of a large part of the Near East, and the business organization, technology, and scientific knowledge which they bequeathed to their successors was very important. *See also* BABYLONIAN AND ASSYRIAN ART. T. B. J.

**SUMMER.** *See* SEASONS.

**SUMMER CYPRESS,** also called mock cypress and burning bush, a bushy annual plant which grows about 5 ft. high. A member of the genus *Kochia* of the goosefoot family, it has narrow leaves which turn deep red in autumn. J. C. Wis.

**SUMMER FLOUNDER.** *See* FLUKE, OR SUMMER FLOUNDER.

**SUMMERSIDE,** a port town in Prince Co., Prince Edward Island, Canada, situated on Bedeque Bay, 36 mi. west of Charlottetown and 124 mi. north of Halifax, Nova Scotia. It is served by the Canadian National Railways, which maintains a ferry service from near-by Port Borden to Cape Tormentine on the mainland of New Brunswick. Potatoes, dairy products, silver fox furs, and the celebrated Malpeque oysters are products of the region. Summerside is a tourist resort, a trading center, and a farmer's supply point for the western end of the island. It was incorporated in 1903. Pop. 1951, 6,547. D. F. P.

**SUMMIT,** a village in northeastern Illinois, situated in Cook Co., at the crest of the watershed between the Mississippi and the Great Lakes, on the Illinois and Michigan Canal. Summit lies 10 mi. southwest of the heart of Chicago, of which it is an important suburb. Limestone is a natural resource of the region. The local government is the mayor-councilmanic type. Summit was incorporated as a village about 1890. Transportation is provided by the Gulf, Mobile and Ohio Railroad. The city is the site of one of the largest corn refineries in the world. Besides corn products, its industries produce chemicals and paints. Pop. 1950, 8,957.

**SUMMIT,** a residential city in northeastern New Jersey, situated in Union Co., on the crest of one of a series of hills popularly known as First Watchung Mountain, near the Passaic River, 10 mi. southwest of Newark, and 19 mi. southwest of New York City. The surrounding area is devoted to general farming. Founded about 1795, Summit was incorporated as a city in 1899. A mayor and city council govern the city. Strategically important in relation to western New Jersey during the Revolutionary War, the ridge of First Watchung Mountain was a vital observation post from which General Washington's lookout men would warn of any approaching British raiders. A marker commemorates the site of a small cannon which was used as a warning gun. Transportation is furnished by the Delaware, Lackawanna and Western, and the Rahway Valley railroads. Local factories manufacture chemicals, silk, aprons, and knit goods. Pop. 1950, 17,929.

**SUMMIT HILL,** a borough in Carbon Co., in eastern Pennsylvania, 27 mi. northwest of Allentown. It is served by the Lehigh and New England Railroad for freight transportation. Anthracite was discovered in the valley in 1776, and the deposits proved so extensive that coal mining continues as the sole industry of the region. The famous Burning Mine in the vicinity was on fire for more than a century. Summit Hill's Mauch Chunk Switch-Back railway, now abandoned but which had its first run in 1827, was one of the first railroads to be built in the United States. Summit Hill was incorporated in 1889. Pop. 1950, 4,924.

**SUMMONS.** *See* LEGAL PROCEDURE.

**SUMNER, CHARLES** (1811-1874), United States senator, was born in Boston, Mass., Jan. 6, 1811. He was educated at Harvard University, received his law degree in 1833, and was admitted to the bar in 1834. A good orator, he made many speeches attacking slavery, and spoke in opposition to the annexation of Texas in 1845 and against participation in the War with Mexico. He helped to organize the Free Soil Party in 1848 and in 1851 was elected to the United States Senate from Massachusetts. His caustic speeches attacking slavery prompted Representative Preston Brooks of South Carolina to attack Sumner bodily in 1856; Sumner never fully recovered from the injuries he received at that time. After Lincoln's election to the presidency in 1860 Sumner was a principal champion of the abolitionist cause in Congress. In 1861 he helped to achieve a peaceful

settlement of the international dispute arising from the Federal seizure of Confederate agents from a British ship during the American Civil War. Sumner was a strong advocate of Congressional superiority and felt that Congress, rather than the President, should be responsible for the reconstruction of the South after the end of the Civil War. A Radical Republican, he participated in the attempted impeachment

CHARLES SUMNER

BROWN BROTHERS

of President Andrew Johnson. In 1871, during Ulysses S. Grant's first presidential term, Sumner opposed the Administration's plan to annex Santo Domingo and opposed Grant in the presidential election of 1872. Summer died in Washington, D. C., Mar. 11, 1874. W. E. A.

**SUMTER,** a city in central South Carolina, the county seat of Sumter Co., situated in a rich agricultural area, 45 mi. east of Columbia. The region is heavily forested, furnishing the basis of much of the city's industry. Founded in 1799, Sumter was incorporated as a city in 1833. The city government is the council-manager type. Located in the city is the tomb of General Thomas Sumter, a hero of the Revolutionary War. In the vicinity is the Poinsett State Park. Sumter is the seat of Morris College for Negroes. Transportation is furnished by the Atlantic Coast Line and the Seaboard Airline railroads. In addition to furniture, the local factory output includes flooring, sash doors, lumber, cotton, cottonseed-oil products, machinery, veneer, garment hangers, caskets, trousers, and barrels. Pop. 1950, 20,185.

**SUMY** [su′mɪ], the name of a region and its administrative center in the northeastern Ukrainian S.S.R., in the western Soviet Union.

**The City.** Sumy is located approximately 90 mi. northwest of Kharkov. It is situated at the confluence of the Souma and Soumka rivers, on a bank of the Psel, in a dissected plain. Founded about 1652 by Ukrainian emigrants on the site of Lipensky, a village many centuries older, it suffered from Tatar invasions in 1658 and 1669. It became an important trading point for grain and held annual fairs which were widely popular. During World War II it was the scene of heavy fighting and was occupied by Nazi forces for several months. Sumy has good rail connections and trades in grain and sugar beets. Products include sugar, flour, agricultural machinery, textiles, leather, and lumber. Pop. (est. 1950), 70,000. C. C. H.

**The Region.** The Sumy Oblast (Region) is bounded by the oblasts of Bryansk on the northwest and north, Kursk on the east, Kharkov on the southeast, Poltava on the southwest, and Chernigov on the west. It covers an area of 14,818 sq. mi. The regional economy consists primarily of agriculture—cereals of all kinds, and industrial plants such as tobacco, flax, and hemp. The region produces large quantities of vegetables and a variety of livestock. Processing of tobacco, sugar, alcohol, flour, lumber, and food constitute the main industries. The industrial centers of the region are Sumy, Romny, and Konotop. Pop. (est. 1954), 1,800,000. W. S. V.

**SUN.** *See* SOLAR SYSTEM.

**SUNBIRD,** any one of a great number of species of small or very small (6 in. or less) songbirds united in the family Nectariniidae and allied to the flowerpeckers and honey eaters. It inhabits the tropical regions of Africa, Asia, and Australasia, and is characterized by a fairly long, curved bill and a tubular, protrusible tongue. The sexes are almost always differently colored, and the males have combinations of brilliant, often metallic, colors. As might be expected from its bill and tongue, it feeds wholly on the nectar of flowers and the small insects attracted thereto. Sunbirds have short, rather grating songs. Their nests are elaborate, hanging, purselike structures, often adorned with "tails" of cobweb and grass. In their food habits and iridescent plumage they closely resemble the hummingbirds of the New World, although the two families are in no way related to each other. H. G. De.

**SUN BITTERN,** a peculiar bird, *Eurypyga helias,* allied to the rails and cranes, found, in several varieties, from Guatemala to Brazil. It is about the size of a small heron, with a slender bill, a rather long, broad tail, and broad, rounded wings. It has a black head, with a white stripe above and below each eye, and a white throat. The rest of the plumage is an indescribable mothlike mixture of black, white, brown, gray, chestnut, and buff. It inhabits the wooded banks of streams, where it feeds on insects and small aquatic animals. During the season of courtship the wings and tail are expanded to display their curious markings. H. G. De.

**SUNBURY** [sʌ′nbəri], a city in east central Pennsylvania, the county seat of Northumberland Co., situated at the confluence of the north and west branches of the Susquehanna River, 42 mi. north of Harrisburg. The city is a shipping center for the coal and farm products of a wide territory. Founded in 1772 where Shamokin, an Indian village, once stood, Sunbury was incorporated as a borough in 1797 and as a city in 1922. The city government is the commission type. At Fort Augusta, built on the site of the city in 1756, the power of the French was broken during the French and Indian War. The fort became the refuge for survivors of the Wyoming Massacre. In Sunbury Thomas A. Edison in 1883 built and put into operation the first 3-wire, central station, electric-lighting plant in the world. Transportation is provided by the Delaware, Lackawanna and Western, the Pennsylvania, and the Reading railroads. Machine parts, silk, clothing, insecticides, and caskets are manufactured. Pop. 1950, 15,570.

**SUNDA ISLANDS** [sʌ′ndə], a chain of islands forming the Malay archipelago, which stretches eastward from the Malay peninsula to, but not including, the Molucca Islands, 7° N. - 11° S. lat., 95° - 128° E. long. The islands sepa-

rate the Pacific Ocean and its marginal seas from the Indian Ocean, and form the major part of the Republic of Indonesia. They are divided into the Greater Sunda Islands (Sumatra, Java, Borneo, Celebes, and adjacent small islands) and the Lesser Sunda Islands (Bali, Lombok, Soembawa, Soemba, Flores, Timor, and lesser islands in their vicinity). They are inhabited by nearly 70,000,000 people, over 49,000,000 of whom live on Java alone. R. G. B.

**SUNDAY, WILLIAM ASHLEY** (1862-1935), American evangelist, popularly known as Billy Sunday, was born in Ames, Iowa, on Nov. 18, 1862. He spent part of his boyhood in two orphan homes and worked his way through high school. His proficiency in baseball while playing on a local team in Marshalltown, Iowa, led him to a career in professional baseball, and from 1883 to 1891 he played successively on teams in Chicago, Pittsburgh, and Philadelphia. Sunday was converted in 1887 in a Chicago mission and after 1891 devoted himself to religious work, first in the Y.M.C.A. and after 1896 as a preacher. In 1903 he was ordained in the Presbyterian ministry and rapidly developed into the most widely known evangelist of his time. Utilizing a high-powered organization in carrying on his revivals, he attracted immense throngs and gained headlines in the newspapers. The number converted under his preaching is estimated at 300,000. Sunday's dramatic denunciation of the saloon and alcohol played a conspicuous part in his work and was a major influence in the adoption of the Eighteenth Amendment and of the "dry" experiment which followed. He died in Chicago on Nov. 6, 1935. W. W. S.

**SUNDAY.** To understand the meaning and significance of Sunday as the first day of the week it is necessary to consider the five contributions which have been made to its place in the calendar and to its manner of observance: (1) the worship of the sun among ancient peoples, (2) the popularity of Mithraism among the Romans, (3) the Roman observance of the day of the Sun, (4) the early Christian dedication of the first day of the week as a memorial of the resurrection of Christ, and (5) the Scottish Presbyterian conception of Sunday as a day of rest and the adoption of this conception by Puritan Massachusetts, with the resulting Sunday laws, usually known as Blue Laws.

From prehistoric times to the close of the fifth century of the Christian Era the worship of the sun was dominant. Deified in Egypt as Ra, the Sun-god, he is pictured in the oldest passages of the Pyramid texts. The sun-disk (Aten) with the outspread wings of the falcon became the most generally used symbol of Egyptian religion and has come to be widely known through such Biblical imagery as "the wings of the morning," and "the sun of righteousness . . . with healing in his wings." In Babylonia, cylinder seals picture the sun as a deity coming forth through open doors which attendants hold open for him, at the same time turning their faces away so as not to be blinded by his brightness. This idea of the sun having a habitation is reflected in the Biblical reference to his coming forth as a bridegroom from his chamber rejoicing as a strong man to run his course. When the Israelites entered Palestine they found the worship of the sun under the name of Baal-hammon, the latter part of this title meaning sun images. The sun was *baal,* or lord, just as the Babylonian sun-god Samas bore the title of *belu,* lord. It is of interest that in II Kings xxiii:11 there is a reference to the chariots of the sun. At the temple of the sun in Sippar in Babylonia there was also a chariot and horses dedicated to the god. Among the Hebrews were many idolatrous Jews who worshipped the sun, attracted to sun-worship under the influence of its frequency among the people of Canaan, and although laws were enacted against the practice (Deut. iv:19 and xvii:25), open idolatry continued long throughout Hebrew history.

At an early unknown date the mystery cult of Mithra or Mithras arose in Persia. In Zoroastrianism he is named Yazata, a power of light serving as aide to Ahura-Mazda. In the valley of the Euphrates he attained the eminence of an Assyrian god. Mithraism reached Rome in the second century B.C. It became popular in the Roman army, in the commercial class, and among the slaves and eventually was adopted by the Roman emperors because it supported the divine right of kings. Mithras, identified with Sol Invictus, gave authority and victory to the throne. From very ancient times, the Romans had marked each eighth day as a holiday. It is not surprising, since they were influenced not only by the favored cult of Mithras but also by the Egyptian cult in North Africa (a cult with which the Roman government was familiar), that they gradually came to observe a holiday dedicated to the sun. *Dies solis* was substituted for *dies saturni.* The earliest known Sunday law appeared in the edict of Constantine (A.D. 321) enacting that "magistrates, city people, and artisans" were to rest on the venerable day of the Sun. This law probably bore no relation to Christianity; the emperor as Pontifex Maximus merely added the day of the Sun to the Roman calendar and thus gave imperial recognition to the sun-worship which was already firmly established in Rome. Constantine's decree allowed agricultural labor on Sunday as work of necessity. The old market day was merged with Sunday. In this connection one may note that markets were held on Sunday in many parts of Europe until the late Middle Ages in spite of numerous papal edicts against them.

The early Christians had first adopted the Jewish seven-day week with its numbered weekdays, but by the close of the third century the planetary week and in the fourth and fifth centuries the pagan calendar names had become general in western Christendom. As noted above, during this same period the spread of Oriental solar religions had led in Rome to the designation of the day of the Sun as the first day of the planetary week. The Christians throughout the Roman world, therefore, had ready to hand a significant day on which to commemorate the resurrection of Christ, the "sun of righteousness." The New Testament contains clear evidence that from a very early period the first day of the week was observed by Christians as a day of assembly for "the breaking of bread" and perhaps for the collection of free-will offerings (Acts xx:7 and I Corinth. xvi:2). Justin Martyr in the middle of the second century describes how "on the day called Sunday" all town and country Christians assembled for instruction in holy writings, for prayer, distribution of bread and wine, and the collection of alms. Tertullian declared that the Christians "made Sunday a day of joy but for other reasons than to adore the sun which was no part of their religion." He was the first Church Father to declare that Christians ought to abstain on Sunday from secular duties and occupations. During the fourth, fifth, and sixth centuries there were numerous imperial decrees declaring with increasing stringency against labor on Sunday. Thus, from early times in its history the Church set aside Sunday as a holy day.

Beginning in the seventh century, strict observance of Sunday was demanded in England and such legislation continued to accumulate until the Act of 1871 which permitted certain kinds of work on the Lord's Day. All of the earlier

laws prohibited all kinds of labor and enforced attendance at church. Heavy penalties were ordered against violators. Particularly severe were the Sunday regulations in Scotland during the Reformation. The day was declared as a time for worship at church and in the home; no work of any kind (even agricultural) was permitted. Influenced by the Scotch standards the Separatists and later the Puritans inveighed against the laxity of Sunday observance countenanced by the Church of England at the time. In the American colonies, Sunday legislation began with an enactment of the Virginia colony in 1617 as an attempt to check the growing indifference toward religion in the spreading plantation. Until very recent times all of the states have passed laws prohibiting business on Sunday, and many states have legislated against sports, games, and the theatre on this day. Practically all of these Sunday or Blue Laws have ceased to be influential. Throughout the United States Sunday continues to be a day of worship. In many Christian communities it is referred to as the Sabbath, and the fourth commandment, "Remember the Sabbath day to keep it holy," is emphasized. Nevertheless, with the coming of the automobile, the moving-picture theatre, radio, and television and the interpretation of rest as relaxation and recreation, American Sunday observance has lost much of its historical austerity. "The Sabbath was made for man and not man for the Sabbath" has acquired broad social and hygienic significance. *See also* Blue Laws. A. L. H-Q.

**SUNDAY SCHOOL,** a type of school which had its historic beginnings in the work of Robert Raikes, a philanthropist of Gloucester, England. In 1780, Raikes established a school on Sunday for the instruction of under-privileged children who worked in factories all week and consequently had no time for school, either secular or religious. There were other contributors to the development of the Sunday school, but Raikes's idea spread more quickly. In the nineteenth century, Sunday-school development spread rapidly over the United States. In many places, then and later, the founding of a Sunday school preceded the establishment of a church. Also, as a result of the great shortage of ministers of the gospel existing at the end of the first half of the twentieth century, Sunday schools remained the only operative factor of some churches. Sunday schools, as the term is generally used, are purely a Protestant phenomena. The parochial schools of the Roman Catholics and of Judaism make provision for religious education, but most Protestant children attend schools where no religious instruction is given. The Sunday school accordingly fills a vital place in Protestantism. Of course, unlike the Sunday school established by Raikes, Sunday schools have become devoted exclusively to religious instruction, since secular instruction is obtained in the regular school curriculum. A. W. S.

**SUNDERLAND,** a seaport and county borough in Durham County, England, located about 10 mi. southeast of South Shields on the North Sea coast at the mouth of the Wear River. The most important commercial center of the county, its main industries are coal exporting and shipbuilding; of secondary commercial importance are breweries and manufactures of ship fittings and clothing. Shipbuilding has declined to some extent since World War II, although the arms of the river afford ideal conditions for shipyards and launchings. The adjacent coalfields of Durham have been extended under the sea near Sunderland, which is second among the Tyneside ports. Sunderland was an important glass-making town in the sixteenth century. The modern city has fine parks, an art gallery, libraries, an impressive Town Hall, and four miles of sandy beach for recreation. The Saxon monastery of Monkswearmouth, founded in 647, was the nucleus of the medieval settlement at Sunderland and the seat of St. Peter's, the famous school of the Venerable Bede, which remains the oldest building in the district. Sunderland returns two members to Parliament. Pop. 1952, 180,400. B. Su.

**SUNDEW,** a large genus, *Drosera,* of insectivorous plants of the sundew family, of which about 100 species are scattered over the world, chiefly in Australia. Seven are native to North America. These plants are perennial bog herbs, usually bearing leaves in a basal rosette and putting forth a slender, naked, flower stalk having a terminal, one-sided cluster of flowers opening only in the sunshine. The leaves, often rounded, are set with curious tentacles ending in reddish heads which secrete a glistening, honeylike fluid. Small insects, especially flies, mistaking the fluid for honey, become entangled in it. Thereupon the tentacles, by a downward movement, place the fly on the surface of the leaf, smother it, and secrete a digestive fluid which enables the leaf to assimilate the proteins of the insect's body and use them for plant food. J. C. Wis.

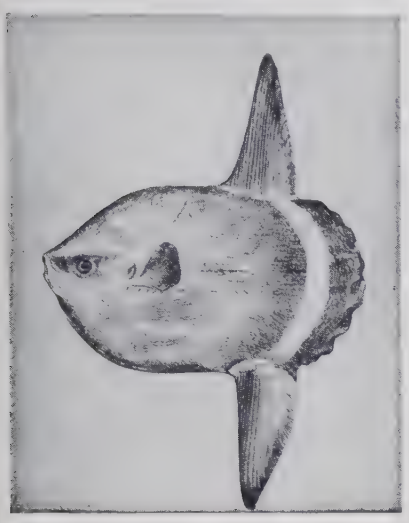
**SUNDOGS.** *See* Atmosphere (*Optical Phenomena*).

**SUNDROPS,** the common name of a genus, *Oenothera,* of the widely distributed evening primrose family. By some botanists, the genus is divided into numerous groups. The sundrops, chiefly native to the two Americas, usually have yellow flowers opening in the day. Various species are grown as ornamentals, especially the Ozark sundrops, *O. missouriensis,* and the common sundrops, *O. fruticosa,* which often have flowers 2 in. across. J. C. Wis.

**SUNFISH,** a small basslike fish of the family Centrarchidae with a deep, compressed body and spiny fin rays. The family is found only in fresh water in North America where there are many species. Some are very brightly colored with reds, oranges, and yellows, particularly during the breeding season in late spring and early summer. All are nest builders. The male clears and hollows out a saucer-shaped depression to a depth of approximately 4 in. He entices a female into the nest with a vigorous courtship. Later, he guards the nest and newly-hatched young. Most sunfish are small in size and seldom exceed 8 in., but are highly regarded as pan fish. All are carnivorous and eat insects, mollusks, crayfishes, and small fishes. Among the best known are the pumpkin seed, or common sunfish, *Eupomotis gibbosus,* and the bluegill, *Lepomis macrochirus.* Natural hybrids occur commonly among sunfishes. *See also* Bream; Crappie. E. C. R.

**SUNFISH, OCEAN,** *Mola mola,* a huge, grotesque fish of the family Molidae that lives in the open seas. It is often called a "headfish" because it gives the appearance of being one large oval head with the large dorsal and anal fins inserted far back on the body. These giant fish reach a length of 10 ft. and weigh more than 2,000 lb. Living near the surface, at times they may be seen lying on their sides basking in the sun. They feed on small fishes, crustaceans, and other small organisms which are picked up as they drift passively about. Often seen, they are easily captured since they permit a boat to come alongside and rarely try to escape by submerging. A thick layer of hard tissue under

the leathery skin helps protect them. The flesh is not generally eaten. A related species, the king of the mackerels, *Ranzania truncata,* a much smaller fish, only about 2 ft. long, has a proportionately longer body. E. C. R.



OCEAN SUNFISH, MOLA MOLA

COURTESY OF THE U. S. FISH AND WILDLIFE SOCIETY

**SUNFLOWER,** a genus, *Helianthus,* of the family Compositae having about 80 species of annual and perennial herbs, chiefly native to North America. The sunflower is a large, coarse plant having rough, triangular leaves which are usually opposite near the ground and alternate higher on the stems. The large flower heads, solitary or in clusters, terminate the stems and consist of a broad central disk of florets surrounded by conspicuous yellow rays. They bloom in autumn, turning each day to follow the sun from east to west.

The common sunflower, *H. annuus,* native from Minnesota to Texas, and state flower of Kansas, is sometimes used ornamentally and has great economic value. It is a rough, hairy annual growing wild, as high as 12 ft. It has toothed leaves 12 in. long, and large flowerheads. In the Soviet Union, its seeds are used for poultry feed. There is a small-seeded variety from which a valuable edible oil is produced, also oil cake for stock feeding, and oil for industrial uses. In the United States, the sunflower is grown sparingly for its seeds, but the plant is used for fodder and ensilage. Under cultivation, the sunflower may reach 17 ft. in height, and may have flower seeds 14 in. in diameter.

The Jerusalem artichoke, *H. tuberosus,* has fleshy roots often used as a vegetable. The willow-leaved sunflower, *H. salicifolius,* a perennial growing 10 ft. high, is native from Nebraska south, and has numerous flowers and attractive, refined leaves. Many hybrid sunflowers are grown for ornamental use. J. C. Wis.

**SUNGARI** [sʊ′ŋgɑ′rɪ′], the principal river of Manchuria. It rises in the mountains of Antung Province, near the northern boundary of Korea, and flows northward into the large Sungari Reservoir; from there it continues in a northwesterly direction to a point near Fuyu, where it is joined by the Nen River and turns sharply northeastward, finally emptying into the Amur River at Tungchiang. The total course of the Sungari is about 800 mi. For most of this distance, the river passes through one of the most fertile valleys of the world, where a large variety of crops, chiefly soybeans, are grown and where a temperate climate, resembling that of the central United States, prevails. Important cities along the river's course include Fuyu, Kirin, Harbin, Tungho, Ilan (Sanhsing) and Chiamussu. The Sungari is deep and usually is navigable by steamboat and junk as far as Kirin. It has numerous tributaries, chief of which is the southward-flowing Nen River. G. Q.

**SUNGKIANG** [sʊ′ŋjɪɑ′ŋ], one of the nine Chinese provinces in Manchuria created after World War II. It was formerly a part of the old Kirin Province. The new province of Sungkiang is situated at the southeastern corner of Manchuria, bordered by Korea on the south, Siberia on the south and east, Hokiang Province on the northeast, Nunkiang Province on the northwest, Kirin Province on the west, and Antung Province on the southwest. It has an area of 31,152 sq. mi. and had a 1947 population of 4,535,000. Mutankiang is the provincial capital.

**Topography and Climate.** The Changpai Mountains extend into this province from Kirin and branch off into three ranges, with Laoyehling in the center, Yingeling in the south, and Siaopaishan in the north. The largest river is the Sungari, which forms the northern boundary with Nunkiang Province. The Mutan Kiang (river), 342 mi. long, comes from Kirin and flows through the province in a northwesterly direction on its way to join the Sungari River in Hokiang Province. The city of Mutankiang is on the right bank of this river. In the south the Tumen Kiang, 286 mi. long and coming from Antung Province, forms a part of the boundary line between Sungkiang and Korea, and then flows through northern Korea to the Sea of Japan. The climate of Sungkiang is essentially continental, despite its proximity to the Sea of Japan. In summer the temperature sometimes reaches 95° F.; in winter it drops as low as —40°; the average winter temperature is —2°. Annual rainfall ranges from 18 in. in the north to 23 in. in the southeast.

**Economic Resources and Activities.** The soybean is the chief agricultural product, and is grown over almost the entire province. The Mutan Kiang Valley provides a fertile land for rice, corn, and tobacco. Ginseng is one of the medicinal herbs produced in Sungkiank. The Mutan Kiang Valley is rich in forests. Total timber reserves there are estimated at 117,250,000 cu. ft., with 40 per cent in Sungkiang Province and the rest equally divided between Kirin and Hokiang provinces. The trees are mostly birch, willow, and pine. Coal is mined in the southeastern part of the province. The largest mine is at Muling, with a reserve of 75,000,000 short tons and an annual output of 360,000 short tons. The Laotoukou mine has a deposit of 25,000,000 short tons and an annual output of 20,000 short tons. The reserves at Tungning and Holung combined are estimated at 190,000,000 short tons, but largely undeveloped. Gold is mined near Harbin, copper at Laotoukou, and silver at Tienpaoshan.

*Transportation.* There are three major railways, with a total of about 650 mi. within the province. The Chinese Changchun Railway, formerly the Chinese Eastern Railway, enters at Harbin and leaves Soviet territory at Suifenho. The Tumen Chiamussu Railway runs from Tumen, on the Korean border, to Chiamussu, on the Sungari River in Hokiang Province. The Kirin-Tumen Railway runs from Kirin, in Kirin Province, to the Korean border. The highways are inadequate. The three main roads are Chuho-Yenshou, Muling-Yenchi, and Mutankiang-Ningan. The Sungari River is navigable by steamboat along its entire length in this province during the summer, but becomes a thoroughfare for vehicles in the winter, when it is frozen. The Mutan Kiang (river) is navigable by wooden craft near the city of Mutankiang, while the Tumen Kiang

is navigable by small steamboat. Being an international river, the Tumen Kiang becomes a waterway of limited use because of official regulations.

**Cities.** Harbin, on the Chinese Changchun Railway and the southern bank of the Sungari River, is a leading metropolis in Manchuria. Since the puppet regime of Manchukuo, it has been made a special municipality, equivalent to a province in status. Situated about 500 mi. from Vladivostok and 600 mi. from Dairen, and linked with both ports by trunk lines of the Chinese Changchun Railway, Harbin became a communications and trade center between China and Russia about the year 1900. Its general appearance and atmosphere show a strong Russian influence. Its 1947 population was about 760,000. Mutankiang, the capital, on the right bank of the Mutan Kiang and at the junction of the Chinese Changchun and Tumen Chiamussu railways, had a 1947 population of 179,217. Many of its residents are Korean and Japanese immigrants. Yenchi, in the south, and Ningan, in the central west, are two other important cities, each with a population of about 27,000. *See also* KIRIN. A. C. T.

**SUNKEN BELL, THE.** *See* VERSUNKENE GLOCKE, DIE.

**SUNN HEMP,** the product of *Crotalaria juncea,* also called Madras and Bombay hemp. Widely used in India, where it is native, sunn hemp often takes the place of jute, and is also used for fish-nets, paper, and fabrics. It is one of the earliest fibers used by men. The plants, whose large, yellow, pealike flowers make them showy when in bloom, are also grown for hay and for green manure crops on many of the islands of the Pacific and in Florida. These shrubs reach a height of 8 ft. J. C. Wis.

**SUNNITE** [su'nait], the most numerous sect of the world-wide community of Islam. The Sunnites acknowledge the *sunnah* (custom, tradition, usage) of the Prophet and his companions. When Mohammed died on June 8, 632, he bequeathed to his followers a religio-political heritage, which gave them the ever-difficult task of finding an acceptable caliph (successor) to fill the highest office in Islam. The Sunnites believed that the theocratic state was an earthly dominion, headed by a caliph or Imam (leader), who was heir only to the secular, temporal office of Mohammed. Since the Prophet was called to his task by divine order, the Sunnites, unlike the Shiites, found it inconceivable that he could bequeath his charismatic mantle to anyone.

The complete silence of Mohammed on the subject of his successors sharpened in later Islamic history the cleavage between the Sunnites and their opponents. The Sunnites recognize the first four caliphs as rightful successors to Mohammed; they accept the six "authentic" books of Hadith (Tradition); and in jurisprudence they form their opinion in conformity with one or other of the four schools of law, which are discussed later in this article.

Constituting the majority of Moslems, the Sunnites have been the principal actors in the long history of the faith. Their first state, centered on Medina (A.D. 632-661), was presided over by valiant, patriarchal figures: abu-Bakr, Omar, Uthman, and Ali, and this initial period of Sunnite supremacy and expansion was encouraged in the establishment of the state of the Ommiads (A.D. 661-750), with Damascus as capital. The Sunnites carried the faith eastward to the frontiers of India, and westward into North Africa and Spain, where they sponsored powerful states. Under the Abbasside Caliphate (750-1258), the Mamelukes of Egypt (1250-1517), and other political regimes, the Sunnites played a most important part in the development of Islamic civilization. With the rise of the Ottoman Turks, who captured Constantinople in 1453 and overran Egypt in 1517, Sunnites continued for more than half a millennium as the stalwart champions of Islam. Since the two World Wars, the Sunnites, even without the caliphal symbol of imperial and spiritual authority, have asserted themselves in international affairs, particularly in relation to the creation of Pakistan.

The peculiarly Islamic science of Hadith (Tradition) owes its inception and growth to Sunnite piety, learning, and ingenuity. Hadith, the body of traditions carried back to Mohammed and his companions, is the basis of Sunnite Islam; Medina, capital city of Mohammed and his immediate successors, was the center of the new science of tradition.

Traditionalists assembled the sayings of Mohammed and his friends in accordance with a undeviating technique. Every tradition consisted of two parts: the *isnad,* a chain of narrators, concluding in the name of the highest authority who heard the saying from the lips of Mohammed or one of his associates, and the *matn,* the utterance as delivered. Bias and dishonesty reduced the value of narrators, but critical care was eventually taken to insure the relative genuineness of Tradition.

The canonization of six reliable books of Tradition crystallized Islamic religious thought. The first impressive compilation was that of al-Bukhari (died 870), a Persian Sunnite who traveled extensively in Arabia, Syria, Iraq, and Egypt, as well as Persia. His countryman, Muslim (died 874), was responsible for a similar collection under the same title. Four subsequent collections, which never acquired the dignity of the first two, were brought together by abu-Dawud of Basra (died 888), al-Tirmidhi (died c. 892), ibn-Majah of Qazwin (died 886), and al-Nasa'i (died 915).

The definitive text of the Koran was finally established in 933. Within the succeeding years, the exegetical works of al-Baydawi (died 1286), and others appeared. As an adjunct to these, the importance of Sunnite Tradition cannot be overrated. It shaped the Islamic heritage and set its religious tone for many centuries.

Equally significant was the formation within the framework of Sunnite Islam of four schools of jurisprudence. This took place during a time when orthodoxy was assailed by Mutazilite rationalism. Of the schools, the Hanafite is the oldest, the most liberal, powerful, and widespread, claiming the adherence of about one-half of the Sunnite population of the world, and prevailing numerically in the Near East, Central Asia, and India. Its founder, abu-Hanifah (700-767), advocated, in the adjudication of cases, the use of analogical deduction, but sanctioned at the same time recourse to "preference," in certain instances, in order to secure equity.

The extreme right wing of Sunnite jurisprudence was represented by the Hanbalites, a school committed to the defense of the fundamental faith against the inroads of freethought and heresy. Except for a few adherents in parts of Africa, this school nearly vanished long ago, but for the Wahhabi revival of the mid-eighteenth century in the heart of Arabia. The Malikite school of jurisprudence also owed its origin to a conservative revulsion against liberalism, though it never went to Hanbalite extremes. Today it prevails in eastern Arabia, North Africa, the Sudan, and Upper Egypt.

At Cairo is the tomb of al-Shafi'i (died 820), founder of a fourth school; and al-Azhar University is the repository of Shafi'ite teaching and its spearhead in the Moslem world. Born in Gaza, Palestine, al-Shafi'i was of Qurayshite origin; he spent his life in Iraq and Egypt. His rite is dominant in Lower Egypt, southern and northern Arabia, East Africa,

and Indonesia as well as the coastal regions of India and Palestine; and his is known as a tolerant, moderate school, cautiously accepting speculation.

The Sunnites—armed with their orthodox faith, exegesis, Koranic dogma, the canonical Tradition, and jurisprudence—fought medieval heresy and rationalism. Since the European Renaissance and the devastating attack upon religion by free inquiry and experimentation, they have sought to evolve a new theology affording the basis for a reasoned faith. Nationalism, secularization, and the impact of the new age, however, have scarcely allowed them the opportunity to refit their religious heritage for the modern world. E. J. J.

**SUNNYVALE,** a city in west central California, in Santa Clara Co., situated 32 mi. southeast of San Francisco. Fruit, poultry, and livestock farms and ranches are found in the surrounding area, for which Sunnyvale is a trade center. A feature of historic interest is the Martin Murphy, Jr., House, the frame of which was built in Boston and shipped around the Horn in 1849. Transportation is furnished by the Southern Pacific Railroad. Local industries include fruit and vegetable canning and the manufacture of road equipment and foundry products. Pop. 1950, 9,829.

**SUN ROSE,** a group, *Helianthemum,* of low woody or herbaceous perennial plants of the rockrose family having delicate roselike flowers whose petals open in the sun and often drop after a day of blooming. Of doubtful hardiness north of Philadelphia, though often grown in rock gardens and borders, the plants are generally evergreen farther south. The leaves are grayish, mostly opposite on the branches, the upper ones sometimes being alternate. The flowers, which have 5 petals, 3 or 5 sepals, and many stamens, are generally yellow, though there are also white, red, and pink forms. Late flowers often have very small petals, or none.

The species most frequently grown are *H. nummularium* and *H. grandiflorum.* The plants thrive in limestone soil, and are easily propagated by greenwood cuttings, by division of roots, or by seeds sown in spring. J. C. Wis.

**SUNSPOTS.** *See* Solar System (*Sun*).

**SUNSTROKE, TREATMENT OF.** *See* First Aid.

**SUN VALLEY,** a town and popular resort in central Idaho, beautifully situated in Blaine Co., 6,000 ft. above sea level, 98 mi. east of Boise, between Sawtooth National Forest and Challis National Forest, at the gateway to the forest and mountain areas of the state. It is internationally famous for its winter sports and is also renowned as a summer resort, with riding, hunting, and fishing that attract thousands. There is even a summer skating rink. The vicinity offers many interesting features, such as the Big Springs pictographs, the Map Rock, Thousand Springs, and Rock Cities. The town was built in 1936 by the Union Pacific Railroad, which serves the town of Ketchum, four miles southwest of Sun Valley. Pop. 1950, 428.

**SUN YAT-SEN** [sʊ′n yɑ′tsɛ′n] (1867-1925), Chinese statesman, first president of the Chinese Republic, was born of a peasant family at Choy Hung, near Macao. Some of his kinsmen had been involved in the Taiping Rebellion (1850-1864), and he himself, while living during boyhood with one of his brothers in Honolulu, Hawaii, became converted to Christianity as a Protestant; from his earliest years, his personality was marked by the double traditions of Chinese revolutionism and Western spirituality. Sun prepared for a medical career, studying in Hong Kong under Sir James Cantlie, a pioneer researcher into the bubonic plague. He was probably the first Chinese ever to qualify for the degree of M.D., but throughout life his practice of medicine was merely incidental to his career as revolutionist.

From his earliest years, Sun Yat-sen had a sense of mission. He felt that he was the man of destiny who would awaken China, restoring its ancient civil virtues and teaching it how to become modern, efficient, productive, and powerful in a world of armed, sovereign nations. His revolutionary technique consisted, first, of the consolidation of the pre-existing anti-Manchu secret societies; second, of their linkage with the modernized Chinese overseas (especially in the United States, the Philippines, Malaya, Japan, and France); third, of the instigation of revolutionary "incidents" which might sweep the torpid masses of China to the revolutionary banner; and fourth, to the planning of a revolutionary administration. In 1894 he called his newly-founded revolutionary confederation the Save China League (Hsing Chung Hui); in 1905 he proclaimed the San Min Chu I and reorganized the party as the League of Common Alliance (Tung Mêng Hui). Sun himself wandered all over the world, studying politics, socialism, land reform, and revolutionary techniques. He gained millions of Chinese followers and became the acknowledged leader of the republicans.

*SUN YAT-SEN*

BROWN BROTHERS

In 1911 an incident at Wuchang precipitated the revolutionary landslide. Sun Yat-sen, then in Denver, Colo., was notified by telegram in code that the revolution had begun and would probably succeed. He returned to China by way of London, seeking British financial support for the emergent republic, and arrived in China in time to take the oath of office as first president of the Republic of China on Jan. 1, 1912. By taking the oath, he lost the American citizenship he had previously gained as an ex-subject of the Hawaiian king.

Following this apparent success, Sun went through years of disappointment. His revolutionary organization, renamed Kuomintang, failed to win control of the new republic. Sun himself relinquished the presidency to the imperial general, Yüan Shih-k'ai, as a means of winning imperial assent to the revolution. Yüan promptly established a pyramid of military dictatorships and began to plot his own enthronement. Sun went into opposition in 1913 and began a succession of revolts, intermittently holding the presidency of unstable revolutionary governments at Canton. He failed to get British or American help in restoration of the republic, and in 1922 accepted the proffered aid of the Third Interna-

tional. With Russian funds, arms, and personnel, the Kuomintang and the Canton government were reorganized. Sun tried to use the Communists while opposing Marxism. In 1924 he gave the lectures which provided the definitive form of the San Min Chu I.

San Min Chu I, the official ideology of both Nationalist and Communist China, is based on the principles of race-nationalism, democracy, and Min Shêng. Race-nationalism, on a basis of Confucian morality joined to Western technical skills and science, was to unite all Chinese throughout the world under the Kuomintang, which was to seek help abroad through alliance with subjugated colonial peoples against the white race (pan-Asianism) and with Communists against capitalism (class war of nations). Sun held that democracy could not be achieved in China simply by giving the vote to the masses, but that its realization must go through three stages: unification by Kuomintang armies, temporary one-party dictatorship by Kuomintang officials, and finally self-government by the free action of the electorate. Min Shêng (or "people living on") was a sort of economic experimentalism, rejecting both unrestrained capitalism and class-war communism. However, Sun's vagueness as to practical measures has allowed a great variety of interpretation of these principles among his followers.

Sun's first wife bore him two daughters and one son, Sun Fo (Sun K'ê). His second, the former Ching-ling Soong, was the sister of T. V. Soong and sister-in-law of H. H. Kung; her youngest sister later married Chiang Kai-shek, who is thus Sun's second wife's brother-in-law. On Mar. 12, 1925, while seeking a negotiated peace with the modern war lords, Sun died in Peiping. Under the honorary name of Chung Shan ("Middle Mountain"), taken from a revolutionary alias, and with the perpetual post, even in death, of Tsung-li ("Party Leader") of the Kuomintang, Sun is recognized by all factions as the greatest Chinese of modern times. His tomb at Nanking, the most spectacular modern building in China, has become a national shrine.

**SUOMI.** *See* FINLAND.

**SUPERIOR,** a port of entry in the northwestern corner of Wisconsin, the county seat of Douglas Co., at the head of Lake Superior, and bounded by the St. Louis and Allouez bays and St. Louis and Nemadji rivers. It is just south of Duluth, Minn., and 125 mi. northwest of Eau Claire. Superior, located in the richest iron-ore district in the nation, is an important shipping center for iron, grain, and coal. The French visited the city's site as early as 1661, and trading posts were established on the point by the Hudson's Bay Company, the Northwestern Fur Company, and John Jacob Astor's American Fur Company, but the permanent settlement of the community did not begin until 1853 when the first log house was constructed. The small settlement became a lumbering and shipping community, which was incorporated as a village in 1887, six years after the first railroad reached the site. Superior was incorporated as a city in 1899; it has the city-manager form of government. The city has a state teachers' college. Superior is not only a leading shipping and industrial city, but it is also a popular resort community because of its location on the lake and its proximity to numerous small lakes and streams with excellent fishing and other recreational facilities. It is in the renowned Northern Woods vacation area of Wisconsin. In the vicinity are the 140-acre Pattison State Park, containing the noted Big Manitou Falls and the Douglas County Upland Bird Sanctuary.

In addition to the lake steamers, the Wisconsin Central, the Northwest, and the Trans-Canada air lines and the Chicago, Milwaukee, St. Paul and Pacific, the Chicago and North Western, the Great Northern, the Duluth, South Shore & Atlantic, the Northern Pacific, and the Minneapolis, St. Paul & Sault Ste. Marie railroads supply transportation. Superior contains three connecting harbors with numerous iron-ore docks, ten coal docks, and eight grain elevators with a capacity of 30,235,000 bu. Shipyards, flour mills, lumber yards, railroad shops, and briquet plants are among the city's chief industrial establishments. Other industrial plants include in their varied output steel products, machinery, furniture and other lumber products, cement, and canvas. Pop. 1950, 35,325.

S. D. M.

**SUPERIOR, LAKE,** the largest body of fresh water in the world, and the northernmost and westernmost of the five Great Lakes of east central North America. Lake Superior is on the Canadian-United States border, and is bounded on the north and east by Ontario, Canada. The Michigan Upper Peninsula and Wisconsin form its southern, and Minnesota its western, boundary. It extends from 46° 25′ to 48° 57′ N. lat. and from 84° 22′ to 92° 06′ W. long. and is 383 mi. long and 160 mi. wide, with an area of 31,820 sq. mi., of which 20,620 are in the United States. The lake surface is 602 ft. above sea level, the maximum depth 1,302 ft., and the average depth about 475 ft. Lake Superior has a fairly regular coastline of 1,500 mi., but has some bays, peninsulas, and islands. The larger bays are Thunder, Black, Nipigon, and Heron on the north coast, and Chequamegon, Whitefish, and Keweenaw on the south. The Keweenaw Peninsula of upper Michigan is the largest in the lake. Sizable islands are Isle Royale, St. Ignace, Simpson, Michipicoten, Cooper, Grand, Manitou, and Slate and the group of Apostle Islands. The drainage basin covers 80,900 sq. mi., of which 37,570 are in the United States.

Lake Superior drains southeastward through the 63-mi. length of the St. Marys River into Lake Huron. The famous Sault Ste. Marie canals built around the mile-long rapids in the St. Mary's River accommodate more commercial freight tonnage than any other canal-system in the world. Cold weather, ice, and storms close Lake Superior from about mid-December until the last of April. The most important cities on Lake Superior are Fort Williams, Port Arthur, Nipigon, Michipicoten, and Sault Ste. Marie, Ontario; Sault Ste. Marie and Marquette, Mich.; Superior and Ashland, Wis.; and Duluth and Two Harbors, Minn. Duluth alone clears more than 38,000,000 tons of freight annually, mainly iron ore and wheat. Superior, like the other Great Lakes, was formed by the action of continental glaciation; it was explored in 1616 by Étienne Brulé.

**SUPPÉ, FRANZ VON** [zu'pe] (1820-1895), Austrian composer, was born in Spalato (Split), in Dalmatia on April 18, 1820. After serving as conductor in various theatres in Austria, he settled in Vienna in 1861 and remained there until his death. His output as a composer was large, including two grand operas, forty-six operatic pieces, and numerous farces and vaudevilles, as well as a mass and a requiem. He is best known outside his native country for the overtures *Poet and Peasant,* and *Light Cavalry* (1866). Von Suppé died in Vienna, May 21, 1895.

D. L. E.

**SUPPLY AND DEMAND, LAW OF,** a basic part of the economic theory of value and price. It may be stated as follows: if other things remain unchanged, the price of economic goods in a free market will change directly with demand and inversely with supply. It should be emphasized that, according to the law, price is determined by supply and demand. It is improper, therefore, to say that in a given market, at a given time, the demand dropped because the price rose. What is meant is that the quantity taken was less than it would have been if the price had been lower. This fact is shown in the schedule of quantities that could be taken at different prices. Supply and demand change only when there is a change in the quantities that could be purchased or offered at specific prices. Such factors as the time covered, the process of production, and the character of the goods priced, affect the relative importance of demand and supply in determining price. Economists who urge that free operation of the law ensures the best use of resources hold that if sufficient time is allowed, adjustments in the supply and demand for given goods will occur automatically until a price is reached at which the supply brought into the market will exactly equal the quantity that buyers can and will take. **SURAT** [sʊræ′t; su′rət], the chief city of Surat District in Bombay State, India, near the mouth of the Tapti River, about 170 mi. north of the city of Bombay, at 21° 10′ N. lat. and 72° 50′ E. long. Surat was once one of the most important cities in India and by 1500 was a prize sought by European countries. The first Europeans to reach Surat were the Portuguese, who destroyed the city three times in the early sixteenth century and controlled both the port and the coast for nearly 100 years. In 1612 the English routed the Portuguese and captured Surat. They built a factory, established the first trading post of the British East India Company, and made the city the seat of British government in India. Surat prospered and its population is said to have exceeded 800,000. The British, however, obtained the port of Bombay and made it the chief port of the East India Company in 1668, possibly because the harbor at Surat was small, shallow, and heavily silted. Thereafter Surat declined; its population shrank to 80,000 by the middle of the nineteenth century. Industrial development since that time has helped Surat to regain some of its former commercial importance. Manufactures include cotton cloth, striped silk, silk and gold brocades, jari work, sandalwood inlay work, silver objects, and gilt wire. Surat lies on a low, flat plain in a belt of fertile black soil. Cotton, rice, castor beans, and sugar cane are grown. To the west, along the coast, there are salt marshes and mangrove forests; to the east and south is an area of orchards. The annual rainfall is 30 to 50 in., mostly in summer. The railroad from Bombay to Baroda passes through Surat. It is an educational center. Almost a quarter of the Parsees of India live in the city. Pop. 1951, 223,182. R. W. Cr.

**SURESNES** [süre′n], a river port on the Seine, 3 mi. west of Paris at the foot of Mont Valerien. In 1593 Suresnes was the scene of a convention of French deputies, one of the results of which was the conversion of Henry IV to Catholicism, the state religion. Located in the city is an American cemetery for Americans who died in Paris hospitals during World War I. The city's industrial plants include machine shops, printing establishments, and automobile, bicycle, aircraft, textile, chemical, and perfume factories. Pop. 1954, 37,149. W. McE.

**SURETY BONDS.** *See* Insurance (*Fidelity and Surety Bonds*).

**SURFACE,** the surname of three characters in *The School for Scandal* by Richard Brinsley Sheridan: Joseph, Charles, and their uncle, Sir Oliver, who returns from abroad and tests his nephews by observing their behavior before identifying himself. A. H. N.

**SURFACE PHENOMENA,** those physical and chemical phenomena which occur at the areas separating matter of different properties in any two of its three states—solid, liquid, and gaseous. These areas of separation, known as interfaces or boundaries, may be subdivided into mobile or immobile interfaces. Liquid states of matter are involved in the mobile interfaces. Thus, in mobile interfaces, there may be a liquid-gas interface or an interface between two liquids. Correspondingly, there are immobile interfaces between a solid and a gas, a liquid, or another solid.

Surface phenomena become progressively more important as the area of interface between the two states is enlarged. Thus, the more finely divided the liquid or solid that yields the mobile or immobile interface, the more important will the surface phenomena become.

**Brownian Movement of Motion.** In 1827 an English botanist, Dr. Robert Brown, observed a continuous, haphazard, vibratory motion shown by pollen grains suspended in a liquid when viewed under a moderately high-powered microscope. He satisfied himself that the motion was peculiar to finely-divided solid particles in suspension and was not due to such forces as convection or to evaporation, attraction, or repulsion of the particles. It is now known that the motion is due to the impacts of the liquid molecules on the finely-divided particles. These impacts do not cancel each other at every instant and so produce the irregular motion observed. The individual motions cannot be observed, since it has been computed that these occur as often as 100 million million million times a second. Gross displacements of individual particles can be observed, however. The theory of such motion has been worked out by Einstein, Smoluchowski, and others, while the practical experimental observation of such motions and their consequences has been made by J. B. Perrin in France and by T. Svedberg in Uppsala, Sweden. It is now known that the average of the squares of the displacement, $d^2$, is proportional to the time, $t$, and to the absolute temperature, $T$, and is inversely proportional to the radius of the particle $r$, and to the viscosity, $\eta$, of the liquid in which the particles are moving. Included in the equation are the gas constant, $R$, and the so-called Avogadro constant, $N = 6.02 \times 10^{23}$, the number of gas molecules in 22.4 liters of any gas. The equation becomes:

$$d^2 = \frac{RTt}{N 3 \pi r \eta}.$$

The gas constant, $R$, and the Avogadro number, $N$, enter the calculation because the theory of Brownian motion is parallel to that which describes the theory of motion in the particles, or molecules, of any gas, the so-called kinetic theory

of gases. A similar equation describes the time which a gas molecule will take to go from a given distance inside a gas volume to the wall of the containing vessel.

**Diffusion.** The same type of reasoning leads to conclusions as to the rate at which finely divided particles will migrate through a suspension. The rate of this diffusion is proportional to $RT$ and inversely proportional to the Avogadro number $N$ and to the frictional coefficient, $f$, which in the case of a spherical particle is equal to $6\pi r\eta$, where the symbols are the same as in the preceding equation:

$$D = \frac{RT}{Nf} = \frac{RT}{6\pi r\eta} \qquad \text{(for a sphere)}.$$

**Sedimentation.** The more finely divided the particle, the greater the interfacial surface, and the longer will the particle take to settle in any medium. The phenomenon of dust storms in the Dust Bowl is due to slow sedimentation of finely-divided particles of dust in the air. Quicksands and sludges are due to the slow rate of settling of finely-divided solid particles in a liquid medium. Here, the rate of fall, $V$, through the medium is determined by the force of gravity, $g$, acting on a particle the volume of which is $\frac{4}{3}\pi r^3$ and whose density is $d$. It is inversely proportional to the viscosity of the medium in which the particle falls. That is,

$$V = \frac{\frac{4}{3}\pi r^3 dg}{6\pi r\eta} = \frac{2r^2 dg}{9\eta}.$$

The smaller the radius, the slower the velocity of fall. Many milky liquids consist of extremely finely-divided, white particles in suspension in the liquid medium. Although these particles are intrinsically denser than the medium, the velocity of their fall is so slow, because of the smallness of their radius, that years may elapse before sedimentation is achieved. It is known that the stability of these suspensions is due in part to the electrical charges that the individual particles acquire and retain in the solution. Frequently, the suspension may be discharged and sedimentation achieved by changing the electrical charge which the particles carry.

**Surface Tension.** The approximately spherical shape of a small drop of water or quicksilver is due to a surface force or tension present at all liquid surfaces, which acts to

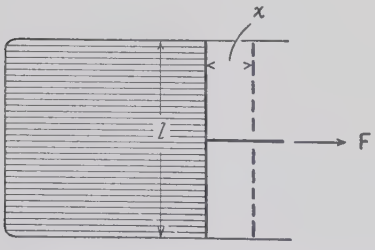

*Fig. 1—LIQUID FILM ENCLOSED IN A WIRE "CYLINDER AND PISTON"*

make the total surface area or interface as small as possible and hence to approach the sphere in shape. The operation of these surface forces can be shown in a variety of ways. If a small film of water is enclosed in a U-shaped wire and closed with another wire acting as a piston, as in Fig. 1, the film can be expanded or contracted by forces exerted on the piston. These changes increase or decrease the area of surface exposed by the water film. If a force $F$ is applied to the piston wire of length $l$, the force $F$ exerted is related to the surface tension by the expression $F = 2l\gamma$ (surface tension). The number 2 comes into the expression because the film has two surfaces. The surface tension is usually represented by the Greek letter $\gamma$, so that $F = 2l\gamma$. If the piston moves a distance $x$, the increase in film area is $2lx$, and so $Fx = 2lx\gamma$. Surface tension therefore may be defined as the force in units (dynes) per unit length of surface of a liquid parallel to the surface. The connection with the contractile force in a liquid arises because the molecules within the body of a liquid are acted upon equally in all directions by forces exerted by other molecules. The molecules at the surface of the liquid, however, are acted upon more strongly on the liquid side than on the vapor side. The work that must therefore be done in pulling new molecules to the surface by increasing the surface area is measured by the work done in creating the increased surface, $2lx\gamma$.

Surface tension can be measured indirectly by measuring the mass of a drop of liquid which falls from an orifice.

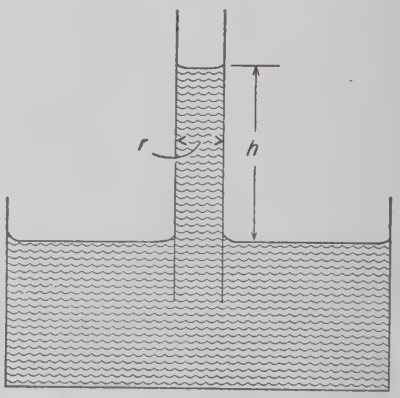

*Fig. 2—RISE OF LIQUID IN A CAPILLARY TUBE*

It may also be measured by the rise of liquid, $h$, in a narrow or capillary tube. In Fig. 2, the surface tension, $\gamma$, operates at the circumference, $2\pi r$, of the tube of radius $r$. The force of surface tension is balanced by the pressure due to the column of water, of volume $\pi r^2 h$, of density $d$, acted on by gravity, $g$. Hence:

$$2\pi r\gamma = \pi r^2\, hdg, \text{ and}$$
$$\gamma = \tfrac{1}{2}\, rhdg$$

In a tube of known radius $r$, the surface tension is therefore measured by the height of rise and the density of the liquid.

Surface tension or, more precisely, interfacial tension, is also manifested between two liquids. Thus, drops of oil form in water; whether they rise or fall depends on the relative densities of the two liquids. The surface tension is measurable by the same methods used with liquids in air, for example, by measuring the mass of drops formed by one liquid at an orifice in another liquid.

**Surface Films.** Surface forces, or interfacial forces, are responsible for the spreading of oil films on water, as in the case of castor oil. They also are responsible for the behavior of certain oils, principally pure mineral oils, which do not spread on water but form lenses on it. Chemical interactions are responsible for the different behavior: oils that spread cause a lowering of surface tension, whereas nonspreading oils prefer close association with themselves rather than with water molecules. The researches of Lord Rayleigh, Miss Pockels, Irving Langmuir, W. D. Harkins, N. K. Adam, and others led to the conclusion that oils which spread on water form a single layer (a monolayer) of oil molecules on the surface. The molecules are arranged in a definite pattern on the surface. The water-soluble or polar portion of each molecule is held down at the water surface. The water-insoluble portion of each molecule tries to get away from the surface. Nonspreading oils have no polar or water-soluble portion. They therefore lie as a lens on the water surface.

An oil film on water may be "gaseous" or "condensed."

Gaseous films occur when each oil molecule is separate from its neighbors on the surface. In condensed films, the oil molecules are crowded compactly together. These two possibilities are shown in Fig. 3.

The gaseous film acts like a two-dimensional gas with a definite surface pressure $F$. The product of the force $F$ and the area $A$ occupied by the film is constant at constant temperature, $FA = kT$. If the film is compressed sufficiently, the individual oil molecules become more and more crowded on the surface until finally they become close-packed. At this

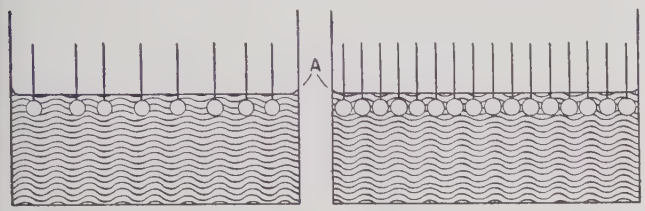

*Fig. 3—PHENOMENA OF AN OIL FILM ON WATER*
*(a) "Gaseous" film; (b) "Condensed" film*
*O = polar end of each oil molecule;*
*— = nonpolar end of each oil molecule; (A) Surface of water*

point, the force $F$ rises steeply. The area at the point of steep rise is then the cross-sectional area of the molecule in its position of orientation on the surface. Langmuir was thus able to measure the cross section of a variety of molecules and, hence, to calculate from the volume what the length of each molecule must be. His results were verified later by X-ray measurements.

Condensed films may be "liquid" or "solid." Such films can be studied when spread as monolayers on water, with cylinder oil as a multilayer boundary showing interference colors and thus indicating the area of spread. Solid films so formed show a serrated edge and can be torn apart by a drop of cylinder oil placed in the center of the film. Liquid films have a circular outline, and the cylinder oil added to the film center will spread circularly (*see* Fig. 4).

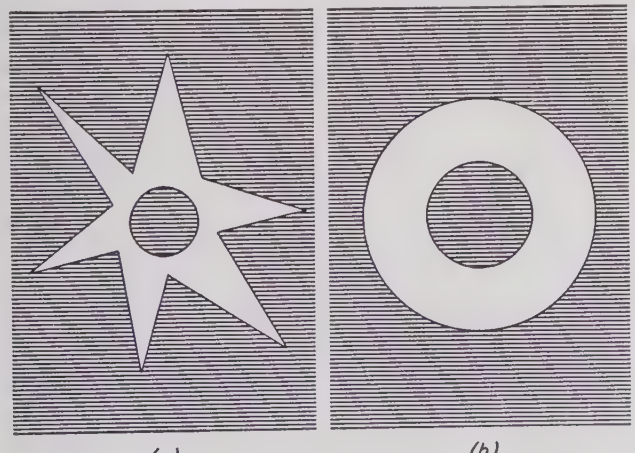

*Fig. 4—PHENOMENA OF A CONDENSED FILM*
*(a) "Solid" condensed film; (b) "Liquid" condensed film*
*(Shaded areas are cylinder oil.)*

**Multilayer or Built-up Films; Lubricants.** In 1935, Katharine Blodgett developed a method of building up successive monolayers on a surface by dipping polished metal sheets into, and withdrawing them from, a monolayer of the material spread on water. The pattern of build-up is shown in Fig. 5. The properties of lubricating oils are, in part, dependent on the capacity of bearing surfaces to abstract from the lubricant materials which build up on the surfaces of the moving parts, and so decrease the friction that would otherwise obtain if such films were not present.

Antireflecting coatings on glass are produced by the formation of built-up films on the glass surface. These films may consist of barium stearate (Blodgett) or of fluorides of magnesium or calcium (C. H. Cartwright). Etching off the oxide surface of glass is an alternative method of producing the nonreflecting surfaces. The individual lens elements of lenses for cameras, motion-picture cameras, and projection apparatus are thus covered with built-up

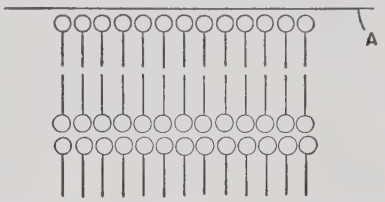

*Fig. 5—REPEATING PATTERN OF ORIENTED OIL FILM ON METAL SURFACE*
*(A) Edge of metal surface*

films to increase the light transmission. An increase in illumination as high as 30 to 40 per cent can be secured by this method.

**Adsorption; Chemisorption.** Solid surfaces have also the capacity to condense or adsorb gases and vapors on the surfaces (that is, to make them adhere in a thin layer) by reason of the residual forces in such surfaces; moreover, they have the capacity to adsorb the constituents of a solution from such solutions. These surface forces have important practical applications. Substances with extended surfaces, such as charcoal and silica gel, can be used for clarifying solutions by adsorbing the coloring matter in the solutions; for dehumidifying or drying air or vapors by adsorbing water vapor; in solvent recovery by adsorbing vapors from low concentrations of these in gases; and in gas masks to adsorb toxic gases, and so to remove them from contaminated air. A wide variety of chemical substances, notably nickel, platinum, iron, cobalt, silver, copper, zinc oxide, chromium oxide, and other oxide mixtures, can be used as catalysts to promote the speed of chemical reactions. Such substances can be brought into a condition of extended surface and can then bind gases and vapors to their surfaces in chemically active form by processes which are known by the term chemisorption.

Adsorption at surfaces can be caused by physical or by chemical forces. Physical adsorption is analogous to liquefaction and involves similar forces. Heat is generated by the adsorption process. In physical adsorption, the heat is comparable to the heat of liquefaction. At low concentrations of vapor, the layer of adsorbed material does not normally exceed a monolayer. Close to the condensation point, multilayers will form; and if there are pores, these will fill with liquid. In chemisorption, the binding to the surface is much closer, and involves much stronger and quite specific chemical forces: the heats developed may be one or two orders of magnitude greater than those involved in physical adsorption; the adsorbed layer is never more than one layer thick; and, in the process, the substance adsorbed may undergo a considerable structural change. Thus, hydrogen, the molecules of which contain two atoms, $H_2$, is completely dissociated at many metal surfaces and each hydrogen atom is separately bound to a surface metal atom, Me-H. Such hydrogen atoms, so bound, are in general more reactive than hydrogen molecules and so may join with other molecules more readily.

The adsorbent surface thus behaves as a catalyst or accelerator of chemical reaction.

Because adsorption is always accompanied by liberation of heat, the extent of adsorption at a given concentration of gas or vapor decreases with increasing temperature. Contrariwise, it increases with decreasing temperature. Charcoal, at liquid-air temperatures, has an enormous capacity to bind gases to its surface by adsorption. Thus, it may be used to remove practically all the gas molecules from a given container, so producing high vacuums in filament lamps, vacuum tubes, or thermos vessels. Chemisorption may be highly dependent on temperature, not occurring at all at low temperatures, at which only physical adsorption then occurs. Chemisorption sets in as the temperature is raised. At sufficiently high temperatures, the capacity of the surface to hold the gas, even by chemical forces, decreases; and, so, in such temperature ranges, the surface becomes progressively barer with increase of temperature.

Adsorption varies directly with the pressure. At low pressures of gas and vapor it is proportional to the gas or vapor pressure. At high pressures, the adsorption becomes independent of the pressure because the surface is saturated. In solutions, the concentration of the substance adsorbed plays the same role as pressure in gaseous systems. At low concentrations, adsorption is proportional to the concentration. At high concentrations, the surface becomes saturated, and adsorption is constant and independent of concentration.

In the case of most adsorbents, the surface is not uniform. For these, it is found that the adsorption, $x$, is proportional to a fractional power of the pressure, $p$, or the concentration, $c$. Thus:

$$x = kp^{1/n} \quad , \quad \text{or} \quad x = k^1 c^{1/n} \quad .$$

The concentration in the surface layer of a solution can also be related to the interfacial tension of the solution by a mathematical deduction due to Willard Gibbs. There is an excess of solute in the surface of any solution when that solute decreases the surface tension. When the solute increases the surface tension of a solvent, there will be less solute in the surface than in the body of the solution.

**Surface Energy of Small Particles.** As particles are subdivided, the area increases, as does the free energy of the surface. As a consequence, finely-divided particles have a larger solubility and a higher vapor pressure than larger particles, accounting for the change in particle size of precipitated powders on standing in solutions. The coarser particles grow at the expense of the finer particles, which tend to disappear.

The same phenomenon occurs in fogs and clouds. The finer particles evaporate and condense on the coarser particles. In this way, clouds change into raindrops. A similar process is responsible for the conversion of clouds to snowflakes. These factors are basic to the methods proposed for producing rain or snowfall by "seeding" clouds with dry ice, silver chloride, or even fine water sprays.

**Smokes and Fogs.** The rapid combustion of a wide variety of materials in a large excess of air produces smokes that consist of finely-divided particles in the gas. The rapid expansion of high-boiling liquids into large volumes of air will produce stable fogs of great screening power. Thus, Langmuir and Schaefer produced efficient wartime fog screens by evaporating high-boiling oils through nozzles at supersonic velocities into air. The procedure produced fog particles of extremely small dimensions and of corresponding stability with which wide areas could be screened much more effectively than with the most efficient smoke screens. Fogs and smokes of this maximum stability have also the capacity to pass through filters with minimum retention. It is possible, therefore, to produce toxic smokes of such a small particle size that they will pass through the ordinary type of gas-mask canister without being removed, necessitating the development of special filters.

**Electrical Effects on Fine Particles.** The effect of charged particles in promoting the agglomeration of fine particles is well known to physicists who use the Wilson cloud chamber. In this chamber, supersaturated water vapor is condensed to fog tracks along the path of electrons, or electrically-charged particles of matter or ions are introduced into the cloud chamber by the ionizing influence of alpha particles, protons, cosmic rays, and the like. Sir Oliver Lodge made early experiments to precipitate fog and to dissipate smoke by charging the air over cities electrically at high voltages. About 1911, F. G. Cottrell developed the principle of electrical precipitation of suspended particles to such a point that commercial application became feasible, and it was applied to industrial smokes. Precipitation occurs readily on flat surfaces if placed opposite points charged to a high potential of 20,000 to 30,000 volts. The air space between surface and points becomes charged and the charge is communicated to particles passing through the air space. So charged, the dust particles travel to the flat surface, and there they adhere.

In liquid systems, small suspended particles can acquire electrical charges by adsorbing on their surfaces ions present in the system from dissolved salts. These charged particles will move under the influence of an electric field, in a fashion dependent on the charge they carry. This migration under an applied field is known as cataphoresis. This principle has been used to build up structures from fine liquid or solid particles. Thus, finely-divided rubber latex can be made to migrate to a surface and thus build up rubber articles in the form of thin rubber coats on a prepared mold. Rubber gloves can be made thus. Conversely, when a liquid is streamed through a porous diaphragm composed of such fine particles, an electrical current can result from the streaming process. This is known as electrical endosmose.

The charge carried by a finely-divided particle in a solution containing ions is dependent on whether an excess of positive or negative ions is adsorbed under the given conditions. As a simple illustration, a particle of silver chloride is composed of silver ions and chloride ions, and these are found in approximately equal numbers on the crystal faces. If the particle is placed in a solution of a silver salt, an excess of silver ions will be adsorbed on top of the chloride ions in the surface; the particle will show a net positive charge. If the particle is placed in a solution of a soluble chloride, say sodium chloride, the chloride ions will be adsorbed in excess on the silver ions of the particle surface; the net charge on the particle will now be negative. As long as the particles are all charged positively or all charged negatively, they tend to repel each other; coalescence does not occur. When, however, there are both positively and negatively charged units present, these will neutralize each other and cause coagulation or precipitation. Thus, if silver nitrate solution is added to a solution of a chloride, drop by drop, or if the addition is reversed, chloride being added to nitrate, in each case, a milky-white liquid of finely-divided silver chloride, carrying one or the other charge, is formed. However, when a certain quantity of either reagent has been added to the solution, in each case the charge will become balanced, positive and negative; coagulation will occur as a stringy precipitate, with the supernatant liquid no longer milky but clear.

**Gels and Jellies.** Many substances precipitate from solutions as fibrous structures that form clusters or networks. Many of these structures adsorb water strongly. A small amount of precipitate is thus able to immobilize a large amount of water. The solids so constructed are known as gels or jellies. Other liquids than water can be so immobilized by adsorption on suitable network precipitates. In "canned heat" for example, alcohol is available in a solidified network or "brush-heap" structure.

**Emulsions and Foams.** Two immiscible liquids can be caused to form a quasi-hemogeneous liquid system of good stability, known as an emulsion. In reality, one liquid is finely dispersed in the other, which forms the continuous phase. Emulsions may be of the oil-in-water type or the water-in-oil type, depending on the conditions. The stability of such emulsions is in large measure dependent on stabilizers which concentrate at the interface between the oil and water. These stabilizers will normally be molecules, part of the structure of which is soluble in the oil, and the other part soluble in water; thus, they act as links between the two liquids at the interfaces.

Foams form on all solutions that show an appreciable lowering of the surface tension of the solution. They are produced by shaking the solution. The stability of such foams will vary considerably. To get a stable foam, the surface film must be of itself viscous or be made so by adding suitable agents to the interface, for example, fine powders. This surface phenomenon is of importance in cleansing and detergence. The solid particles constituting the dirt are so abstracted from the object being cleansed. Carbon dioxide foams or froths used for fighting fires are formed from sodium bicarbonate and metallic salts: for example, aluminum sulphate.

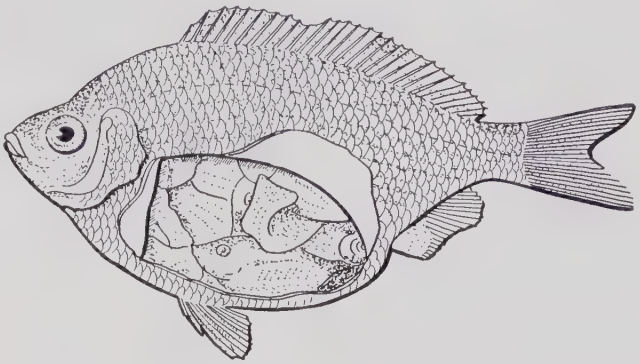
The adsorption of solids by liquids or by liquid films in foams is an important aspect of the industry of ore flotation and concentration. This is dependent on the development of agents that dissolve in the water and, at the same time, wet the solid surfaces to cause these to move with the liquid used, or to pass up into the foams that may be formed. The wetting agents used are specific for the mineral to be concentrated and are determined by the chemical nature of the mineral surface. *See also* Colloid Chemistry; Kinetic Theory and Statistical Mechanics; Lubrication; Precipitation, Electrical; Solids and Liquids, Theory of; Solutions, Chemical. H. S. T.

**SURFACE TENSION.** *See* Colloid Chemistry; Surface Phenomena.

**SURFBIRD,** a 10 in. wading bird, *Aphriza virgata,* allied to the turnstones. It breeds on high mountains of south central Alaska and winters on the Pacific coast of the Americas from Oregon to the Strait of Magellan. In winter it is brownish gray above and grayish white below. At all seasons it has a band of white along the extended wing and a broad terminal black band on the white tail. It may be seen on the coasts of the western United States, associated with turnstones, at rocky promontories, where it feeds on the barnacles and small mussels exposed at low tide. H. G. De.

**SURF CASTING.** *See* Fishing.

**SURF FISH,** small perchlike fishes of the family Embiotocidae, native to Pacific coastal areas, which give birth to rather large living young. The body is long and oval in shape and much compressed, ranging in length from 5 to 18 in. Some have red or blue stripes but most are silvery. Three species are found in Japan and the remaining 18 species are found only in California. They live in shallow coastal waters in bays or in the surf of sandy or rocky beaches. However, one lives in rather deep water and another, *Hysterocarpus traski,* lives in fresh-water streams of northern California. Mating occurs in late winter or early



*Surf fish,* Rhacochilus toxotes, *partially dissected to show the young*

summer and the living spermatozoa are carried in the female until late fall or early winter when the eggs are actually fertilized. The 8 to 18 or more young are retained in bags of fine tissue which are part of a modified oviduct and are bathed in nourishing body fluid. They are born the following spring or summer when about one inch long. Although esteemed by many anglers, surf fish are of minor commercial importance. E. C. R.

**SURGEONFISH, DOCTORFISH,** or **TANG,** a family, the Acanthuridae, of small-scaled compressed fishes found about coral reefs and tide pools in tropical seas. They are further distinguished by a sharp movable spine on each side of the tail base. These spines, which give the fish its common name, turn forward and into a sheath. When the fish is disturbed, the spines are erected, forming a dangerous weapon especially if grasped by the tail. About eighty species are known. Most of them are a soft gray-brown but some are bright blue and others have scarlet on the tail. Food consists largely of vegetable matter. The blue tang, *Acanthurus coeruleus,* of the West Indies area is common about Florida and sometimes strays northward to Cape Cod. The young are yellow and change to the blue phase when 5 or 6 in. long. The maximum length is about 1 ft. E. C. R.

**SURGERY,** that branch of medicine that treats diseases, disorders, malformations, and injuries wholly or partially by operative procedures. Surgery was practiced in very early times and prehistoric human remains indicate that surgery had attained a remarkable degree of competence. In historic times, and until the mid-eighteenth century, the surgeon was held in little esteem. Operations of considerable complexity were performed in Greece, Rome, India, and elsewhere in the ancient world, but, in general, surgery was considered an inferior branch of medicine. With the decline of learning in the Middle Ages the practice of surgery was delegated to barbers and wandering quacks. As Haggard points out, the reasons for the failure of surgery to develop fully were fourfold: a lack of anesthesia, an ignorance of the nature and control of infection, an ignorance of anatomy, and an inability to control hemorrhage. All but the most superficial surgery thus remained hazardous until comparatively

recent times. From the time of Vesalius (1514-1564), however, anatomical knowledge made great progress, and in the nineteenth century the development of anesthesis and the progress made in the field of antisepsis and asepsis based on the work of Pasteur, Lister, and others made possible the development of modern surgery. The subsequent use of X-rays in diagnosis and the discovery of increasingly effective controls for infection, coupled with great advances in surgical techniques, have brought about a remarkable decrease in surgical mortality, and the number of lives saved or prolonged by modern surgery is incalculable.

Modern surgery is divided into two types, namely, major and minor. This division is indicated by the extent of the procedure and may be illustrated as follows: incision of boils or carbuncles and suturing of cuts are classified as minor surgery; herniotomy and appendectomy are classed as major operations. Most minor operations are of short duration and are generally confined to the surface. Major operations have to do with the more vital organs and as a rule are of larger duration although they may vary greatly in the length of time required to perform the work. For example, an appendectomy may be performed sometimes in fifteen minutes, whereas the removal of a stomach requires from two to three hours and the removal of a pancreas may take as long as nine hours.

The technical name of an operation has a double meaning. The first part of the word applies to the organ and the last part to the procedure. For example, gastrectomy means removal of the stomach—gastric meaning stomach, and ectomy meaning removal. There are three such endings used in connection with operations on the organs of the body: ectomy, meaning removal; ostomy, to open and leave open; and otomy, to open and close; for example, gastrectomy, gastrostomy, and gastrotomy.

The medical student is both interested and astounded by the things that may be done to the human anatomy with little or no ill effect. He is convinced that we are fearfully and wonderfully made for the following reasons: some organs can be completely removed; some can be partially removed; and others can be short-circuited. Such operations are possible because nature has provided us with a great excess of certain types of tissue. We have eight times as much kidney tissue, seven times as much lung tissue, and ten times as much thyroid tissue as we need. Short-circuiting operations are made possible because other organs will take over the function of the ones that are short-circuited. For example, the ureters, which are the tubes that carry urine from the kidneys down to the bladder, can be transplanted into the large intestine and the bladder omitted. The liquid part is either absorbed or passed in the stool and the patient can live comfortably with no inconvenience. The large intestine can be removed and the small bowel allowed to open on the abdominal wall. The contents of this part of the intestine are ordinarily liquid. When so placed the contents become solid and the small intestine takes on the function of the large.

The following organs can be completely removed with no ill effect to the patient: the appendix, gall bladder, colon, stomach, spleen, and tonsils. Other organs can be partially removed, such as the brain, kidneys, thyroid, liver, pancreas, and lungs. Thyroid and pancreas can be completely removed with no ill effect to the patient, provided he is given substitution therapy.

General surgery is divided into subgroups, such as traumatic and nontraumatic surgery. The traumatic deals with conditions caused by an injury requiring surgery. The nontraumatic is concerned with infections, tumors, malformations and ulcers. General surgery can also be subdivided into septic and aseptic surgery, septic meaning due to an infection, and aseptic, not infected. An example of septic surgery is gas gangrene. An example of aseptic surgery is a thyroidectomy.

The more common bacteria encountered in surgery are the *Streptococci, Staphylococci,* and the bacteria found in the large intestine which are *Bacillus coli.* There are many different subgroups of these three. There are two other bacteria encountered, mainly in war surgery, which are known as the tetanus bacillus and the *Bacillus welchii.* The latter causes gas gangrene. The infections caused by the many strains of streptococci and staphylococci respond to the sulpha drugs and penicillin. The groups of bacteria found in the intestinal tract respond to treatment with streptomycin. This chemotherapy has made it possible to perform operations with much greater safety and has greatly decreased postoperative complications. It has become a source of encouragement and comfort to both the surgeon and the patient.

## OPERATIVE TECHNIQUE

**Surgical Instruments.** The modern operating room is equipped with many simple and complicated instruments and apparatuses. There are certain basic ones required for any operation, such as hemostats (clamps required in grasping blood vessels), scalpels (knives), needles, needle holders, sponge sticks, thumb forceps, scissors, and various retractors. Each type of major surgery requires many special instruments as well as the basic ones. For instance, it would be impossible to perform a spinal fusion with the same instruments that are required for the removal of a gall bladder. These special instruments are so shaped and designed as to facilitate the surgeon's technique, thereby making the procedure easier for both the surgeon and the patient. Special lights are necessary so that the surgeon can see what he is doing. They must be bright, adjustable, and must not throw shadows.

**Preparation of the Skin.** The first and most important step is the proper cleansing of the skin. All hair-bearing areas should be carefully shaved. They should then be cleansed with soap and water and dried with ether. Antiseptic solutions such as iodine are then applied. At best only the surface bacteria are inactivated by antiseptics and not the ones in the glands or hair follicles of the skin. Consequently, the cleansing with soap and water is the most important single procedure, since this cleanses and removes most of the bacteria on the surface.

**Types of Incisions.** Incisions can be made with a knife or with an electrocautery. The advantages of the latter are that it reduces bleeding and, if dealing with cancer, closes off the lymphatics and reduces the spread of the tumor cells.

**Locations.** The choice of incision is influenced by its proximity to the organ upon which the operation is to be performed and also by the structures through which the surgeon must go to reach the organ which is to be removed. The surgeon must avoid cutting vital structures. For instance, the easiest approach to the hip joint would be to make an incision in the groin and go directly through the tissues encountered, but these tissues would include the main blood vessel to the leg and an important nerve which serves the thigh. Consequently, such an incision would be impractical. Most surgeons prefer muscle-separating operations to muscle-cutting ones. An example of muscle-separation is the McBurney incision for an appendectomy. The muscle-cutting incision cuts transversely across the muscle fibers and is always employed in the removal of the spleen. These incisions are more difficult to close. Moreover,

if a rupture should occur in such a wound, it is most difficult to repair.

**Hemostasis.** This concerns the control of bleeding. It is most important for the patient and also for the surgeon. Blood loss is the most common cause of shock. Patients can be operated on for eight or ten hours without showing signs of shock provided no blood is lost. In most cases the amount of blood lost should be very small if the surgeon will take the time and trouble to clamp and then tie off all bleeders with a ligature. It is important to have a dry operating field so that the surgeon can see the anatomical structures. Sometimes it is impossible to avoid a certain amount of blood loss. In these cases the operative field is kept dry by sponging or absorbing the blood with gauze pads. Suction is also used for the same purpose.

**Retraction.** This is the separation of the incision with instruments called retractors. All tissues, especially muscles, become approximated if left alone. It is necessary that the surgeon see clearly what he is doing; consequently, retraction of the wound is extremely important and the patient must be properly relaxed with an anesthetic to accomplish this act. There are many different retractors in use. Some are named according to their shape, as the rake retractor or right-angle retractor, others according to their purpose, as the self-retaining retractor, and others are named by their designer. The retraction is usually done by an assistant.

**Sutures.** After having anesthetized the patient, prepared the skin, made the incision, controlled the bleeding, and removed the pathology, the defect is repaired by sutures.

*Suture Material.* There are three types of suture, namely absorbable, nonabsorbable, and living sutures. The absorbable sutures are plain and chromic catgut. The term catgut is a misnomer for they are actually made from sheep intestines. Sutures vary greatly in size and strength. The chromic sutures are treated chemically and are more resistant to tissue absorption. They remain in the tissues from 10 to 40 days. Plain catgut is absorbed more rapidly. Catgut is a tissue irritant and it is this irritation which causes a tissue reaction resulting in ultimate absorption. There are four main types of nonabsorbable sutures, namely, silk, cotton, silver wire, and vitallium wire. Even though these sutures are not absorbed they remain in the tissues for years, causing no discomfort. These sutures are used only in clean wounds which have weak tissues, as in a hernia. They remain in place indefinitely. Living sutures, which are usually obtained from a firm layer of tissue which surrounds the thigh muscles, the fascia lata, become part of the tissue in which they are placed. Blood vessels grow into them from the surrounding tissues and they become part of the living tissues.

*Needles.* Sutures are placed in the tissues with needles. These needles vary greatly in size depending on the size of the suture material used and the delicacy of the tissues through which they are passed. For instance, very fine ones are used in eye operations and large ones for the approximation of fat layers in wounds. Needles have round edges and cutting edges. The latter are used in tough tissues such as skin. The cutting edges extend back from the point about one third of the length of the needle and as it passes through the tissues it cuts its way, thus facilitating its passing. The round edge needles are used in softer tissues as muscles and fat. Needles may be straight or curved. The curved may have a full curve, shaped like a circle, or a half curve. The straight needles are held in the fingers, whereas the curved type is used with a needleholder which helps to control it and enables the surgeon to force it through the tissues.

**Drains and Dressing.** Drains are generally of some type of rubber tubing which can be removed easily without sticking to the tissues and causing too much pain. They are used in wounds where pus is encountered, as in an abdominal abscess, or where a collection of serum may form after the incision is closed. A fairly large dressing is applied, in the form of sterile gauze pads, to cover the wound, and this is held in place with adhesive.

**Postoperative Care.** Patients are given from one sixth to one quarter of a grain of morphine or its derivatives every four hours, if necessary, to control the pain. The pain usually subsides by the second or third day and can be controlled then by milder sedatives. The skin sutures or clips are removed generally between the seventh and the ninth day after operation.

**Wound Healing.** This begins very quickly and the average wound is quite firm by the twelfth to the fourteenth day. Healing is retarded by infection, collection of serum in wounds, lack of vitamin C, and low protein content in the blood. Infections retard or may even prevent wound healing; this may be easily controlled by such drugs as sulphadiazine, penicillin, or streptomycin. Experiments have proved that vitamins, especially vitamin C, and blood proteins hasten the process of wound healing. Anemia does not in itself affect wound healing.

**Surgical Risks.** Surgical risks affect the chance the patient has of recovering from the surgical procedure. They are not related to the end results except insofar as the patient's immediate chances of withstanding the operation are concerned. Such risks are classified as good, poor, and bad. They are influenced by infection as peritonitis, diseased kidneys (nephritis), diseased lungs (tuberculosis), conditions of the heart (as coronary occlusion, valvular disease, and decompensation of the heart), imbalances in blood chemistries (as hypoproteinemia, decreased amount of protein in the blood), dehydration, anemia, and avitaminosis. Age and weight influence surgical risks to a minor degree. Young babies withstand intestinal resections very poorly. Old people, however, withstand surgery very well provided their condition is not jeopardized by any of the above complications. Adipose (fat) patients are not as good surgical risks as thin patients due to the fact that they require more anesthesia, and the surgical procedures are more difficult to perform because of the poor exposure and the thick layers of tissue through which the surgeon has to work. Fat gets on the surgeon's gloves, making steps such as placing and tying ligatures more difficult. Many of the conditions mentioned previously, as tuberculosis of the lungs and cardiac conditions, can be partly overcome by the proper use of anesthesias. *See also* ANESTHESIA. W. H. B.

## NOSE AND THROAT SURGERY

Although many conditions of the nose and throat are effectively and adequately treated by purely medical means, some diseases of this area demand operations for their proper relief. Operations on the nose include those performed for cosmetic reasons, for the improvement of breathing space, for the proper drainage of infections in the sinuses, and for the removal of tumors and foreign bodies. In the throat, operations are needed for the removal of infected tonsils and adenoids, and of tumors, both benign and malignant. Operations are also needed for the relief of mechanical asphyxia in cases of obstruction by inflammation, tumors, or foreign bodies.

**Plastic Repairs.** One of man's earliest known reasons for consulting the surgeon was the desire to change the shape of his nose. The misshapen nose may be cosmetically un-

desirable without seriously hampering the respiratory function, but it may be of great medical importance by being psychologically harmful.

One of the chief difficulties of nasal plastic surgery is the fact that radical changes have to be made in the deeper structures without scarring the skin. Extensive operations can be performed on the bridge of the nose by incisions made in the lining, instruments being inserted through the nostrils. Rasps and files are introduced in this way to lower a hump in the bone. Pieces of cartilage taken from the ribs can be grafted into the bridge through this approach. Molds are made of dental plaster or soft metal to hold the nose in the desired form while it heals. Severe nasal deformities require external surgery. For example, if the nose is very small or absent, it can be constructed by bone, cartilage, and skin grafts or by the application of artificial appliances to simulate the shape of the natural nose. Such extreme deformities may be present at birth or may result from accidental or war injury.

**Repairs of Sinuses.** Internal nasal operations are done either for the relief of obstruction or for improvement in the drainage of the sinuses. When the natural drainage of a sinus is prevented by an obstruction in its tiny opening or in the nose, painful and even dangerous sinus disease may result. Such obstruction could be brought about by deformity of the inner structure of the nose, from improper development, or from injury, or by swelling associated with infection, or by the presence of polyps, tumors, or foreign bodies. The treatment of these conditions must often be surgical. The operations are performed by means of long instruments inserted through the nostrils.

**Radical Operations.** Tumors, cancer, or severe chronic infection may call for radical operations, such as the removal of the entire lining of one or more sinuses. In these cases, the surgical approach is made either from the mouth into a sinus, or else through the skin of the face. Scars carefully placed in the natural creases of the face may go almost unnoticed. A radical operation of the frontal sinuses, which are situated just above the eyes, may result in the depression of the forehead. Various methods of plastic reconstruction are used, such as bone or cartilage grafts, or of artificial supports.

**Tonsils and Adenoids.** Throat operations are complicated by the fact that several vital structures are found in the neck, including the food and air passages and some important vessels and nerves. Damage to these structures may have serious consequences. Above all, the airway to the lungs must be kept open at all costs, a factor which requires constant vigilance during an operation so as to avoid obstruction by pressure, mucus, or blood. In tonsilectomy and adenoidectomy, the patient is placed in a head-low position so that blood and saliva are kept in the upper throat by gravity, and constant cleansing, effected by use of a suction pump, is maintained during the operation. The tonsils are accessible with long instruments passed through the mouth. The adenoids are located on a level higher than the soft palate. They are removed with cutting instruments angulated to reach upward.

**Cancer of Throat.** Cancer of the throat is a disease challenging the ingenuity of both surgeon and patient. In many cases it is necessary to remove the entire larynx or "voice box," the patient breathing through a permanent opening made in the lower part of the front of the neck.

**Tracheotomy.** One of the most alarming conditions ever to confront the physician is obstruction of the throat by swelling, tumor, or foreign bodies. When the obstruction is complete, it is with desperate urgency that the patient must be provided with an airway to the lungs or death will supervene in a few minutes. An incision is made in the front of the neck. The trachea, or "wind pipe" is opened, and a silver tube is inserted to admit air. This operation, known as tracheotomy, is usually performed before the obstruction becomes complete, since the majority of such cases are not abrupt in onset.

**Foreign Bodies.** Foreign bodies in the air and food passages are usually removed by the insertion of illuminated metal tubes, such as the bronchoscope and esophagoscope, through the mouth into the passageway involved. Foreign bodies may be such objects as fish bones, chicken bones, peanuts, straight pins, safety pins, needles, tacks, buttons, or coins. Special long-handled forceps have been designed for grasping different types of foreign bodies. For example, there are instruments for closing a safety pin while it is still down in the throat. The removal of foreign bodies is aided by x-ray films or by the bi-plane fluoroscope. *See also* EAR (*Ear Surgery*); EYE (*Eye Surgery*). R. C. M.

## THORACIC SURGERY

**Surgery of the Lungs.** Most surgery of the lungs is undertaken in the treatment of tuberculosis. One of the main factors responsible for the lowering of tuberculosis mortality has been the pneumothorax operation. By this procedure air is injected into the pleural cavity surrounding the lung; the lung is thus made to collapse since the negative pressure in the pleural cavity which prevents it from doing so is released, and in this quiescent state the tuberculous lesions in the lung are enabled to heal more effectively. In the event that tuberculous adhesions prevent the collapse of the lung by a pneumothorax, a more radical operation, thoracoplasty, may be undertaken. This involves the removal of the ribs covering the affected portions of the lung and produces a permanent collapse of the chest wall over the diseased area. This collapse of the lung can also be effected by a paralysis of the portion of the diaphragm under the affected lung, or, in the case of adhesions, an operation, intrapleural pneumolysis, has been developed by which the adhesions may be divided by means of a small cautery. Thoracoplasty is used in cases where the lung is so diseased that even a long period of collapse would not serve to restore the function of the lung tissue.

The most radical operation on the lung is the resection or removal of the diseased areas. This operation is indicated in cases of cancer of the lung, in cases of tuberculosis where the lung tissue has been damaged beyond recovery, in lung abscesses, in cases involving gangrene, or in cases of bronchiectasis, where portions of the bronchi have become distended and inelastic and therefore cannot be drained of infection by the normal process of coughing.

**Surgery of the Pleura.** Empyema, or pus, in the pleural cavity was well recognized by Hippocrates, who recognized the good results of draining such an abscess. At the present time early empyema is best aspirated with a syringe and needle until it becomes thick, after which it becomes necessary to drain it. Chronic empyema heals with difficulty. The cure of tuberculous empyema is to bring the two surfaces of pleura together and allow the space to be obliterated.

**Surgery of the Heart.** The hazards of performing surgery on the heart did not prevent early investigators from undertaking it. In 1897 Rehn first successfully sutured a stab wound of the heart in man, and other early surgery included decortication for a condition in which the heart is encased and constricted by a thick plaque of fibrous tissue. Another early example of heart surgery involved an operation

on the heart valves to overcome the narrowing that occurred when the valve had been affected by disease.

Various congenital heart defects in children have been corrected by surgery. In the condition known as patent ductus arteriosus, the blood circulation of the fetus transporting blood from the right side of the heart to the general circulation without traversing the lung tends to persist instead of changing normally at birth, when the ductus arteriosus regularly tends to close. For such cases, an operation has been developed to tie off this vessel. In the case of coarctation, a congenital narrowing of the aorta, an operation is possible to resect the narrowed portion and establish a normal flow of blood. Another congenital defect of the heart is pulmonary stenosis, where the pulmonic valve connecting the right ventricle with the pulmonary artery is narrowed and prevents or slows the flow of blood to the lungs; in addition a communication between the ventricles shunts the blood from the right to the left side and into the general circulation without going through the lungs. Such a condition has been ameliorated by surgically establishing a communication between the general circulation and the pulmonary artery. This operation does not completely rectify the inadequacy, but it enables a child to lead a fairly normal existence.

Further operations on the heart are limited by the fact that the supply of aerated blood to the brain must not be cut off for more than five to seven minutes. For this reason attempts have been made to aerate the blood outside of the body and return it to the head, thus permitting more extensive surgery without the heart having to fulfill its function of supplying the brain with blood. In spite of this time limitation, however, a certain amount of intracardiac work has been performed, such as attempts to close patent interventricular septa and direct surgery on the mitral valve. Experimental operations in cases of coronary thrombosis, where the blood supply nourishing the heart itself is reduced, have also been attempted to replenish the blood supply of the heart from adjacent tissues.

**Other Thoracic Surgery.** In cases where the esophagus must be removed, a technique has been developed whereby the stomach is brought up into the chest, care being taken to preserve its blood supply, and to connect it to the upper end of the esophagus. Surgical treatment is also possible for cases of diaphragmatic hernia or injury, and operations on the sympathetic nerves for high blood pressure in cases that have a spastic type of hypertension have been successfully performed intrathoracically. The removal of the thymus gland, when it is involved in a tumor or a cyst, is sometimes indicated, and this operation will also lessen the severity of myesthenia gravis, a disease characterized by severe muscular weakness. Further thoracic operations include the removal of tumors in the mediastinum, such as lipomas, dermoid cysts, bronchial cysts, neurofibromas, pericardial cysts, and a variety of others.

## ABDOMINAL SURGERY

Abdominal surgery is the general term for surgery performed on various abdominal viscera, such as the stomach, the intestines, the liver, the gall bladder, the pancreas, and the spleen.

**Gastrointestinal Surgery.** Gastrointestinal surgery comprises the largest portion of the general surgeon's work. It includes the stomach; the small intestine, comprised of the duodenum, the jejunum, and the ileum; and the colon, comprised of the caecum, the ascending colon, the transverse colon, the descending colon, the sigmoid flexure, and the rectum. The pathology differs in different parts of the intestine, and each organ must therefore be dealt with separately.

*Surgery of the Stomach.* The conditions of the stomach requiring surgery are ulcers, tumors, gunshot wounds, and foreign bodies. Ulcers, which produce defects of the lining of the stomach, may be treated by a diet that will produce decreased acidity in the stomach, but if this treatment proves ineffective surgery is indicated. The operation of choice is a subtotal gastrectomy, removing the lower half or two thirds of the stomach and attaching the open end of the stomach to the side of the small intestine. A more recently developed operation cuts the vagi nerves just as they come through the opening in the diaphragm. Since these nerves regulate the secretion of acid in the stomach, cutting them will allow the ulcer to heal. Sometimes ulcers perforate the stomach wall and admit the acid contents of the stomach into the abdominal cavity. The treatment is an immediate operation to locate and close the perforation.

Other conditions requiring surgery of the stomach are carcinoma of the stomach, which calls for a subtotal gastrectomy to resect the affected areas; the presence of foreign bodies, which may be removed by gastrotomy; gastric hemorrhage, caused by cancer, ulcers, or varicose veins, which may require subtotal gastrectomy; and pyloric stenosis. In pyloric stenosis, a condition found in newborn babies, the sphincter of the stomach at the exit, or pylorus, is greatly thickened and hypertrophied. The abdomen is opened and an incision is made down through the muscle of the sphincter, but not through the mucous membrane. The patients generally recover.

*Duodenal Surgery.* Pathological conditions in the duodenum differ considerably from those in the stomach. Duodenal cancer is extremely rare, but duodenal ulcers are even more frequent than those of the stomach; as in the cases of carcinoma of the stomach and gastric ulcers, the incidence of duodenal ulcers is several times higher in men than in women. If surgical treatment is indicated, a subtotal gastrectomy is performed with the removal of the duodenal ulcer if possible.

*Small Intestine Surgery.* The main indication for surgery of the small intestine is intestinal obstruction. Obstructions may be caused by adhesions, characterized by the formation of bands of connective tissue and generally caused by operations or inflammatory processes; strictures, caused by new growths or inflammation, or present congenitally; hernias, into which a portion of the intestine may work itself and become constricted; volvulus, or the rotation of loops of the intestine upon themselves; intussusception, where the intestine has become telescoped; or paralytic ileus, caused by an overactive sympathetic nervous system which inhibits the peristalsis of the intestine. If the obstruction is complete, an operation should be performed at once and the cause removed. Sometimes Meckel's diverticulum, a congenital pouch on the side of the small intestine, becomes inflamed, producing the same symptoms as appendicitis; it must then be removed and the opening into the intestine closed. Cancer seldom occurs in the small intestine, except at the exit of the pancreatic duct and bile duct.

*Surgery of the Colon.* Conditions of the large intestine requiring surgery are cancer, polyps, intestinal obstructions, and certain forms of colitis. Carcinoma of the colon is common, particularly at the sigmoid flexure; the growth with its glands must be removed and the two ends of the colon anastomosed. If obstruction is present, a colostomy is performed; a loop of colon is brought out on the abdomen, opened, and allowed to drain. The anastomosis is done at a

later date and the colostomy closed. If the rectum is involved, it must be removed entirely and a permanent colostomy performed. The patient's bowels then move on the abdomen. This is cared for and controlled by a special colostomy bag fitted over the opening.

Other conditions calling for surgery of the colon are polyps and ulcerative colitis. Polyps are small masses of tissue covered by mucous membrane and generally attached to the intestinal wall by a narrow pedicle; they should be removed locally, for a high percentage of them become malignant. Ulcerative colitis is caused by an enterococcus or the organisms that cause dysentery; it may also be caused by food allergies. If the symptoms last over three years, an ileostomy should be performed. The distal part of the small intestine is detached from the colon, brought out to the surface of the abdomen, and allowed to empty there. This gives the infection a chance to subside by putting the colon at rest. When the ileum is functioning properly, the entire colon is removed and the patient is fitted with a colostomy bag.

**Surgery of the Liver.** Higher animals cannot survive without the liver. Complete removal of the liver is usually followed by death within two to three days. Surgery of the liver is performed in cases of traumatic injuries, abscesses, cysts, and tumors. Because of its size and consistency, the liver is easily injured. Consequently, liver injuries result in a major portion of the operations performed on the organ. These injuries are of two types: those caused by gunshot wounds and stab wounds, and those caused by blows and kicks over the liver by compression or crushing, or resulting from jack-knifing, a sharp bending of the body. This latter occurs sometimes in newborn babies where the so-called jack-knifing is used to start the baby breathing. Cases of spontaneous rupture have also been reported.

Regardless of the cause, the symptoms are the same. The liver has a rich blood supply, and many bile ducts. Consequently, an opening into its substance will allow the escape of these two fluids into the abdomen, causing irritation of the peritoneum; the patient, therefore, complains of severe pain in the abdomen, and the irritation causes the abdominal muscles to become very tense and sensitive to pressure. If the bleeding is severe, the patient will show signs of shock, which is manifested by a rapid pulse and a falling blood pressure.

If the signs of abdominal irritation are present, or if the patient is showing signs of shock, the abdomen should be opened, the blood and bile removed, the wound in the liver sutured, if possible, and, if not possible, packed, and the abdomen drained. Penicillin should be given in gunshot wounds to prevent the formation of an abscess. During World War II, it was observed that many liver injuries would close spontaneously and did not require a laparotomy, or incision of the abdominal wall.

Liver abscesses may be caused by bacteria or by parasites, such as amoebas. The abscesses may be single or multiple, large or small. Treatment involves opening and draining the abscesses without contaminating the abdominal cavity. Abscesses caused by an organism known as the *Endoamoeba hystolytica* are sterile and do not contain organisms that form pus. Therefore, they are aspirated, and the patient is given a drug called emetine.

Development of a larval stage of the tapeworm, *Taenia echinococcus,* causes cysts of the liver. The adult form of this tapeworm is found in dogs and other canines. The cyst, and also its lining and daughter cells, must be removed intact; otherwise it will merely re-form in such locations as may become contaminated.

Benign or nonmalignant tumors are found in the liver, but are rather uncommon. Malignant ones are found much more frequently. They usually start in other parts of the body and spread to the liver, although occasionally they may originate in the liver. Since 1940, attempts have been made to remove the part involved, but the results are questionable. Treatment is most unsatisfactory.

W. H. B. and W. T. G.

**Gall Bladder and Bile Duct Surgery.** The external secretion of the liver is bile and it empties into the duodenum or first portion of the small intestine via the bile ducts. There are two ducts which emerge from the liver and unite to form one duct. This one is joined by another duct from the gall bladder forming the common duct which empties into the intestines. The gall bladder is a pear-shaped organ situated on the under surface of the liver and contains from 30 to 40 cc. of bile. There are certain pathological conditions of the gall bladder which require treatment by surgery, such as gall stones and inflammatory conditions.

There are many theories as to the cause of gall stones. Infection, metabolic disturbances, and stasis of the bile are the three most probable causes. Gall stones may be 2 to 3 in. in diameter or as small as fine gravel. They may be single or number as many as 4 to 500. Most inflammations of the gall bladder are associated with the presence of stones. Sometimes one of these smaller stones works its way down into the ducts, causing excruciating pain, with nausea and vomiting. If the stone becomes lodged in the common duct, no bile can get into the intestine. The back pressure is so great that the bile gets into the blood system and all the tissues become yellow or jaundiced. The stone may become lodged at the exit of the gall bladder. Frequently either the gall bladder or bile ducts will become infected following the lodging of such a stone. If the patient is a good surgical risk, the treatment of choice is the removal of the gall bladder and cystic duct. Most stones, sooner or later, cause trouble and the only way to avoid this is to remove the organ. This procedure is called a cholecystectomy. If the stones are removed and the gall bladder allowed to remain, stones are apt to reform. When they become lodged in the common duct and the patient becomes jaundiced, surgical intervention is necessary. Occasionally these stones will pass, but if the jaundice increases or remains constant after a period of four to seven days an operation is justified. This operation, which consists of opening the common bile duct, removing the stone and inserting a tube, is called a choledochostomy.

Inflammation or cholecystitis may occur in a gall bladder without stones, but more frequently with stones. The infecting organisms are often those of the intestine, such as the colon bacillus group. In some cases of typhoid carriers, or people who have had typhoid, the typhoid germs may be found in the gall bladder for many years after the original infection.

Sometimes the gall bladder may rupture and cause either a localized abscess or a peritonitis. There are two distinct schools of thought on the treatment. One is to operate as soon as the diagnosis is established and the other is to wait operation until the infection has entirely subsided. In either case the gall bladder should be removed.

**Pancreatic Surgery.** Acute pancreatitis, chronic pancreatitis, pancreatic calculi, pancreatic cysts, and cancer of the pancreas all require surgical intervention. Wounds of the pancreas are classified under two types, gunshot or stab wounds. The treatment is to open the upper abdomen and either suture with silk or pack with gauze. Silk should be

used instead of catgut because the latter is destroyed by the pancreatic enzymes. A drain should always be placed down to the wound in the organ.

There are two schools of thought on the treatment of acute pancreatitis. One is to operate—the other is to treat the patient supportatively by administering saline and glucose intravenously, and by chemotherapy. In the treatment of chronic pancreatitis surgery is undertaken to remove the cause, such as an infected gall bladder or obstruction to the ducts.

Pancreatic stones caused by stasis in the flow of the secretion plus infection should be removed, if possible, but sometimes the calculi are so extensive that the gland itself has to be removed. Cysts of the pancreas are rather rare. Retention and hemorrhagic cysts are more common than hydatid cysts, which are caused by the dog tapeworm. The cyst should be completely removed. Sometimes this is impossible and the cyst wall must be sutured to an opening in the abdominal wall and allowed to drain. This is known as marsupialization. The lining of the sac can then be cauterized at a later date.

Nothing is known of the cause of pancreatic cancer. The tumor is nearly always found in the head which is the part of the gland closely attached to the intestine. The only way the diagnosis can be established is by biopsy. The treatment is one of the most difficult of all surgical procedures. The head of the gland is removed with the portion of the adjoining small intestine. The bile duct is reattached to the intestine and the intestine to the stomach. Sometimes the entire gland is removed. Prognosis of this condition is generally poor.

**Spleen Surgery.** The function of the spleen is to form certain types of white blood cells and blood platelets, to destroy red blood cells, and to store blood. In spite of all these functions, the spleen can be removed with no ill effects to the patient. The following conditions are benefited by surgery: (1) rupture of the spleen; (2) torsion; (3) hemolytic jaundice; (4) thrombocytopenic purpura; (5) Banti's syndrome; and (6) enlarged spleens which cause mechanical distress in which splenectomy (removal of the spleen) is not contraindicated. Gaucher's disease and sickle cell anemia have been treated surgically with questionable benefit.

The spleen is a fairly delicate organ, and in spite of the protection given it by the lower ribs it is sometimes ruptured in accidents. The bleeding may occur at once, or may be delayed for many months. Spontaneous ruptures also occur. The patient should be transfused, and the spleen removed as soon as the diagnosis is established.

Hemolytic jaundice, the result of an inherited defect of the red blood cells, calls for removal of the spleen, as does thrombocytopenic purpura. If Banti's syndrome is diagnosed early, removal of the spleen gives good results; otherwise, surgery is of no value. The spleen is removed through a muscle-cutting incision along the left costal margin.

Gaucher's disease is an inherited disease which disturbs the fat metabolism and is associated with increased size of the spleen. The spleen may be removed surgically, but the results are not entirely satisfactory. Sickle cell anemia is found generally in Negroes, and is characterized by both anemia and splenic enlargement. The value of splenectomy in sickle cell anemia is open to question. W. H. B.

## NEUROLOGICAL SURGERY

Neurological surgery is concerned with the diagnosis and treatment of diseases of the brain, spinal cord, peripheral nerves, and sympathetic nervous system. The neurological surgeon must be neurologist as well as surgeon. The brain and spinal cord are delicate structures which suffer great penalties if they are not carefully treated. Generally, it has been found impracticable to explore the cranium surgically, as, for example, the abdomen is explored, and practice requires exact information concerning the location, extent, and nature of a disease before neurosurgical treatment is undertaken. Technical developments, including anesthesia and asepsis, are also important factors in surgical treatment of the nervous system. The successful penetration of the brain barrier requires such exacting and laborious effort that the mere safe exposure of the brain may occupy more time than that required for complete major operations in more accessible parts of the body.

**Diagnostic Development.** Modern neurological surgery began in the latter half of the nineteenth century, when great strides were made in the collection of data concerning the anatomy, physiology, and pathology of the nervous system. Pioneers in the field used this information to interpret the complaints and abnormalities of their patients and to identify and localize the diseases producing these complaints. However, the body, even the brain, often responds in a similar manner to many afflictions and may endure extensive lesions with little obvious change. For a precise diagnosis, more information was needed than could be obtained by the clinical approach, and this, in turn, required refinements of the methods of acquiring information.

Pneumography, introduced in 1918 by Dr. Walter Dandy at Johns Hopkins University, was among the first of these developments. In pneumography, the cerebrospinal fluid is replaced by some gas, such as air or oxygen, following which X-ray films of the head are taken to show the location and conformation of the gas within the cranium. If the pressure is normal, the exchange may be carried out through needles inserted into the spaces of the lumbar spine (encephalography). If the intracranial pressure is elevated, the exchange is made directly by introducing needles into the cavities within the brain (ventricles) through small openings made in the skull (ventriculography). This single procedure has contributed greatly toward the localization of a disease and in a lesser degree, toward its identification.

Another refinement was the visualization of the intracranial arteries and veins of the brain, again through the medium of the X-ray film. This procedure, known as angiography, was introduced in 1927 by Egaz Moniz, of Lisbon, Portugal. A substance which blocks the passage of X rays (radiopaque substance) is injected into one of the arteries leading to the brain; X-ray films are then made in rapid succession, recording its passage through the arteries (arteriogram) and veins (venogram). Abnormalities of the blood vessels or distortion of their course or distribution can be shown by this means.

Electroencephalography, a study of the electrical activity of the brain by an electronic device, has shown promise since its introduction in 1929.

In the spine, plain X-ray films are valuable in the recognition of skeletal alterations. The localization of tumors and other distortive processes in the spine has been facilitated since 1922, when Sicard and Forrestier, of Paris, showed that certain oily substances containing radiopaque elements could be introduced safely into the spinal canal. After injection, the material can be moved up and down the canal by tilting the patient, and its position can be recorded by means of the X ray (myelography).

**Tumor Surgery.** Tumors or new growths affecting the brain were among the first brain diseases to be treated by

surgery. These tumors may destroy the brain by invading it, paralyze some function of it through focal compression, or irritate it and cause convulsions. Mentality is seldom seriously impaired by brain tumors.

Of all the cranial nerves, the auditory is most commonly affected by tumors. Because of its location, it is extremely difficult to remove all the tumor from its attachment to the highly vulnerable brain stem. The nerve of motion of the face usually lies within the capsule of this tumor and facial paralysis is a complication frequently associated with successful radical removal.

Tumors in the cerebrum are usually reached by reflecting a "flap" of the scalp and by elevating an area of the skull suitable in size and location (osteoplastic craniotomy). The dura mater is then cut, and the brain, covered only by the arachnoid, is exposed. At the end of the operation, the dura mater is closed and the block of skull and the scalp are replaced. The bone beneath the temporal muscle may be removed safely and not replaced, giving some added volume to the cranial cavity. This procedure is called "decompression." When a tumor, such as a meningioma, has invaded the skull, it is sometimes wise not to replace the affected bone, but, instead to cover the exposed area with an inert metal or plastic plate shaped to fit. Similar repair of defects in the skull may be necessary after extensive head injuries.

The cerebellum is usually approached by reflecting the heavy muscles at the back of the neck and by removing sufficient bone to expose the region desired. This bone is not replaced as a rule, the muscles affording sufficient protection to the underlying structures (myoplastic craniectomy).

The spinal cord and its coverings come from the same embryonic source as the brain. Gliomas invade it and usually are not removable. However, the encapsulated tumors of its meninges and nerves which may compress it can be completely removed, and, when found early, have a good prognosis.

A lesion which acts as a tumor of the spinal canal but which is not a new growth is the protrusion into the canal of material from the intervertebral discs, a plate of cartilage and fibrous tissue lying between successive vertebrae. It degenerates with age and may be partly extruded into the spinal canal in such a way that the spinal roots are irritated and produce pain. The low lumbar region is most commonly affected and involvement of the lower cervical region is next in frequency of occurrence. The pain resulting from this irritation is generally relieved by removal of the offending tissue.

**Surgical Treatment of Injuries.** Injury of the nervous system has increased in frequency and severity with the development of mechanical aids to man's movements and productivity.

*Brain Injuries.* The brain may be damaged when the skull is penetrated by a missile, as in a bullet wound, or when the body is thrown against relatively resistant objects, as in a fall or an automobile accident. A penetrating missile causes laceration of the brain, with the resultant hemorrhage producing secondary damage. Bullets are usually sterile, but other penetrating bodies may carry infection themselves. If the head has been thrown against a resistant object, there may be concussion, a state in which there is transitory paralysis of function but no demonstrable permanent change in the brain. The brain may be contused or bruised, which will leave some scar tissue. If the skull is fractured and the overlying scalp lacerated, the wound is said to be compounded and is open to possible infection.

*Subdural Hematoma.* Injury to the head, even of slight degree, may rupture blood vessels, producing damage to the brain by the pressure and destructive effect of accumulated blood between the dura mater and the arachnoid. In this case, as it disintegrates it attracts fluid by osmosis, and the resulting subdural hematoma will produce symptoms as it increases in size. Hematomas within the brain are less common. Most intracranial hematomas can be drained satisfactorily through small openings, although occasionally a large exposure is necessary.

*Spinal Cord Injuries.* The spinal cord also is subject to concussion, contusion, compression, or laceration. Here, too, injury may be complicated by hemorrhage or infection. Compression, as by a blod clot or by bone, may be relieved by laminectomy, but laceration and contusion usually are not benefited by surgical methods.

*Injuries to Peripheral Nerves.* The peripheral nerves also may be lacerated, as by glass, knife or missile, or by the sharp edges of adjacent broken bones. The nerves outside of the cranium and spinal canal will regenerate with varying degrees of return of function if the ends of the nerve can be brought together. Bruised nerves or those compressed, as by scar tissue, may have their function impaired or may become extremely sensitive. The interruption of this binding scar tissue (neurolysis) often may be of benefit.

Sometimes nerves lie where they receive slight but repeated injuries. In such cases, in addition to neurolysis, it may be necessary to shift the nerve to a less vulnerable part of the extremity.

**Brain Abscesses.** Brain abscesses are treated by draining the pus and preventing its reaccumulation, and by keeping the intracranial pressure as nearly as possible within normal limits. An abscess which has formed a capsule may occasionally be completely removed in the same manner as a tumor.

The tissues about the spinal cord are particularly susceptible to infection from the skin and the lungs. Abscess here can be drained by laminectomy, relieving the pressure upon the cord. Abscess within the cord can be drained, but significant improvement is rare.

**Brain Hemorrhage.** Many instances of spontaneous brain hemorrhage are found to result from congenital weakness in the walls of blood vessels of the brain. These weak spots allow a thin sac to protrude from the blood vessel wall. The sac is called an aneurysm. This may rupture with symptoms varying from slight headache to death. It is possible sometimes to ligate the blood vessel, thus removing the danger of rupture.

**Psycho-Surgery.** Certain of the insanities appear to be favorably affected by the operation of frontal lobotomy or leukotomy, in which the fiber pathways connecting the frontal lobe of the brain with the remainder are severed. This operation, first described in 1935 by Egaz Moniz, has been used in selected cases with promising results.

**Surgery of Epilepsy.** Certain types of convulsive seizures are the result of irritation from the scars of the brain caused by injuries. Removal of such a scar may result in reduction or elimination of the seizures. The results in carefully selected cases have been promising. Most convulsive states are not due to conditions amenable to surgery.

**Relief of Pain.** Man is afflicted by many diseases which continue to defy the physician's efforts at treatment. Pain is a major manifestation of some of these—so much so that, from the point of view of the sufferer, anything, even numbness, is desirable by comparison. The nerve supplying sensation to the face is subject to a painful condition of uncertain

origin known as trigeminal neuralgia or *tic douloureux*. The pain can be relieved temporarily by injecting the nerve with alcohol, or permanently by cutting the nerve near the brain stem. Similar pain in the throat (glossopharyngeal neuralgia) can be helped by spraying with a local anesthetic or by cutting the nerve, again near the brain stem.

Pain elsewhere, resulting from incurable diseases, may be helped by deliberately cutting the pathway for pain in the spinal cord. This operation, cordotomy, preserves all sensations but pain and temperature appreciation and is particularly adapted to relief of pain in the lower part of the body. When cordotomy is not suitable, it may be necessary to cut the sensory nerves to an area and produce complete numbness. Sometimes any surgery is unwise and alcohol can be injected into the spine, giving some transitory relief, although often with undesirable side effects.

**Sympathetic Neurological Surgery.** The sympathetic nervous system may carry impulses related to pain, especially that associated with injury to peripheral nerves and to blood vessels. Injection of local anesthetic into the vicinity of the related sympathetic chain of ganglia, or their surgical removal (sympathectomy), may be required to obtain suitable relief. Only a few diseases can be treated successfully by this method. Among those giving some promise of being aided is arterial hypertension, or high blood pressure. Sympathectomy is often an effective way of dealing with this disease when irreversible changes in the essential organs such as the kidneys and heart have not as yet been produced. Sympathectomy at appropriate levels is also utilized in the treatment of certain vascular diseases of the extremities, particularly the vascular spasm of Raynaud's disease and Berger's disease.

**Congenital Anomalies.** The maldevelopment of the body, especially as it concerns the nervous system, may cause physical handicaps without impairment of mental faculties.

*Meningocele.* The commonest handicap is a meningocele. This is a development defect in the skull or vertebrae which may allow protrusion of the meninges. Surgical repair of this sac may be necessary to prevent rupture, meningitis, or progressive related change in the nervous system.

*Hydrocephalus.* Hydrocephalus, or water-on-brain, is an excess cerebrospinal fluid which may result from overproduction of fluid or interference with its absorption (communicating hydrocephalus), or from blockage of the fluid pathways within the brain (noncommunicating hydrocephalus). The latter can sometimes be helped by connecting the ventricle of the brain with the subarachnoid space by means of a tube. Unfortunately, the more common communicating hydrocephalus is rarely successfully treated.

*Vertebral Anomalies.* Congenital anomalies of the vertebral bones may exert pressure on the spinal cord. Laminectomy is necessary to decompress the constricted structures.

*Congenital Cysts.* Congenital cysts occur in the brain and spinal canal. They cause the same symptoms as tumors in the same location and are treated in the same way.

## ORTHOPEDIC SURGERY

In its present broad concept, orthopedic surgery is that specialty in surgery which treats fractures, injuries, and diseases of the spine, bones, muscles, tendons, and joints.

### SKELETAL DEFORMITIES

**Club Feet.** The Greeks treated club feet by stretching and wrapping the foot firmly with bandages impregnated with some white of egg solution in glycerine, which, when hardened, tended to serve the same purpose as the modern plaster of Paris cast. By this means, the foot was slowly stretched to a straight position and held there. Although the method was primitive, its basic principles are still used. In the eighteenth century, the marked deformed club foot, which had not been treated by these methods, was helped by the new development of lengthening the Achilles tendon, as originated by Lorenz in 1782. The modern method of correcting club feet is essentially that of the ancient Greeks, with the added advantage of using plaster of Paris as an adequate support. A club foot, noticed at birth, may have a plaster of Paris boot applied after stretching the foot to the corrected position. If the boot is reapplied at weekly intervals for a three-month period, until the child's foot grows into this overcorrected position, the club foot can be effectively corrected in most cases. There are always some few children who require subsequent lengthening of the Achilles tendon. These operations become less frequent the earlier the child is treated. When the modern orthopedic surgeon examines the untreated club foot of an adolescent child, he may find it necessary to perform a bony fusion operation, in addition to using the original plaster stretching and wedging that is a standard form of preliminary treatment. Children whose feet have been thus corrected grow up to have excellent use of their feet, and may indulge in sports and other normal activities. Usually, such children have some slight difference in the circumference of the calf muscles and in the length of the feet, the affected foot being slightly smaller in shoe size. The length of the affected leg, however, is normal.

**Metatarsus Varus.** The deformity of metatarsus varus is essentially a mild degree of contracture of a club foot, and is easily corrected by the application of a plaster boot alone. This deformity, too, is best handled during the first days of the infant's life. A foot of normal appearance should always result from treatment, since this common deformity lends itself easily to correction.

**Scoliosis.** Curvature of the spine is usually noticed in the growing child near the age of twelve. It is ten times more frequent in girls than in boys. Although many conditions may cause this type of deformity, such as an aftermath of infantile paralysis or Von Recklinghausen's disease, the major cause for this condition is unknown. As a general rule, the curve increases as the child grows, and stops when growth has been completed about the fifteenth year of life in the female. From that time onward, very little increase in the curve occurs, except for the normal amount of sagging that would take place with advancing age or with arthritis of the spine. The curve is usually not painful, and is not noticed until a considerable amount of curvature can be demonstrated by X ray. If it appears early in adolescence, the curve will increase markedly by the time the individual is fully grown. In the past, curvature of the spine was treated with braces, which attempted to push the spine into a more upright position and hold it there. This treatment failed to remove the underlying cause of the curve, and when the brace was removed, the curve sank back to its original position. The employment of special exercises, which stretch the contracted ligaments and muscles on the concave side of the curve, has been of benefit, but is rarely successful in making a completely straight normal spine. The modern treatment is to bend the spine into a corrected position by the use of a plaster body jacket, and then fuse the spine, after the technique of Russell Hibbs, so that the affected area of the spine will be welded or fused together into a compact mass and will not bend any more through that area. Although this operative method does not hit at the fundamental cause which produces the curve, it mechanically

holds the spine straight in spite of the forces which tend to produce the scoliosis. The usual technique is to apply a plaster body jacket, with the child bent over in the direction opposite to the curve in the spine. Either new plaster jackets are applied at weekly intervals to increase this bend to straighten the curve, or the plaster is cut in the middle and wedged firmly in the proper direction. When the curve has been straightened as far as possible, the back portion of the plaster jacket is cut out, and the operation is performed through the hole in this plaster. Following the operation, the child remains in bed in the original jacket, or in one similarly bent, for six months, when the spine fusion is perfectly solid. Then the child is allowed to walk without support, and the curve will not recur unless there is a failure of fusion of the operative bony mass. Although the spine thus fused is stiff and rigid in the area of the fusion, there is enough motion of the joints above and below the area of fusion to allow these children to appear perfectly normal. They may bend over and touch the floor, and may indulge in sports with freedom.

**Torticollis.** Torticollis, or wryneck, is a contracture of the sternomastoid muscle in the neck of the newborn infant which holds the head bent to one side, with the face turned toward the opposite shoulder. It is thought to be the result of an injury to the muscle at birth. It is corrected by dividing the muscle in the neck, usually just above the collar bone, making sure to divide the two strands of insertion of the muscle at that point. A plaster body jacket with a headpiece is then applied, holding the head tilted to the opposite side from the contracture and the face turned to the affected side, looking slightly upward toward the ceiling. The child remains in this plaster jacket until the divided muscle has healed in a lengthened position. Then the neck is massaged and stretched twice daily to maintain the full degree of correction. Babies affected with torticollis may be operated on as soon as their feeding has been well established. It is better to operate early than to wait until after the first year of life. If the contracture is not operated upon, the affected side of the face remains underdeveloped as compared to the normal side, so that the affected side of the face looks flatter, with the cheekbones sunk inward. The eye on this side of the face will be smaller and at a lower level than the normal one.

**Birth Palsies of the Shoulder.** Sometimes a baby, during birth, incurs such severe damage to the ligaments and nerves of the shoulder and neck that contractures develop in the shoulder, causing birth palsies. Such a deformity leaves the child with the arm held closely against the side in a contracted position, with the arm internally rotated, so that he is unable to move the hand far away from the abdomen, or stretch the arm overhead. If the nerve in the neck has not been completely torn, the use of massage with special exercise and the employment of a brace holding the arm in a corrected position may allow the damaged tissues to heal satisfactorily. Sometimes, however, the tearing of the nerve is so severe that it leaves the forearm and hand withered and useless. William II, emperor of Germany, had such an arm. The vast majority of birth palsies, however, are of mild degree, and improve with conservative treatment. Some patients develop contractures of the muscles in the shoulder joint, and consequently hold the arm against the side. Such cases can be relieved by an operation developed by James Warren Sever of Boston. The subscapularis muscle is divided at the shoulder joint, and the arm is then held by a brace in the position of "hands up" until the muscle has healed in its lengthened position.

**Congenital Dislocation of the Hip.** Congenital dislocation of the hip was recognized by the Greeks, and attempts to reduce such dislocations were made by successive generations of practitioners who resorted to direct longitudinal traction or pull. Congenital dislocation of the hip was generally considered to be incurable until 1888, when Agostino Paci described his method of reducing congenital dislocations by five complicated and precise movements. Eight years later, Adolph Lorenz, of Vienna, described another method of correction, which was essentially the same as that of Paci.

This method of "bloodless surgery" later gained widespread renown. The apparent success of Lorenz may have been due to the fact that he kept his patients longer in plaster than did Paci. This long immobilization in plaster allowed the socket of the hip to develop a greater depth, so that the hip would not later dislocate.

The modern concept of the treatment of this condition, however, is that only a small per cent can be successfully treated by manipulation alone. The modern trend is definitely toward adequate early surgery, involving complete socketing of the head within the hip joint, and removing the excess tissue present there that allows the head to slip out of place again. Some of these hip sockets, even then, remain shallow, and later may require a bone-graft operation to make an overhanging roof or shelf to stabilize the head in place. All of them require a second operation on the femur, or thighbone, to correct a torsion that tends to dislocate the head from the socket. In dislocated hips, as in other congenital deformities, the earlier the child is treated adequately, the better is the end result.

### DISEASES

**Tuberculosis.** Prior to the discovery of Russell Hibbs, in 1910, that fusion of a joint could successfully arrest tuberculosis, the treatment of bone tuberculosis had largely been confined to long periods of bed rest, and to excision of the diseased joint where possible. In the lower extremity this operation was not successful. The modern viewpoint is that the joint should be operated upon as soon as possible, and a fusion effected. In an upper extremity such as the elbow or the finger joint, excision is still successfully employed. In the case of the shoulder, spine, and hip joint, however, fusion is the operation preferred. Combined with this surgery, rest for a long period of time is still essential, but the disease can now be successfully arrested without fear that it will recur at some future date at that particular location.

**Infantile Paralysis.** Orthopedic measures in poliomyelitis were formerly directed toward stabilizing the paralyzed limbs by the use of braces. To this treatment has been added the stabilizing operation first discovered by Edward Albert in 1878. By fusion operation, the deformed joints can be straightened as well as stabilized, so that braces may be dispensed with in many cases. This type of treatment has widespread use, particularly in cases affecting the foot, where a subtalar fusion may give a firm platform on which to bear weight. Ankle fusions also have been eminently successful. A knee fusion gives a noticeable stiff-leg gait. A hip fusion gives an excellent gait, so that the patient may walk for miles without pain, frequently without any discernible limp. Curves in the spine following poliomyelitis, a frequent cause of scoliosis, may be straightened and fused. The transplantation of a tendon, to supply a strong tendon in place of a paralyzed one, is more successful in the upper extremity than in the weight-bearing lower extremity. This operation has, however, some value when it involves the knee joint or the foot.

### AMPUTATIONS

Amputation of legs and arms has been performed since prehistoric times. The necessary brutality of the guillotine type of amputation, with boiling oil cauterization, was not improved upon until Ambroise Paré (1510-1590) used a tourniquet to numb the limb, control hemorrhage, and pull back the muscles so that they later would fall over the bone and leave sufficient covering, or padding, for the stump of the bone. Paré actually ligated the bleeding vessels so that the amputation stump did not have to be dipped in boiling oil.

Later, more complicated types of amputation, with refinement in technique, were attempted. Napoleon's surgeon Dominique-Jean Larrey, in 1803, performed many amputations of the shoulder and hip joint, in addition to amputations of the more common type. Jacques Lisfranc, in 1815, described a method of amputation of a part of the foot. Nicholas Ivanovitch Pirogoff of St. Petersburg devised another type of amputation of the foot. James Symes devised an amputation at the level of the ankle joint. It remained for Robert Liston, an Englishman, to introduce, in 1890, the skin-flap amputation, which covered the raw end of the bone and muscle. This type of operation took longer to perform, but healed more quickly and gave an infinitely better result. In 1857, Rocco Gritti amputated at the knee joint and used the patella, or knee cap, turned under the end of a thighbone, or femur, and covered with a skin-flap to serve as the weight-bearing surface.

Originally, surgeons amputated as close to the mangled portion of the limb as was consistent with good healing and good blood supply to the skin edges. A site thus selected, however, did not always prove to be the optimum site of amputation from the standpoint of a limb-maker who had to make the artificial prosthesis. In the beginning of the twentieth century a convention in London, attended by both surgeons and limb-makers, resulted in the selection of optimal sites for amputation by mutual agreement between the two groups.

A remarkable advance was contributed by an Italian physician, Giuliano Vanghetti, who conceived the idea of utilizing the small contraction of the remaining muscles in the amputation stump, so that by means of a mechanism in the artificial limb these movements could be magnified and made to open and close artificial fingers with some degree of skill. This prosthesis is applicable only to the upper extremity. Better results are obtained if specialized training is given to the muscles before operation. This technique of amputation and appliance has a precision of control, and a directness of control, that is better than an artificial limb activated by shoulder-shrugs. The patient even learns a sense of feeling, size, and density. The disadvantages of the technique are a lack of power for the heavy work done by a hook on the end of the appliance. The apparatus is still crude, and parts break easily. The surgery for fine muscle control is still far ahead of modern engineering principles of limb-making. Most soldiers prefer the sturdier, simpler artificial hand that has a hook for heavy work and a simple pinching mechanism for grasping objects.

In modern wars, under anesthesia of course, the guillotine type of operation, together with the tourniquet and vessel ligation employed by Paré three hundred years ago, is still used. It is the safest means of amputation in busy evacuation hospitals where immediate surgery must be performed. As healing takes place, the skin edges are pulled down over the open bone end and held in place by means of adhesive tape traction on the skin, until only a small central scar remains. A plastic skin-flap operation may be performed at a later date at the base hospital if indicated. In civilian life, where speed and haste is not necessary, a skin-flap operation under anesthesia is usually employed. A novel development in amputations has been the freezing of the leg prior to operation. This method is occasionally used on some aged diabetics or other people having diseased blood vessels or infections. Cracked ice is simply packed all about the limb after a tourniquet has been applied high on the thigh. In an hour, anesthesia is complete, and the leg may be amputated without any other type of anesthesia. This type of amputation causes no shock to the patient, and the wound heals satisfactorily.

In choosing the site for amputation, the surgeon is naturally influenced by the findings of the limb-maker, who has learned from experience what sort of stump will fit the most efficient and comfortable artificial leg. In the lower leg, it is generally conceded that the "site of election" is about four to five inches below the knee joint. Many surgeons, however, believe that the Gritti-Stokes amputation through the knee joint gives a more efficient and less troublesome stump. The higher the amputation above the knee, the less efficient is the artificial limb in its function. It is necessary, in the case of these high amputation sites, to employ belt and shoulder straps to hold the artificial leg on the thigh. By means of these straps, however, certain motions of the artificial limb can be produced.

### TRAUMATIC CONDITIONS

Accidents and injuries produce many traumatic orthopedic conditions, such as fractures, or broken bones, and damaged muscles, ligaments, and joints.

**Tendon Surgery.** When muscles, tendons, and nerves have been cut or damaged by trauma, they are operated upon immediately and sewn back together. A severed tendon, when treated early, is usually sutured back to the parent tendon. If not treated until months or years after injury, a tendon graft may prove necessary, or the tendon end may be sewn to a neighboring tendon so as to give it more power. It is possible to transplant an unimportant tendon to fill in a gap left by the injury, especially in the hand. Severed nerves may be sutured together, and the vital portion of the nerve will grow further down the extremity at the rate of about three-quarters of an inch a week. Badly damaged muscles, however, especially if they have been deprived of their blood supply for more than twenty-four hours, never regenerate.

**Torn Knee Cartilages.** The medial meniscus, or cartilage, on the inner aspect of the knee joint is frequently damaged in athletics and in normal civilian life. This may cause the knee joint suddenly to "lock" or get caught in a bent position, so that the individual is unable to straighten his knee. Such an occurrence is usually followed by pain and swelling. When such a knee cartilage is removed, the knee is no longer placed in a plaster cast, but early motion is encouraged as soon as the anesthesia has disappeared. By this method, the patient is usually bearing weight within three weeks of the operation, and the residual function of the knee should be excellent. Many older people develop painful knees as a result of degeneration of this inner knee cartilage. In such cases, pain, if not accompanied by severe arthritis, usually can be relieved by excision of the degenerated cartilage.

**Painful Shoulder.** Trauma or accident may so wrench the shoulder that a portion of its capsule is torn. If this tear is extensive, repair of the torn capsule is necessary to

relieve the patient of pain. Occasionally the capsule undergoes degeneration as the result of frequent minor strains. A small portion will then develop a circular-shaped defect in the capsule where the ligamentous tissue has torn and frayed apart. Such a shoulder is improved markedly by an operation which cuts out the chronically inflamed area and repairs the capsule.

At times, too, the biceps tendon of the upper arm, which runs through the capsule into the joint, will slip out of place at the top margin of the bone. This tendon may have to be firmly anchored into the surrounding structures.

Frequent minor strain on the capsule of the shoulder may result in a deposit of calcium, which forms within the capsule in the process of healing and causes considerable inflammation and irritation, accompanied by severe pain at the point of the shoulder. If the capsule becomes acutely inflamed, it may rupture through into the bursa of the shoulder. Although a few of these calcium deposits can be made to absorb and disappear by conservative measures of massage and deep-heat treatments, many of them require surgical removal.

**Dislocation.** The most common dislocation is that of the shoulder joint. As a rule, the upper arm is dislocated forward and downward, tearing the attachment of the capsule to the socket of the shoulder blade. Such an injury is usually the result of an accident, but some sockets are so shallow, because of improper development, that dislocation may habitually recur. The dislocation is usually easy to reduce if the patient has been anesthetized. Although more difficult, it occasionally may be accomplished without anesthesia.

Habitual dislocation of the shoulder requires surgery. In this operation, the torn capsule and ligaments are reattached, the subscapularis muscle is tightened, and the arm is held bound to the side for six weeks before motion is allowed.

**Low Back Pain and Sciatica.** One of the most common ailments of mankind is a low back pain, called sciatica, in which the pain radiates down the leg. This malady is a frequent result of an injury to the back or of heavy lifting resulting in a tearing of ligaments, so that a portion of the cartilage disk that lies between the vertebrae is protruded backward, and presses on one of the nerves of the spine. The treatment lies usually in the direction of gentle manipulation intended to push the protruded cartilage back into its normal position in the spine. This manipulation, together with some support of the spine in the form of a corset, or brace, plus massage and physiotherapy, enables most people to return to work within a relatively short period of time. If the manipulation is successful, sometimes the sciatica will instantly cease. Special exercises are then used to re-educate the muscles which have been in marked spasm. Recurrences of the protrusion will recur, as a rule, with greater frequency, and they will require less injury to produce them. Surgery may be needed to prevent such recurrences. Patients on whom manipulation is unsuccessful, because too large a piece of material has extruded itself backward and is pressing on the nerve, likewise require surgery.

By surgery, the protruding piece of cartilage can be removed, eliminating its pressure on the nerve. Such excision will relieve the pain and spasm in the back. Additional pieces of cartilage may later be extruded backward through the same area unless the spine is fused by means of a bone operation which prevents motion at that area.

## FRACTURE

Fractures, or broken bones, have been the concern of healers since the dawn of man. Nature has provided a process within our bodies of healing these fractures which is essentially very simple. The blood that flows out around the broken ends clots within a few days and forms a jell which hardens and consolidates throughout the subsequent weeks, and finally turns into bone. This jell, or bony cement, takes many weeks to harden completely into firm bone. It is therefore evident that if the broken bones are held in proper position, this cementing process, when completed, will leave the bone in its proper alignment and shape. If the bones are not held still during the healing stage, angulation, shortening, or deformity may occur. Most fractures occur deep beneath the skin without causing sharp ends of the bone to protrude through the skin. Such fractures are known as "simple" fractures. "Compound fractures" are those which break through the skin, making possible an infection of the blood clot surrounding the bone. If the bone is shattered into many small pieces, the fracture is known as a "comminuted fracture." For thousands of years, the treatment of fractures has been based on the principle of pulling the angulated or overriding fractured bone into position, and holding it there until nature had completed its cementing process. This method of treatment is known as the conservative or nonoperative treatment of fractures.

Bones may also be held in proper alignment by traction during the many weeks during which healing takes place. Traction may be effected by the use of adhesive tape on the skin, or by metal wires pulled through the bone. Constant pull is maintained by the use of weights. This method is highly satisfactory, but requires constant attention and care. It allows a certain degree of motion of the limbs, but has some disadvantage in that it stretches the joints.

Conservative therapy is therefore the treatment of fractures by reduction, followed by either splinting or traction. It is still the treatment of choice for many fractures of the body, especially in children, for many infected or compound fractures, and for most common fractures, such as those of wrist, ankle, collarbone, and shoulder. Healing of the fracture by the bony consolidation of the bone clot occurs at a regular rate throughout the body, but is faster in children than in adults. Certain bones, however, need to be held in alignment by splints or by traction for longer intervals than others.

**Operative Treatment.** Operation on fractures has two main purposes. The first purpose is to reduce and align the fragments into proper position when they cannot be pulled down or manipulated into place by closed reduction. This step may be followed by splinting, or fixation in a plaster cast; the fracture is treated from that point onward very much as in the conservative type of treatment. The second purpose, which has developed since 1905, is not only to reduce and properly align the bone ends, but to hold them firmly in place by means of some metal internal appliance which is firmly screwed or fixed to the bone. When successfully accomplished, this internal fixation of fractures may eliminate the use of external plaster support, and will allow early motion of the joint and freedom of the use of the muscles. There is a danger of infecting the bone in this operative procedure.

The first report of an attempt at internal fixation credits Lapuyade and Sicre in 1775 with using wire to fix the bones in place. They were accused by the French surgeon Icart of causing the death of the patient in two days. In 1827, J. H. Roagers of New York successfully wired an ununited fracture of the humerus, or upper arm. In 1861, E. S. Cooper of San Francisco wired together a fractured patella, or knee cap, which successfully healed without infection. The real

birth of internal fixation of fractures, however, was not to come until 1905, when Sir Arbuthnot Lane of London published his book on the subject. Though various types of metal plates had been used prior to Lane's time, the latter's technique of thoroughly exposing the bone, reducing the fracture, and holding it in place by means of a metal plate screwed firmly to the bone is essentially the technique still employed. Developments since Lane's time have been chiefly minor modifications of his method, following the discovery of metals which are not irritating to tissues, so that the wound does not break down later and cause infection with draining sinuses. With the development of bone-graft surgery, still another method of internal fixation has become available. Inlay and onlay of bone grafts are used not only to stabilize the bone, in the same fashion as were the metal plates, but also to offer additional bone from which more callus and cement can be obtained for added strength.

Though the danger of infection is always real and ever present, the technique of internal fixation has been a great advance in orthopedic surgery. In fractures of the thigh and lower leg, it is possible to maintain full length and obtain union without the use of external support or traction. The patient's expensive stay in a hospital is accordingly reduced to a minimum. The residual function of the neighboring joints is infinitely better. The failure of union and the incidence of deformity are markedly reduced in competent hands and in selected fracture cases. Fractured hips in the aged, considered permanently crippling or terminal accidents in the past, are now treated by means of internal fixation involving the use of a specially shaped nail, with the result that approximately 80 per cent of such patients are able to walk successfully again. The high incidence of nonunion in two areas of the body, namely the lower third of the tibia, about four inches above the ankle, and the middle third of the forearm, has been greatly reduced. In fractures involving the knee joint, the elbow, and the shoulder joint, which formerly left much residual stiffness and loss of function of the joint, the use of open reduction and internal fixation holding the fragments in proper alignment has resulted in much more normal function. F. R. T.

## PLASTIC SURGERY

Plastic surgery deals with the reconstruction of tissue defects and the restoration of body areas that have been lost or deformed through injury, disease, or maldevelopment. It is necessarily associated with all other surgical specialties, but is identified chiefly with the transplantation of skin, bone, and cartilage in the correction of congenital abnormalities and scarred deformities, in cosmetic surgery about the face and breasts, and in the repair of burned surfaces and areas from which cancer has been removed. Its purposes are to establish normal contour and restore function.

**History.** Contrary to most opinion, plastic surgery is not of recent development but dates back to prehistoric times, when primitive man made crude attempts at repairing wounds inflicted by animals and savages. The Egyptians developed reparative surgery into an art and a science, and as early as 3400 B.C., in the First Egyptian Dynasty, healers were performing cosmetic operations on the face, feet, and arms. By 2500 B.C., they were utilizing sutures, adhesive tape, lint dressings, ointments, and antiseptics, and these practices spread throughout Asia Minor and were adopted by the Hebrews, Assyrians, Arabic, and Greek peoples. India, likewise, made early progress, and, by 600 B.C., doctors had employed forehead tissue flaps in the reconstruction of noses, had made free skin grafts from the gluteal region, and had used tissue glue, horsehair stitches, and local anesthetics. In the first century of the Christian Era, Celsus wrote about sliding grafts of tissue and skin; later, Galen described in detail the technique of reconstruction of the nose, ears, and mouth.

After a thousand years of stagnation during the Dark Ages, Gasparo Tagliacozzi in 1597 reviewed the technique of reconstruction of the nose. In the eighteenth century, the ancient Indian forehead flap was introduced into Europe by British surgeons who had seen it performed in India, and in the same century Pierre Desault encouraged the use of the pedunculated tissue flap. Free tissue transplantation, although practiced in ancient times, did not receive clinical application until 1869, when Reverdin proved its great value as a dressing for wounds. Ollier, Wolfe, and Krause furthered the utilization of larger sizes of free grafts, and in 1917 Gillies and Filatov devised the tubed graft.

World War I placed an immediate and vast responsibility upon the limited number of surgeons practicing reconstructive surgery. Unfortunately, progress in plastic surgery has been largely associated with the repair of war injuries and mutilations, and the plastic surgeon has been challenged throughout by the advancement in destructive weapons. Consequently, World War II created an even greater responsibility as new weapons and inflammable agents increased the types and severity of wounds. Thousands of soldiers requiring specialized plastic procedures were treated efficiently in hospitals designated as centers for these cases.

**Recent Developments.** In the past thirty years, covering both war periods, acceptable techniques have been standardized, superior instruments have been developed, and the principle of tissue grafting has been extended to all elements of the body. Actually, however, very little has been added to the theory of plastic surgery in the past 3,000 years. Perhaps the most significant recent advance has been in chemo- and biotherapy (sulpha, penicillin, streptomycin), asepsis and anesthesia. The control of infection has broadened the surgical application of reconstructive procedures and increased the opportunities for success, while new devices in anesthesia have permitted well-controlled surgical functions bringing little discomfort to the patient. Other improvements in surgical technique which were particularly applicable to plastic work were the control of hemorrhage, minimization of trauma to the wound, and the proper use of suturing materials.

**Classification of Grafts.** Tissue transplants may be classified as free grafts and pedicle grafts. The free grafts are severed completely from their original source of nourishment and moved to an independent area from which they will derive their sustenance. Mostly these grafts are composed of skin, but they may include such tissues as bone, cartilage, fat, fascia, muscle, tendon, nerve, gland, cornea, and blood vessels. These transplants are further classified as autogenous grafts, which consist of tissues separated and transplanted within the same individual, and heterogenous grafts, which consist of tissues acquired from another individual or an animal. This latter group comprises the homografts, which are transplanted from a body of the same species, such as man to man or dog to dog, and the zoografts, which are taken from different species, such as dog to man. Homogenous skin transplants are unsuccessful, but may be used as temporary dressing material in very large burned areas. Homogenous cartilage, bone, and corneal grafts are very often successful. Homogenous organ grafts, such as heart, kidneys, and lungs, and zoögenous transplants from animals to man have been unsuccessful.

### SKIN GRAFTS

**Types and Purposes.** The autogenous skin graft is used effectively in the replacement of lost skin in extensive wounds, as a dressing for third degree burns, and as a covering for raw surfaces in injuries and diseases. It promotes rapid, sound healing, reduces convalescence, and mitigates against infection and contraction. In preserving the normal function and shape of a section of the body, the accepted practice is to apply the graft as soon after the injury as practicable. If the wound is clean, this is done immediately.

Free skin grafts are identified as being very thin, or of split thickness, or of full thickness of the skin. They are acquired from a convenient donor site, such as the chest, abdomen, behind the ear, anterior thigh, and lower neck areas, by placing the skin under tension and slicing free the desired thickness with a sharp blade. The Padgett dermatome, introduced in 1938, permitted the operator to cut a graft of calculated thickness, width, and length by glueing the skin of the donor site to a drum, over which slides an adjustable cutting blade.

**Procedure in Grafts.** Practice requires that grafts be moved to the recipient areas without delay. If a short delay is unavoidable, the graft is kept in physiological saline solution or placed back on the donor site; if the delay is long, the graft is refrigerated. During the first forty-eight hours, the transplant receives its nourishment from the plasma in the recipient area. Capillaries gradually grow into the graft, and, by the fifth postoperative day, organic union begins with a layer of fibroblasts (white connective tissue cells) fixing the graft to its bed; then, over a period of weeks and months, nerves, fat, and fibrous tissue grow beneath and into the graft. The thicker grafts have shown less tendency to change color and contract after transplantation. They offer more protection and stability but have a greater incidence of failure to "take" than thinner grafts. Very thin grafts, on the other hand, may become highly pigmented and contract from 30 to 50 per cent of their original size. The split graft of medium thickness, obtained with the dermatome, has been found generally satisfactory.

The recipient area is prepared by washing with soap and water and antiseptics, by removal of excessive tissues which are unhealthy, and by control of bleeding. Recent application of human and bovine coagulants to stop bleeding and developments in chemo- and biotherapy have greatly increased the chances of "take" of the graft. The next step in accepted procedure is to immobilize the graft so that the blood supply may become established, and this is accomplished by sewing the graft into its new bed, and applying pressure dressings. In grafting about the face and in the mouth, it has been found necessary at times to drape the skin over a mold or stent to secure it in its new bed. A recently developed tissue glue, prepared from heparinized plasma, causes the graft to stick to the recipient area and eliminates the need for stitches and pressure dressings. Ordinarily, grafts are not inspected for one or two weeks after the operation.

### PEDICLE GRAFTS

**Types and Procedure.** Many of the plastic procedures on the body require the transplantation of large, thick areas of skin and subcutaneous tissues to add mass and shape and give a healthy, resistant covering to bare bone. This is accomplished by partially raising the desired amount of tissue from the body in such a way that one or both ends are left attached as a source of nourishment. The portion that remains attached to the body is called the pedicle, and it is through this stalk that the blood supply and life of the graft are maintained. The defective area is then brought to the graft, if possible, or the graft is gradually moved to the defective site by means of successive migrations. Grafts are migrated by having them transferred to the arm, and then moving the arm, with the graft growing on it, to the deficient area. These pedicle flaps usually are made in the shape of a tube, and may or may not be lined with skin.

**Various Uses.** These grafts are found to be most useful in orthopedic and facial reconstructive procedures. After transplantation, they maintain their original coloring, which is usually white, and often appear lumpy, but these defects can be overcome later when the grafts are thinned out and color matched to their new area by tattooing.

In the repair of deep scars and wounds of the hand or foot, practice has found it desirable to move the injured member to the donor site when possible. The hand may be placed against the abdominal wall to receive an immediate pedicle or tube flap, or it may be inserted beneath the skin of the abdominal wall and retained there for several weeks, or until the graft has attained a sufficient blood supply to warrant release. The scarred or ulcerated foot may be placed against the opposite calf for direct transfer of a pedicle graft, which is released after several weeks. Immobilization of the affected areas is accomplished with adhesive tape, plaster splints, and metal braces.

These thick pedicled tissue transplants have proved valuable in the repair of great loss of tissue anywhere in the body. Current practice uses other grafts as follows: lined flaps from the forehead (Indian), or arm flaps (Italian), for reconstruction of the nose; thin tubed and pedicle flaps for reconstruction of the orbit and ear; sliding cheek flaps, and lined pedicle grafts from the neck or chest, for building up new lips. The surgery usually is protracted and many operations may be required before the final stage of correction is reached.

### COSMETIC SURGERY

Cosmetic surgery has gained in popularity in the past twenty years. It deals primarily with the removal of scars and blemishes, repair of congenital defects, and improvement in contour. In attaining an inconspicuous scar, procedure requires that the wound edges should be vertical, precise, undermined, and accurately positioned with subcuticular fine silk, horsehair, or wire stitches. Wounds that are created with the intent of removing scars, keloids, tumors, blemishes, tattoos, and wrinkles are adapted to conform with Langer's lines, which are the natural lines of the skin. This minimizes the conspicuousness of the repaired wound.

**Harelip and Congenital Defects.** Congenital abnormalities are varied, multiple, and challenging to the surgeon. They may affect any part of the body, but plastic surgery is primarily concerned with harelips, cleft palates, deformed and webbed fingers and toes, arrested development of the bones of one side of the face, and abnormal ears. Harelips and cleft palates, which not only are disfiguring but interfere with swallowing and speech, are corrected in infancy and childhood usually by two or three operations. Webbed fingers and toes handicap the use of the hands and feet and are a source of embarrassment to young children. A free skin graft is often necessary to correct the web permanently. Surgeons hold that supernumerary fingers and toes should be removed early in life. Maldevelopment of the bones of the face requires a series of operations to arrange properly the distorted areas and build up the deficiencies by adding tissue to the cheek, nose, or jaw. Otoplasty has proved satisfactory for the correction of "lopped" or protruding ears.

**Nose Alterations.** Alteration of the nose involves the re-

moval of cartilage and bone in the large, hump type of deformity, and remodeling of the external shape. Flat or sunken noses are improved by the implantation of a carved piece of bone or cartilage. All incisions are inside the nasal cavity and no visible scars result.

**Face and Neck Lifting.** Face and neck lifting procedures for the purpose of eliminating wrinkles and pouches of baggy tissue have also been effective. Most of the incisions for removal of the tissue are beyond the scalp hair line and the cosmetic result is a firmer covering for the face and a more youthful appearance. The lifting of a paralyzed face with fascial strips taken from the thigh gives an animated expression to what would ordinarily be an expressionless mask. Contours of the face are created by the implantation of bone, cartilage, fascia, or fat. The bone is secured from the hip or shin, cartilage from the rib of the patient or from a cadaver, and fat and fascia from the host.

**Other Operations.** Correction of large and small mouth openings, double or thin lips, burns, scars, and tumors of the lips has resulted in restoration of function and shape. Surgeons sometimes find it necessary to graft skin or mucous membrane into the mouth to make a groove for the proper fitting of a dental plate or to release a scar.

**Psychological Effects.** Surgeons warn that the psychological import of gross deformities in children and adults should be carefully analyzed before any operation is contemplated. These individuals have often been abused and ridiculed about their abnormality and are unusually sensitive. On the other hand, improvement of the general shape and function of a defective organ enhances the patient's opportunities and creates self-confidence. J. J. C.

**SURICATE** [su′rɪket], a South African species, *Suricata tetradactyla,* belonging to the mongoose family, Herpestidae. Known also as the meerkat or slender-tailed meerkat, the suricate is a small animal of slender form, having a tail of about half the body length. The long, soft fur is gray in color and has black, transverse stripes across the hinder part of the back, the head being nearly white and the ears black. The suricate may be readily distinguished by its elongated nose and claws, and by the fact that its ears are differently colored from the rest of the head. The pencilled mongoose, *Cynictis,* is sometimes called the bushy tailed meerkat. G. M. C.

**SURIGAO STRAIT** [su′rigɑ′o], a narrow strait in the Philippine Archipelago separating Mindanao and Dinagat islands on the south and east from Panaon and Leyte islands on the north and west. It connects the Mindanao Sea with Leyte Gulf. From Oct. 22 to 27, 1944, the strait was the scene of a large-scale battle between units of the Japanese and American fleets, in which the Japanese suffered disastrous losses. Their surviving vessels escaped to the west. R. G. B.

**SURINAM** [su′rɪnam], often called Dutch or Netherlands Guiana, an overseas territory of the Netherlands, on the north coast of South America. It is bounded on the north by the Atlantic Ocean, on the east by French Guiana, on the south by Brazil, and on the west by British Guiana (Demerara). It has an area of 55,129 sq. mi. The eastern and western boundaries are formed by the Maroni and Courantyne rivers respectively, and on the south are dense forests, savannas, and the Tumucumaque Mountains, which separate it from Brazil. The Wilhelmina Mountains, 3,000 to 4,000 ft. high, in the interior are the source of a number of rivers, the most important of which are the Suriname, Saramacca, Coppename, and Nickerie, all flowing northward to the Atlantic and forming the principal avenues of transportation. The climate is hot and humid, and there are two wet and two dry seasons. Paramaribo at the mouth of the Suriname is the capital of the colony and the largest city, with a population in 1947 of 75,233. Nieuw Nickerie, with 3,472 inhabitants, is the only other settlement of any importance. The population of Surinam, estimated at 207,684 in 1947, excluding bush Negroes and forest Indians, consists mainly of British East Indians, Javanese, and Negroes working in the mines, towns, and on subsistence farms. Agriculture, timber, and gold and bauxite mining are the major activities, and exports include bauxite, most of which goes to the United States, gold, sugar, rum, coffee, rice, fruits, balata, and timber.

**History and Government.** Surinam was first settled by the English in the early part of the seventeenth century, but in the Anglo-Dutch War of 1665-1667 it was seized by the Dutch, who obtained *de jure* possession of the territory at the Peace of Breda (1667) in exchange for the Dutch colony of New Amsterdam (New York). Surinam was again held by the English from 1799 to 1802 and from 1804 to 1816.

Divided into seven districts, Surinam was administered by a governor and council appointed by the crown until 1950, when it achieved a measure of autonomy through a new constitution and was given control of its domestic affairs. The Netherlands retained control of foreign affairs and defense. *See also* Guianas, The. C. W. D.

**SURINAM CHERRY,** an evergreen shrub or tree, *Eugenia uniflora,* growing as high as 25 ft. It is a member of the myrtle family. The surinam cherry is a native of Brazil, and is hardy in southern Florida and Southern California. The fruit, ½ to 1 in. in diameter, deep crimson when ripe, is 8-ribbed and edible. Preserves are made from it. L. de F.

**SURINAM TOAD,** an aquatic toad, genus *Pipa,* which inhabits the Guianas, Venezuela, and Brazil, and is famous for its peculiar breeding habits. The male directs the protruded oviduct of the female over her back and presses the extruded eggs into her softened skin. The female carries the eggs in these tiny pockets until the young complete metamorphosis. A lid covers each pocket and protects the young until they become tiny toads. The adults have broad flattened heads, huge webbed hind feet, and rather slender front feet which have long fingers ending in star-like tubercles. They grow to a little over 6 in. long. The roughened skins of these toads often harbor poison glands. A. Sv.

**SURNAMES.** *See* Personal Names.

**SURREALISM,** a movement in twentieth-century culture described by André Breton, its founder, as "pure psychic automatism by which it is proposed to express orally, in writing, or by any other means, the real functioning of thought . . . dictation of thought, in the absence of any control exercised by reason, beyond any esthetic or moral preoccupations." It was formally organized in 1924 as a reaction against the sterility of Dada; and it combined Cubism's systematic disintegration of conventional concepts with elements of the new theories of Einstein and Freud. Primarily a metaphysical attitude, it believed in the existence of an ideal higher reality, the *Surréel,* experienced by us only in childhood and dreams, when we knew the true essence and position both of ourselves and of our universe. This state of universal harmony could be regained by breaking the bonds of conventional thought to release the subconscious imagination; then the *Surréel* would be able to de-

velop and, after causing an alteration in the general mode of thought, completely take over man's destiny and transform the unsatisfactory conditions of human existence. However, part of the movement split away in the late 1920's, believing that a more direct revolution would in the wake of social upheaval leave a clean slate on which to work the necessary transformation. Although the movement was mainly literary at its beginning, its painters took the ascendance after 1930, and it was chiefly through them that its ideas and influence spread. Connected with Surrealism at one time or another have been the authors André Breton, Philippe Soupault, Paul Eluard, Louis Aragon, Tristan Tzara, and Robert Delnos, and the painters Francis Picabia, Yves Tanguy, Max Ernst, Salvador Dali, Joan Mirô, and André Masson.

**SURREY, EARL OF (HENRY HOWARD)** (c.1517-1547), English poet, son and heir of Thomas, third duke of Norfolk, was born about 1517. As a boy, he made translations from Latin, Italian, and Spanish. Henry VIII chose him as companion for his natural son Henry at Windsor and at the French court, and considered him as a husband for Princess Mary; but Surrey, when fifteen, married Frances de Vere. He served as earl marshal at Anne Boleyn's trial in 1536. Surrey was confined at Windsor in 1537 for striking a courtier and was twice imprisoned—in 1542 for sending a challenge, and in 1543 for shooting stonebows at London citizens and houses. He campaigned in Scotland in 1542 and in France during the next four years. Charles V praised him, and Henry VIII appointed him lieutenant general commanding the English forces. The Earl of Hertford, however, superseded him early in 1546 and in December had him sent to the Tower. Convicted of treason on a trumped-up charge of assuming royal arms, Surrey was beheaded on Jan. 19, 1547.

Surrey's first published poem was an epitaph (1542) on Sir Thomas Wyatt. Following Wyatt, Surrey naturalized the sonnet in English, establishing the new English form of three quatrains and a couplet. His sonnets, published in *Tottel's Miscellany* (1557), inspired Sir Philip Sidney and other Elizabethans. Surrey introduced blank verse into English by his translations from Vergil's *Æneid*.

M. E.

**SURREY,** a county in southeastern England, with an area of 722 sq. mi., bounded by the counties of Middlesex and London on the north, Kent on the east, Sussex on the south, and Hampshire and Berkshire on the west. The chalk hills of the North Downs intersect the county in an east-west direction. From them the surface slopes gently to the Thames River on the north and descends to a plain called the Weald in the southern part of the county. Most of Surrey is drained by the Thames and its tributaries, the Wey, the Mole, and the Wandle. Surrey is one of the five Home Counties of Kent, Surrey, Middlesex, Essex, and Hertford, which surround London. The southern part of London and its suburbs are in northern Surrey. Box Hill, 596 ft., and Leith Hill, 965 ft., are the highest points in southern England. Guildford and Kingston are the county towns, with the assizes at Guildford and the county council at Kingston. The records of Guildford go back to King Alfred's time, in the ninth century. Fuller's earth is worked at Nutfield and Reigate. There are manufactures of drugs, tobacco, woolen goods, and calicoes. The ports on the Thames share the trade of the port of London. Dorking, an old market town, has given its name to a breed of fowls. At Mickleham is a church famous for two weddings: Fanny Burney's in 1793, and George Meredith's in 1864. Epsom salts are named for the mineral springs at Epsom, discovered in 1618. The county returns ten members to Parliament. Pop. 1954, 1,616,000.

S. Van V.

**SURTEES, ROBERT** [sɜ′rtiz] (1779-1834), English antiquary and topographical historian, was born at Durham on April 1, 1779. Educated at Christ Church, Oxford, and at the Middle Temple, he early developed an interest in antiquarian research, the fruits of which are to be found in his great work, the *History and Antiquities of the County of Durham* (4 vols., 1816-1840). He also composed local ballads that were frequently mistaken for traditional poetry. Surtees died at Mainsforth on Feb. 11, 1834. In the same year the Surtees Society was founded to publish documents relating to the history and antiquities of northern England.

E. R. A.

**SURTEES, ROBERT SMITH** (1803-1864), English novelist and writer of sporting stories, was born in Durham in 1803. He was educated for the law and turned this to account in some of his writings. In 1832 he became a founder of the *New Sporting Magazine* and was the editor for five years. His contributions to this magazine were later published (1838) as *Jorrock's Jaunts and Jollities,* which is said to have inspired Dickens' *Pickwick Papers.* Other books by Surtees include *Hillingdon Hall* (1845) and *Mr. Facey Romford's Hounds* (1864). He died on Mar. 16, 1864.

**SURVEYING,** the technique of locating points on or near the earth's surface. When the areas involved are limited in extent, the earth is considered to be a plane and the work is called plane surveying. A geodetic survey covers so large an area that the true shape and size of the earth must be taken into consideration.

The Egyptians are credited with being the first to carry on surveying operations. Annual flooding of farm lands by the Nile and consequent destruction of monuments marking the corners of individual pieces of property necessitated some system for reproducing obliterated lines and corners after the floods. Hence, much of the early mathematics and surveying concerned property boundaries. The first recorded measurements to determine the size of the earth were also made in Egypt, where the Greek geometer and astronomer Eratosthenes measured a meridian arc in 230 B.C.

SURVEYORS' THEODOLITE

COURTESY OF U.S. COAST AND GEODETIC SURVEY

**Work of the Surveyor.** The earliest tasks of modern surveyors also were concerned with the size and shape of parcels of land, to calculate the areas inclosed and to gather sufficient data to prepare descriptions when the lands were

conveyed by deed from one owner to another. As was the case in Egypt, many of these corners often disappeared and the land lines became obliterated. It then became the task of the surveyor to retrace these lines and to replace the corners in their former positions. The magnetic compass, known to the Chinese as early as 2000 B.C., was used to determine directions when much of the public domain in the United States was being surveyed for disposal to the early pioneers. Directions obtained by the magnetic compass may be considerably in error. More exact directions result from observations on the sun, or on a star.

The purpose of many surveys is the preparation of a map showing roads, streams, buildings, and other features in their correct relative positions, both horizontally and vertically. By studying such a map, new highways, railroads, hydroelectric plants, irrigation schemes, and other engineering projects can be planned. After these structures have been designed, the surveyor is called upon to give lines and grades so that they may become realities. The competent surveyor must have a thorough knowledge of mathematics, physics, and astronomy, since many principles of surveying are direct applications of these sciences. If engaged in land surveying, he must be familiar with the legal principles involved. He should be a neat draftsman, capable of turning out a legible map. He must be aware of the sources of error in his field operations, and must know how to detect and eliminate them from his final results.

## SURVEYING INSTRUMENTS

**Tapes.** Steel tapes, varying in length from 3 to 1,000 ft., are used for the direct measurement of horizontal distances. A 100-ft. tape, graduated decimally into feet, tenths of a foot, and hundredths of a foot, is the most convenient for most field operations. In the construction field, where architects' and engineers' plans for a structure are usually dimensioned in feet and inches, a tape similarly graduated is desirable. Tapes used by the United States General Land Office surveyors are multiples of the 66-ft. Gunter's chain. A tape made of a nickel-steel alloy, known as Invar, which has a very low coefficient of expansion, is used for extremely precise work. Invar tapes are frequently 50 meters long, since most geodetic work is based on metric units.

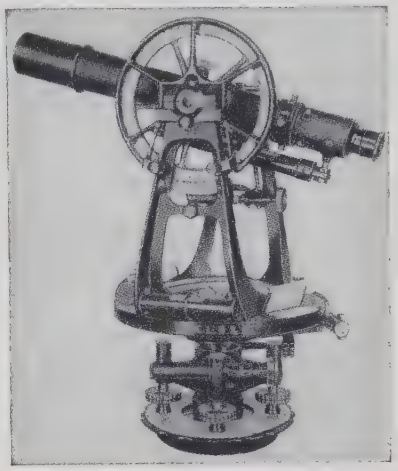
**Transits and Theodolites.** An engineer's transit is indispensable for field operations. It is provided with either an erecting or inverting telescope which can be moved both horizontally and vertically. Graduated horizontal and vertical circles permit the measurement of angles in these planes. European engineers call the transit instruments theodolites. American usage reserves the term theodolite for a more precise instrument.

The directions of the telescope on an ordinary transit can be read by means of attached scales called verniers to 30 seconds (″) or to 1 minute (′) of arc. Some theodolites can be read to 10″; others, equipped with micrometer microscopes or an arrangement of optical prisms, permit readings of tenths of seconds to be made. A bubble tube attached to the telescope enables the instrumentman to bring the telescope to a horizontal position when the transit is being used as a level.

**Engineer's Levels.** The engineer's level differs from a transit in that the telescope can be rotated in only a horizontal plane, and no angles can be measured with it. It has only one bubble tube. The telescope is brought into a horizontal plane by leveling over one pair of leveling screws, then turning it 90° and leveling with the other pair.

There are two common types of levels, the wye and the dumpy. The telescope of the wye level rests in Y-shaped supports and is held in place by hinged clips. These clips can be opened and the telescope turned end for end in the wyes when the adjustment of the instrument is being tested. The telescope of the dumpy level is rigidly attached and cannot be removed from its supports. It has fewer moving parts and requires adjustment less frequently than the wye level.

A level of the dumpy type is used for work of the highest precision. It has three leveling screws instead of the customary four. Approximate leveling is accomplished by observing the position of a small circular spirit level. The final centering of a very sensitive telescope bubble is achieved by turning a tilting screw, located near the eyepiece end of the telescope. A mirror, or an arrangement of optical prisms, enables the levelman to note the position of the bubble at the instant observations are being made. Three horizontal cross hairs permit more exact observations and the determination of approximate horizontal distances. The telescope has a much higher magnifying power than is found on less precise levels.



*SURVEYORS' TRANSIT*

C. L. BERGER & SONS

**Plane Table.** The plane-table outfit is used for topographic mapping. It consists of a drawing board supported by a tripod. The board can be leveled and rotated into any desired position without disturbing the tripod legs. Observations are made with the alidade, which consists of a metal ruler or straightedge supporting a telescope.

The telescope moves horizontally as the ruler is turned; it has a vertical movement in a plane that contains the edge of the straightedge or is parallel to this edge. It is equipped with a level tube and has a vertical circle for the measurement of vertical angles. Three horizontal cross hairs, called stadia hairs, allow the topographer to measure horizontal and vertical distances.

**Other Equipment.** In addition to the instruments previously mentioned, certain other small equipment is needed. Plumb bobs and a hand level are required for taping distances over rough ground. A variation of the hand level, the clinometer, is utilized to determine the slope of the ground surface when moderate precision is sufficient. A spring balance is used to maintain a uniform tension. Temporary locations of the tape-ends are marked on the ground by large spikes, or by more elaborate measuring pins made of heavy wire, often painted or enameled. Rods of metal or wood, pointed at one end and painted in distinctive colors, are used for transit work. These rods are called sight rods, line rods, or pickets. The common type of leveling rod is wooden, graduated in hundredths of feet. For stadia work,

longer distances are encountered, and a rod with coarser graduations is necessary.

## LEVELING

If the earth's surface were entirely covered with water and if there were no tides or waves, the resulting surface would be a level one. The elevation of a point is its vertical distance above or below the level surface known as mean sea level, which has been determined by gauge readings extending over many years. Some vertical distances can be measured directly with a tape. Others are determined trigonometrically by measuring a vertical angle, and a horizontal or a slope distance. For approximate values, an aneroid barometer can be used. Results obtained with a level and a rod are the more precise.

Two government agencies, the U.S. Coast and Geodetic Survey and the U.S. Geological Survey, have run many lines of levels over all parts of the United States and have set monuments at frequent intervals. These monuments, called bench marks, consist of bronze disks, usually set in the tops of concrete posts. Their elevations above mean sea level have been very accurately determined, and they serve as starting points for the surveys of local engineers and surveyors.

**Differential Leveling.** When the primary purpose of the leveling is to determine the elevation of a distant bench mark (B.M.), the work is called differential leveling. The procedure is indicated in Fig. 1, where the elevation of B.M. *A* is known and that of B.M. *B* is required. The level is set up where a rod held on B.M. *A* can be viewed through the leveled telescope. This rod reading, $+s$, is the vertical distance from the bench mark to the horizontal plane of the telescope. The elevation of the telescope, called the height of instrument (H.I.) can be obtained by adding the rod reading to the known elevation of the bench mark. The rod is then moved toward the distant bench mark and a rod reading, $-s$, taken on some stable point. The point where the rod is held is called a turning point (T.P.) and permits the levelman to move his instrument from one position to another. If the $-s$ rod reading is subtracted from the H.I., the elevation of the T.P. is obtained.

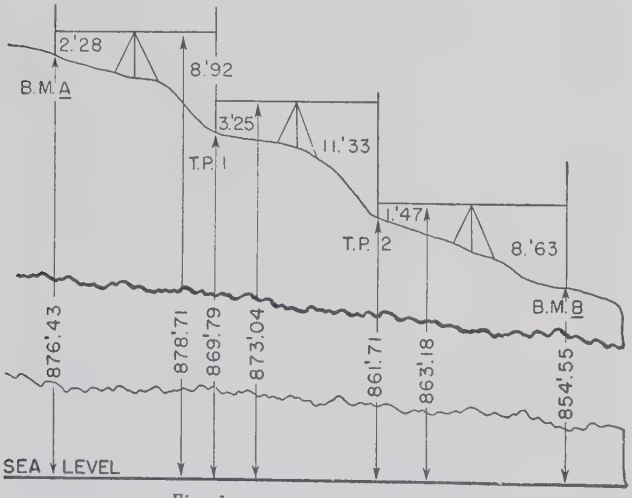

*Fig. 1—DIFFERENTIAL LEVELING*

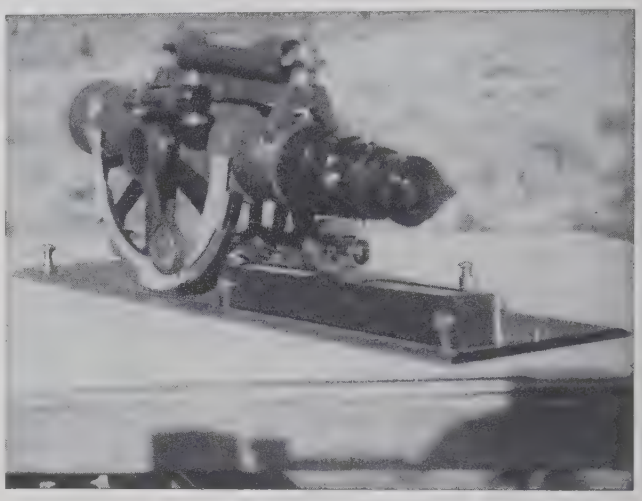
These two operations, a reading on a point of known elevation and another on a point of unknown elevation, are the fundamental steps in leveling. After the level is moved, a sight is taken on the turning point to the rear and on a new forward one. This process is repeated until a rod reading can be taken on the distant bench mark. Levels should be run over the line in the reverse direction to check the accuracy of the rod readings.

**Profile Levels.** The object of profile leveling is to determine the elevations of the ground surface along some definite line. These elevations are required whenever a railroad, highway, sidewalk, canal, sewer, or transmission line is to be designed. The route followed may be a single straight line, a broken line, or a series of straight lines connected by curves. From elevations determined in the field, a graphical representation of the intersection of a vertical surface with the surface of the earth can be prepared on paper especially ruled for the purpose. A vertical scale much larger than the horizontal one is used to accentuate the differences in elevation.



COURTESY OF STANDARD OIL CO. (N.J.)

*SURVEYORS' ALIDADE AND PLANE TABLE*

The route followed usually is marked on the ground by stakes set at uniform distances apart, say 100, 50, or 25 ft., depending on the regularity of the ground surface and the accuracy required. The beginning point of the survey is designated as Station 0. Points at multiples of 100 ft. from this point are termed full stations. Thus, points at distances of 100, 200, 500, and 1,000 ft. from the starting point are Stations 1, 2, 5, and 10, respectively. Intermediate points are designated as pluses. A point 1,428.75 from the beginning point is Station 14 + 28.75.

The difference in field work between profile and differential leveling is in the number of $-s$, or foresight readings, taken from each setting of the level. In differential leveling, only one such reading is taken. In profile leveling, readings are taken on as many points as are visible from a position of the level, and which are not too far distant from the instrument. The elevations of these points are calculated by subtracting the $-s$ readings from the proper H.I. When no more points along the profile can be seen, a $-s$ reading is taken on a turning point and the level is moved forward along the line. Bench marks are established at frequent intervals, if they have not been set beforehand, and check levels are run between them to detect and eliminate errors.

**Grade Elevations.** A grade line is drawn on the plotted profile to indicate how the original surface shall be altered during the proposed construction. The rise or fall of the grade line, in feet per 100 ft. of horizontal distance, is called the per cent of grade. The selected grade line should have suitable rates of grade and, in the case of a highway or rail-

road, the volumes to be moved should not be prohibitive. The excavated material is used in embankments when the distance to be hauled is not too great.

The edges of deep cuts and fills are found by trial on the ground. When the grading is nearly complete or before forms are set for a concrete pavement, or before the rails and ballast are placed on a railroad grade, stakes are set at the grade elevations. The grade elevation at a survey station is calculated from the grade line. The H.I. of the level is obtained by taking a $+ s$ reading on a bench mark or other point of known elevation, and the stake is driven until the $- s$ reading on it is equal to the difference between the H.I. and the grade elevation. On building-construction projects, required elevations are set in exactly this same manner, that is, by subtracting the required elevation from a known elevation of the level.

## LAND SURVEYING

**Purposes.** The purposes of land surveying are to subdivide large parcels of land into smaller ones, to determine the size and shape of existing parcels so that deed descriptions can be written to permit its legal transfer, and to attempt to relocate the lines of earlier surveys which may have become obliterated.

In the older sections of the United States, the boundaries of many farms are natural ones, such as watercourses, tops of ridges, or bottoms of valleys. The directions of these boundaries were determined with a magnetic compass in the original surveys, and the lengths were measured with a Gunter's 66-ft. chain. The restoration of the original corners is often a difficult assignment, calling for considerable skill and infinite patience in the search for possible remains of the original corners.

**United States Public Land Surveys.** The United States rectangular system of survey of public lands was inaugurated for the disposal of the public domain. It provided for marking the lines on the ground, and furnished a simple method of property description. The original ordinance, passed on May 20, 1785, established townships 6 mi. square, containing 36 sections, 1 mi. square each. It was soon found that the requirement of true north-south and east-west boundary lines was a geographical impossibility. Improvements in surveying methods have resulted in numerous changes in the original survey instructions.

The first step in making the survey was to establish an initial point near the center of the area being subdivided. A principal meridian was then run north and south through the initial point to the boundaries of the tract. Monuments were set at half-mile intervals along this line to mark the quarter-section and section corners. The second line was the base line, which is a parallel of latitude, extending east and west from the initial point to the limits of the survey. It is a small arc which, when marked on the ground, becomes the arc of a circle with chords one-half mile in length. Additional parallels, called standard parallels, were run at multiples of 24 mi. north and south of the base line. The area was divided next into quadrilaterals approximately 24 mi. on a side by running guide meridians at multiples of 24 mi. east and west of the principal meridian. These guide meridians extend 24 mi., or from one parallel to the next, to prevent the effects of the convergence of meridians from becoming excessive. The township boundaries were formed by running meridians north for 6 mi., and then connecting that township corner with the one slightly less than 6 mi. west of it. The discrepancy in distance due to convergence was thrown into the last half mile.

In dividing the township into sections, the north and south lines were run parallel with the east side of the township, rather than as true meridians. All errors in chaining were thrown into the most northerly half miles of the township, and the discrepancies due to convergence were thrown into the most westerly half miles. The full sections should contain 640 acres, whereas any section in the west tier may be expected to contain less than that acreage.

**Legal Descriptions.** One of the aims of the United States system of land subdivision was to provide a simple method of property description. The "N.W. ¼, S.E. ¼, Sec. 22, T. 3 S., R. 7 W., Third Principal Meridian," is an example of such a description. This 40-acre parcel is located in the township which is the third one south of the base line and the seventh west of the principal meridian. Since the sections within a township are always numbered in the same way, the position of the section within the township is definite.

The original survey monuments were set at half-mile intervals along the section lines. The division of section 22 into quarter-quarter sections is the task of the local surveyor. Quarter sections are formed by connecting the quarter-section corners on opposite sides of the section by straight lines. The intersection of these two lines is the legal center of the section. The southeast quarter of this section is divided into quarter-quarters by finding the mid-points of the boundaries of the quarter section and running lines to connect the opposite mid-points. The northwest quarter of this southeast quarter is the piece which has been described. The rules for the subdivision of sections along the north and east sides of the township are somewhat different.

**Metes and Bounds.** Where the rectangular system of subdivision has not been used, parcels of land are described by metes and bounds. In this type of description, the bearing and length of each side are given, together with the starting point and a statement of the objects used as corner monuments. A plat or map, drawn to scale, frequently accompanies the description.

**State Coordinate Systems.** The United States Coast and Geodetic Survey has calculated the plane coordinates, on a state-wide basis, of many monuments set by that organization and by some other survey agencies. These plane coordinates are the distances, in feet, by which the point is north and east of a definite starting point or origin. The length and direction of any line can be computed if the coordinates of the ends of the line are known. If a property survey can be connected to one of these monuments by measuring the angles and lengths of the lines joining the monument with one or more of the property corners, the coordinates of all the corners of the property can then be calculated.

## CALCULATION OF AREAS

**Field Measurements.** The most frequently used method for determining the area of a parcel of land is known as traversing. It consists of measuring the lengths of the sides and either the interior angle at each corner, or the angles which the sides make with a meridian. These latter angles are called azimuths, and are measured clockwise from the meridian. Most surveyors measure them clockwise from the north point; geodesists and astronomers reckon them from the south.

If the survey has been connected with monuments of the U.S. Coast and Geodetic Survey, the azimuth of a starting line can be secured from the information provided by that agency. The transit is manipulated so that the azimuths are obtained directly from the plat readings, or they may be

calculated from the one known azimuth and measured interior angles. When no known azimuth is available, one can be determined astronomically. Where the sole purpose of the survey is to ascertain an area, azimuths can be measured with respect to an assumed meridian.

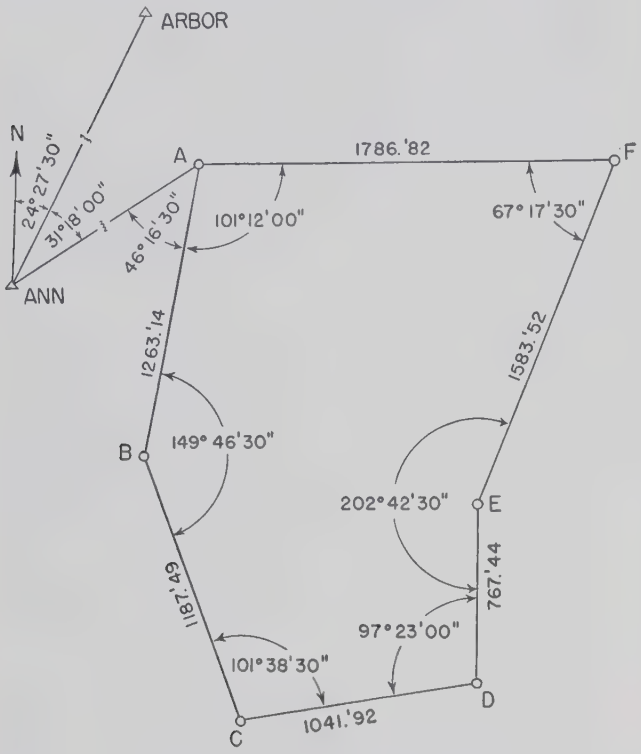


*Fig. 2—CALCULATION OF AREAS BY TRAVERSING*

The accuracy of the azimuths is tested by occupying the first transit point a second time after going entirely around the figure, and comparing the final azimuth of the starting side with its original value. The difference between the two is a measure of uncompensated errors. When interior angles are measured, their sum should total $(N - 2) \times 180°$, where $N$ is the number of angles in the closed figure.

**Office Computations.** The computation of the area of traverse can best be explained by reference to Fig. 2. In this survey one corner, $A$, has been connected with a triangulation system and the interior angles and lengths of the sides have been measured. From these angles the azimuths of the sides have been calculated. If the length of a side is multiplied by the sine of its azimuth, the east and west projection of the side, called the departure, is obtained. Multiplying by the cosine gives the north and south projection, called the latitude of the side.

Since the figure is a closed one, it is obvious that the sum of the east distances should equal the sum of the west ones and the sums of the north and south latitudes should also agree. Although the above sums are not identical, they are well within reasonable limits of error. The errors are distributed in proportion to the lengths of the sides, and the corrected values are used in computing the coordinates. These are the distances by which the corners of the parcel are east or west and north or south of corner $A$. The plus distances are east and north while the negative ones are west and south.

**Area from Coordinates.** The area can be calculated by the coordinate formula, in which the double area is obtained by multiplying each $X$ coordinate by the difference between the $Y$ coordinates of the two adjacent stations, always taken in the same order.

AREAS FROM COORDINATES FOR FIG. 2

| | | | 3,363,270 sq. ft. | |
| | | | =77.21 acres | |

**Area by Double Meridian Distances.** The double meridian distance of a side of a traverse is the sum of the two parallel bases of the trapezoid formed by drawing lines from the ends of the line perpendicular to the meridian through the most westerly station. If the double meridian distances are multiplied by the latitudes of the corresponding

*Corrected value

sides, the algebraic sum of the areas is the double area of the traverse. Areas formed by north latitudes are considered positive; those formed by south latitudes are negative.

## ROUTE SURVEYS

The center line of a railroad, highway, or canal consists of a series of straight lines connected by curves. The grade line on the profile also is made up of straight lines and curves. The curves used for the horizontal alignment are arcs of circles and spirals; the curve connecting the straight lines on a grade line is a parabolic arc. Horizontal curves on high-speed railroads and highways are made up of three

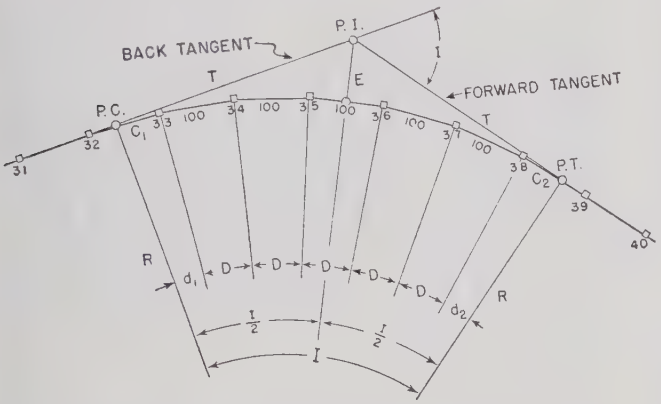

*Fig. 3—SURVEYING A CIRCULAR CURVE*

sections: first, a curve of varying radius; next, the central portion, which is circular; and, finally, a second variable-radius curve connecting the far end of the circle with the new straight line.

The necessity for the spiral or easement curve is to permit a gradual raising of the outer rail with respect to the inner one. For a velocity of $v$ ft. per second, the outer rail, which is $g$ ft. from the inner one, should be elevated $gv^2/32.2R$, where $R$ is the radius of the curve, also in feet.

**Circular Curves.** Although theoretically two intersecting straight lines can be connected by an infinite number of circles, actually on a highway or railroad the number will be limited by conditions existing on the ground. The circle selected may be described by its radius, or by its degree of curve. This is the angle at the center of the circle, subtended by a chord (or by an arc) of 100 ft. The chord definition is the older one, used in railroad practice and by many highway engineers. Some of the latter prefer the arc definition.

The relations existing between the various parts of the curve shown in Fig. 3 are expressed by the following formulas:

$$R = \frac{50}{\sin\frac{D}{2}} \qquad T = R\tan\frac{I}{2}$$

$$E = T\tan\frac{I}{4} = R\,\mathrm{exsec}\frac{I}{2} \qquad \sin\frac{d_1}{2} = \frac{c_1}{2R}$$

$$c_2 = 2R\sin\frac{d_2}{2} \qquad L\ (\text{approx.}) = \frac{I}{D}\times 100$$

The line is marked on the ground by the station method, described in connection with profile leveling. The first point on the curve beyond the *P.C.* is at a distance $c_1$, usually less than 100 ft. The chord subtends an angle $d_1$. The short chord at the end of the curve, $c_2$, subtends an angle $d_2$. The length of the curve, $L$, is the sum of $c_1$, $c_2$, and the length of the 100-ft. chords making up the rest of the curve.

Points on the curve are most easily located by the method of deflection angles. The transit is set up at the P.C., a pointing is made on the P.I., an angle $d_1/2$ is turned, and the first station is set at a distance of $c_1$ from the P.C. The next point is set at a distance of 100 ft. from this station, and on a line making an angle $(d_1 + D)/2$ with the back tangent. Other points are set in a similar manner, measuring horizontal distances of 100 ft. from the preceding ones, and increasing the total deflection angle by $D/2$ for each new point. The accuracy of the work is checked by comparing the measured and calculated values of $c_2$, and by noting how exactly the last line of sight with a deflection angle of $I/2$ strikes the point previously set to mark the P.T.

Although the computations for the staking out of a circular curve can be made by an application of the formulas listed above, the task is greatly simplified by the use of tables prepared for the purpose and found in most railroad and highway handbooks. These handbooks also contain tables useful in calculating spiral easement curves.

**Spiral Easement Curves.** The equation of the curve used as a spiral easement curve is of the form:

$$x = \frac{l^3}{6R_c l_c},$$

where $x$ is the tangent offset to a point on the curve, at a distance $l$ from the beginning point of the spiral. $R_c$ is the radius of the circle beyond the spiral, and $l_c$ is the length of the spiral.

This easement curve can be staked on the ground by the deflection-angle method. Because the radius varies from infinity to $R_c$, the curve subtends a central angle half as large as would a circular curve of the same length. The deflection angles are one-third of the central angles, and they vary as the squares of the distances from the beginning point of the spiral. From these relations the deflection angles can be computed, or they can be taken from the tables in the railroad and highway-engineering handbooks. One set of such tables is based on the assumption that ten points are to be located on the curve. The handbooks also contain diagrams indicating the proper length of curve required for smooth riding at a given speed around a curve of known radius.

The length selected and the amount of superelevation must be a compromise, since railroads must care for both passenger and freight trains. Highways must provide for both passenger and truck traffic traveling under dry, wet, and icy pavement conditions. Consequently, the amount of superelevation is somewhat less than would be required theoretically for the highest speed travel, and too great for the slower speeds.

**Vertical Curves.** Because of the simplicity of the computations, parabolic arcs are used to connect intersecting

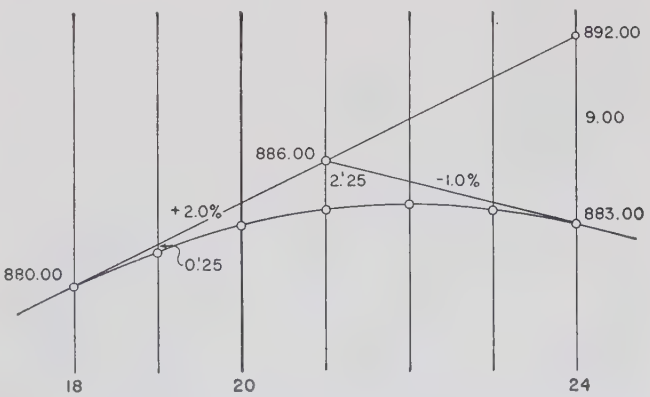

*Fig. 4—SURVEYING A PARABOLIC VERTICAL CURVE*

grade lines. From the properties of the parabola, the horizontal projections of the tangents to a parabola are equal, and the vertical offsets from a tangent to the parabola vary as the squares of the horizontal distances from the point of tangency. The computations for a parabola connecting the two grade lines shown in Fig. 4 are tabulated above. From the indicated rates of grade, the offset at the final Station 24 is computed at 9.00 ft. The offset from the tangent at the first station on the curve is $9.00/(6)^2 = 0.25$ ft.

COMPUTATIONS FOR FIG. 4

| *Sta.* | *Elev. Tangent* | *Offset* | *Elev. Curve* | *Offsets* |
|---|---|---|---|---|
| 18 | 880.00 | 0.00 | 880.00 | |
| 19 | 882.00 | 0.25 | 881.75 | $0.25 \times 1^2 = 0.25$ |
| 20 | 884.00 | 1.00 | 883.00 | $0.25 \times 2^2 = 1.00$ |
| 21 | 886.00 | 2.25 | 883.75 | $0.25 \times 3^2 = 2.25$ |
| 22 | 888.00 | 4.00 | 884.00 | $0.25 \times 4^2 = 4.00$ |
| 23 | 890.00 | 6.25 | 883.75 | $0.25 \times 5^2 = 6.25$ |
| 24 | 892.00 | 9.00 | 883.00 | $0.25 \times 6^2 = 9.00$ |

## MAPS AND MAPPING

**Map Scales.** A map is a graphical representation of a portion of the earth's surface, drawn on a plane to some definite scale. Maps are classed as large-scale when 1 in. on the map represents not more than 100 ft. on the ground. Between 1 in. = 100 ft. and 1 in. = 1,000 ft., the map is intermediate-scale. When 1 in. represents more than 1,000 ft., the map is a small-scale one.

Many maps and charts are plotted to so-called natural scales. These natural scales are represented by ratios. On a 1/20,000 map, one unit on the map represents 20,000 units on the ground. Thus, 1 in. on paper represents 20,000 in. on the ground, 1 ft. represents 20,000 ft., and 1 meter represents 20,000 m. on the ground.

A planimetric map is one that represents only horizontal positions. If vertical relations can also be determined, the map is a topographic one.

**Contours.** The most accurate method of depicting vertical positions is by means of contour lines. A contour line contains all points at the same elevation, and every point on a contour is at exactly the same elevation. The intersection of the surface of a still body of water with the shore represents a contour line. The vertical distance between successive contour lines is the contour interval. This may vary from 1 or 2 ft. on maps of very flat ground, to 20 or 100 ft. on those of rugged terrain. The character of the ground surface can be determined by an inspection of a contour map. Widely-spaced contours indicate relatively flat ground, whereas it is steeper where they are close together. If the lines are evenly spaced, the slopes are uniform. The scale of the map and the contour interval must, of course, be taken into consideration when deciding whether the ground surface is flat or precipitous.

**Stadia Surveying.** The stadia method is used almost universally for locating contours and in filling in detail when a topographic map is being made by ground surveys. By this method, both horizontal and vertical distances can be obtained from the same observations. The telescopes of transits and alidades are equipped with three horizontal cross wires, the upper and lower ones being called the stadia wires. The stadia measurement is made by noting the vertical distance intercepted on a rod between the stadia wires. If vertical angles are measured, differences of elevation can be calculated.

Stadia measurements are based on the similar triangles $ABF$ and $a'b'F$ in Fig. 5. Stadia wires placed at $a$ and $b$ in the telescope appear to intercept a rod at $A$ and $B$. Since rays of light that pass through the principal focus of the objective become parallel to the axis of the telescope, $ab = a'b' = i$, the vertical distance between the stadia wires. The focal length $f$ of the objective is the distance from the lens to $F$, the principal focus. The cross wires and the rod are at conjugate foci of the lens.

From the similar triangles,

$$\frac{R}{f} = \frac{AB}{a'b'} \quad \text{or} \quad R = \frac{f}{i} \times AB ,$$

where $R$ is the distance from the point of focus to the rod and $AB$ is the intercepted distance on the rod, the stadia interval of the telescope is the ratio $f/i$. Most instrument makers attempt to place the stadia wires to make this ratio equal 100, so that the distance from the principal focus to the rod will be 100 times the distance intercepted on the rod. The distance to the center of the telescope will be greater than the observed distance $R$ by an amount $C = c + f$. The value of this stadia constant is usually marked on a card attached to the inside of the instrument box. If it is missing, it can be determined by measuring $c$ and $f$ directly on the telescope.

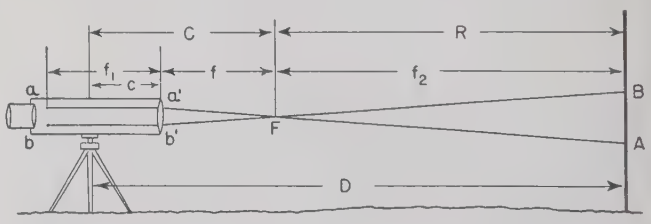

*Fig. 5—THEORY OF STADIA MEASUREMENTS*

Since the cross wires and the rod are at conjugate foci of the objective, $1/f_1 + 1/f_2 = 1/f$. The distance to the rod will be large compared with the length of the telescope, so $1/f_2$ will be quite small, and for all practical purposes $1/f_1 = 1/f$, or $f_1 = f$. The distance $f_1$ from the cross wires to the objective can be measured directly on the telescope, as can $c$, the distance from the objective to the center of the telescope. Their sum will be the constant $C$ for the instrument.

**Inclined Stadia Measurements.** When the line of sight is inclined, a correction must be applied to the observed distance to obtain the horizontal distance. The intercepted distance $AB$ in Fig. 6 will be too great, since the line of sight $ED$ is not perpendicular to the rod. In the triangle $ADA'$ the angle at $A'$ is practically 90°; $A'B' = AB \cos a$.

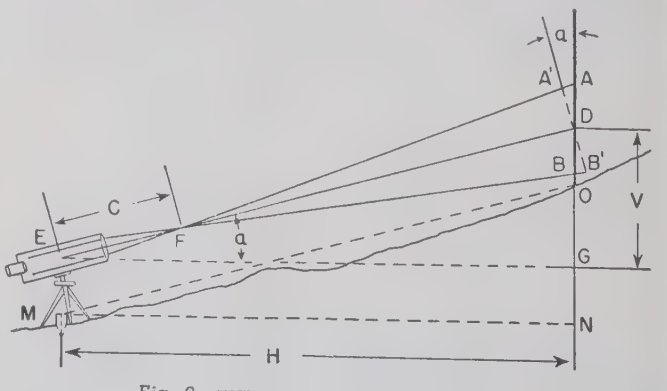

*Fig. 6—INCLINED STADIA MEASUREMENTS*

$ED = f/i \times AB \cos a + C = R \cos a + C$, where $R = f/i \times AB$. In the triangle $EDG$, $EG = H = R \cos^2 a + C \cos a = R - R \sin^2 a + C \cos a$; $DG = V = R \cos a \sin a + C \sin a = R \times \frac{1}{2} \sin 2a + C \sin a$.

When extreme precision is not required, the following formulas can be used:

$$H = R \cos^2 a + C = R - R \sin^2 a + C$$

$$V = R \times \tfrac{1}{2} \sin 2a.$$

If, in Fig. 6, $OD$ is made equal to $EM$ when the vertical angle $a$ is being measured, the triangles $EDG$ and $MON$ are equal, and $ON = DG = V$. Thus, the difference in elevation between the point occupied by the transit and the point where the rod is held is obtained directly.

The corrected horizontal and vertical distances can be calculated by a direct application of the formulas listed above, by means of stadia tables found in most engineering handbooks, by stadia slide rules, or by the use of stadia diagrams.

**Field Procedure.** The first step in a topographic survey is to establish horizontal and vertical control. When a survey is made of a very small area, it may be possible to make all the field measurements from a single position of the instrument. If the area is somewhat larger, the transit or plane-table stations can be connected by a closed traverse, the distance between them being measured by stadia or steel tape, depending upon the required precision. For very large areas, a triangulation network is required. Traverses are run between the triangulation stations to locate the transit or plane-table stations.

Vertical control may consist of a single bench mark or an extensive level network with enough bench marks to permit frequent checks on elevations to be made from the traverse stations. For very accurate work, the elevations of the stations may be determined by spirit leveling.

Contours are located in two ways. The more accurate method is to find points on the ground the elevations of which are those of the required contour. The points are so selected that when they are plotted on the map, a smooth curve drawn through them is an accurate representation of the contour. The points are found by trial in the same manner in which a grade stake is set. The elevation of the transit or level is found by a rod reading on a point of known elevation. The difference between this height of instrument and the elevation of the required contour is the rod reading to be found on the ground by trial. When the point is found, it is located by measuring a horizontal angle and a distance to it from some fixed point. This field procedure is best suited to surveys of small areas or where a small number of contours are to be located. In the second method, interpolation is used when the ground surface is very irregular and when many contours are to be located. In this method, the rodman picks points at which there are breaks in the ground surface. The instrumentman locates the points by reading a horizontal angle, a stadia distance, and a vertical angle to each of them. After the points and their calculated elevations have been plotted on the map, contours are drawn by interpolating along lines that join points between which the ground slopes are uniform.

**Plane-Table Surveying.** The plane table is used to prepare a map in the field where the features can be seen and errors readily detected and corrected. If the survey can be made from a single station, the plane-table board with drawing paper attached is set up, leveled, and oriented so the area to be covered will fall within the limits of the sheet. A point on the board is selected to correspond with the station on the ground, and pointings are made to objects which are to appear on the map and to points to be used in locating the contours. The pointings are made by pivoting the edge of the alidade over the mapped position of the station, and directing the telescope to the rod. The stadia distance and the vertical angle are measured. Without disturbing the alidade, the corrected horizontal distance is plotted along the edge of the ruler, and the calculated elevation of the point is indicated. When a sufficient number of points have been mapped, the corresponding features such as streams, highways, railroads, and buildings are drawn in and the contours are sketched. Because the ground surface is directly before the topographer, he can map the area with fewer located points than is possible when the transit-stadia method is used.

If a larger area is to be covered and more than one station is necessary, the additional stations may be located as the survey progresses. Upon moving to a new station, the alidade is placed along the line connecting the station with a previously occupied one and the board is turned until the line of sight strikes that point. The board is then clamped and its orientation is checked by sighting on another previously located point that is visible from the new station. The area within the limits of this station is mapped and another new station is then located. The work should be conducted so that the plane-table stations form a closed traverse, thus affording a check on the precision of the survey. When large areas are being mapped, errors of closure in the traverses are difficult to distribute. It is preferable, in this case, to establish control by more exact methods, such as triangulation or taped transit traverses. This control is plotted on the plane-table sheet before taking it into the field.

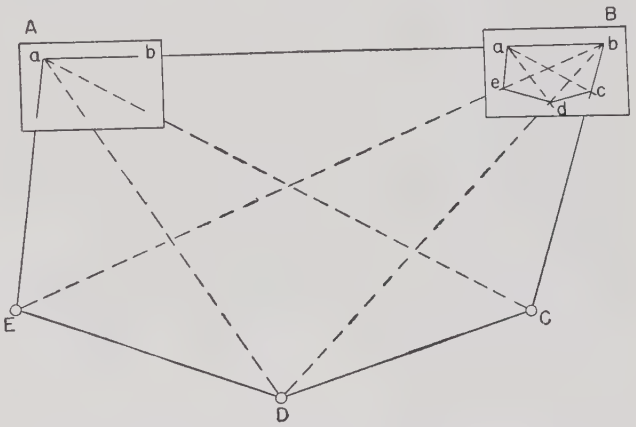

*Fig. 7—The principles of intersection, by means of a plane table*

**Method of Intersection.** The principles of intersection are shown in Fig. 7. In this example the board is set up at Station $A$ and oriented. Station $B$ is located by sighting to it and measuring the distance $AB$. From $A$, pointings are made on points $E$, $D$, and $C$, and lines are drawn on the map to indicate their directions. The board is then moved to Station $B$ and oriented by backsighting on Station $A$. Sights are again taken on points $E$, $D$, and $C$. The mapped positions of these points are at the intersections of the lines from Station $B$ with those drawn from Station $A$. These points may represent additional plane-table stations to be occupied later, or they may be points difficult or impossible of access by a rodman. Their elevations can be calculated by measuring vertical angles to them, and by scaling from the map the horizontal distances to them. The difference in

elevation is the product of the horizontal distance and the tangent of the vertical angle.

**Three-Point Problem.** An additional advantage of the plane table is the ease with which the three-point problem can be solved. If, in Fig. 8, points *A*, *B*, and *C* are visible from a point *P*, and if these points have previously been plotted on the plane-table sheet, the plotted position of *p* can be determined and the board properly oriented.

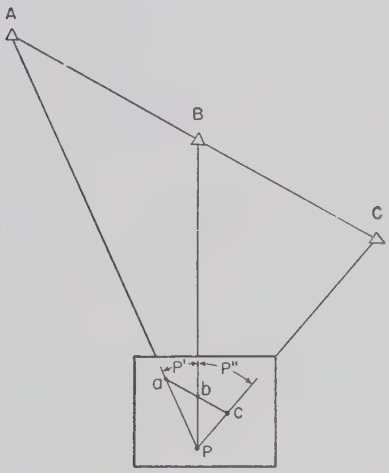

*Fig. 8 — SOLUTION OF THE THREE-POINT PROBLEM*

A mechanical solution of the problem requires a piece of tracing paper. This is placed on the plane-table board, and from any convenient point on it radial lines are drawn in the directions of the three points *A*, *B*, and *C*. The paper is then shifted until the line toward *A* passes through *a* on the board, the one through *B* passes through *b*, and the one through *C* passes through *c*. The intersection of the three lines is then directly above *p* on the board, and its position can be marked by pricking through the transparent paper to the map below. The board is then oriented by placing the alidade along the line *pa*, *pb*, or *pc* and rotating the board until the line of sight passes through the corresponding point on the ground. The orientation can be checked by sighting at either of the other two points.

The point *p* can also be determined by trial. After the board has been oriented by estimation, the alidade is pivoted over *a*, a sight is taken on *A*, and a line is drawn along the edge of the alidade. It is next pivoted over *b*, a sight is taken on *B*, and a line is drawn to intersect the first one. If the board has been correctly oriented, the line through *c* with the alidade pointing on *C* will intersect the first two lines in the same point. If not, as is generally the case, a triangle will be formed. From the size and shape of this triangle it is possible to estimate the approximate amount the board should be rotated. Successive trials are made until this triangle of error is reduced to a point.

The three-point method of location is valuable when areas on both sides of a stream are being mapped and where it has not been convenient to locate in advance a station on the opposite bank. It also affords a means of orientation when an older map is taken into the field for checking or revision.

## GEODESY

**Definition and Scope.** Geodesy is that branch of surveying which takes into account the size and shape of the earth. The work includes the determination of the size and shape of the earth as well as the exact position of points on its surface. These tasks require astronomical observations for time, latitude, longitude, and azimuth; triangulation, including the measurement of the force of gravity, terrestrial magnetism, and the deviation of the plumb bob; leveling; and sounding of oceans, lakes, and rivers, which in turn necessitates the determination of mean sea level, and a study of tides and currents. These measurements are subject to certain unavoidable errors. After all known errors have been eliminated, the method of least squares is used to determine the most probable values of the observed quantities.

**Triangulation.** If the length of one side of a triangle and at least two of its angles are known, the lengths of the other two sides can be computed. In geodetic work, most lengths are obtained in this manner, since direct measurement by taping would be too laborious. Long belts of triangulation, consisting of connected quadrilaterals, have been carried across the country. Although positions could be calculated if connected triangles were used, there would be fewer checks on the precision of the work. For this reason, quadrilaterals, or figures with a common center point, are used, and all angles are obtained by observation. At intervals, a side, called a base line, is measured on the ground.

*Classes of Triangulation.* Triangulation is classed as first, second, third, or fourth order according to its precision. Certain specifications have been set up to test this precision. As an example, in first-order work, the sum of the three angles of a triangle should usually be within 1″ of the theoretical 180°, and never more than 3″ in error. The corresponding values for fourth order are 12″ and 30″. The actual error in the length of a first-order base line should not exceed 1 part in 300,000, and the probable error should not exceed 1 in 1,000,000. The fourth-order values are 1 in 25,000 and 1 in 100,000. A further test is to compare the computed length of a check base line with its measured length. For the first-order precision, the discrepancy should not exceed 1 in 25,000. For fourth-order work, 1 in 2,500 is allowable. *See also* COAST AND GEODETIC SURVEY, UNITED STATES; MAPS AND CHARTS; PHOTOGRAMMETRY. H. Bo.

**SUSA,** a famous ancient city of western Asia and the capital of Elam. Susa is mentioned in Biblical narrative as Shushan, the "city of lilies." A stele found there and dating from late in the third millenium B.C. records the victories of Naram Sin, King of Akkad. The city was captured by the Persian king Cyrus in the sixth century B.C., and Darius I made it the capital of Persia, building there a great palace. The Royal Road, 1,500 mi. long, ran from Susa to Sardis in Lydia. Susa, along with the rest of Persia, fell to Alexander the Great, and under the Seleucid kingdom the city was known as Seleucia-on-the-Eulaeus; although later subject to Parthia, it long remained within the sphere of Greek culture. The ruins of the palace of Darius are most impressive, and a great number of inscriptions and friezes have been found there. G. E. D.

**SUSANNA, HISTORY OF,** a book of the Apocrypha. It is found only in the Greek Bible and in versions based on it. Constituting an addition to the Book of Daniel, it precedes the first chapter of that book in most manuscripts in which it appears; in the Vulgate it is appended to the end of the Book of Daniel. Many critics suppose that the book was originally written in Aramaic rather than in Greek, but opinion is divided on this point.

The story of Susanna takes place in Babylon in the early days of the captivity. Susanna, the beautiful and virtuous wife of Joakim, is spitefully accused of adultery by two elders who had failed in their attempts to seduce her, and on

the strength of their testimony she is condemned to death. Convinced of her innocence, however, Daniel, then a young man, cleverly exposes the falsity of the accusation by cross-examining each of the elders separately.

The History of Susanna was probably composed in the early part of the first century B.C. Bible critics do not regard the story as historical, but some see it simply as an additional Daniel legend, while others believe that it was written, in a period of legal reform, to demonstrate the necessity for thorough cross-examination of witnesses. D. G.

**SUSARION** [susɛ′əriən], Greek comic poet supposed to have lived in the sixth century B.C., shares with other claimants the reputation of having invented comedy as a literary form. According to most ancient sources, he came from Icaria in Attica; a late Byzantine story that he was a Megarean may have arisen from the tradition that comedy originated in Megara. The one fragment preserved from his work is of doubtful authenticity: according to the story Susarion entered the theatre, when his wife deserted him, and recited the following verses: "Hear ye, O people: thus speaks Susarion: Women are a nuisance. But still, my neighbors, one cannot keep house without a nuisance." From such impromptu utterances comedy was supposed to have taken its origin. Many have doubted that Susarion ever existed.
C. T. M.

**SUSQUEHANNA.** *See* INDIAN TRIBES, NORTH AMERICAN (*Eastern Woodland*).

**SUSQUEHANNA RIVER** [sʌskwəhæ′nə], the largest river of Pennsylvania, 444 mi. in length. It rises in Otsego Lake, northeast of Cooperstown, Otsego Co., east central New York State, and flows southwestward into Chenango Co., N. Y., where it bends southward into Susquehanna Co., northeastern Pennsylvania. The river then bends northwestward into south central New York State, where it turns to the south again and flows into Bradford Co., Pa. After flowing southeastward to a point near Pittston, Pa., the river bends to the southwest and eventually joins the West Branch of the Susquehanna just to the north of Sunbury, in east central Pennsylvania. The headwaters of the West Branch rise in Indiana Co., west central Pennsylvania, and the river flows generally northeastward to Lycoming Co., where it bends to the south to join the Susquehanna proper. The West Branch of the Susquehanna is 160 mi. long. From Sunbury, the Susquehanna River flows southward and southeastward across Pennsylvania and into northeastern Maryland, where it enters Chesapeake Bay near Havre de Grace, Md.

Before the Ice Age the Susquehanna drained most of central New York State, but the ice deposited a moraine across the state and the northern tributaries of the Susquehanna were blocked and formed the Finger Lakes. The North Fork and West Branch were formerly separate rivers, but tributary streams of the West Branch captured the North Branch, diverting the water into the course of the West Branch. Between Sunbury and Harrisburg, Pa., the Susquehanna has cut five water gaps across the Appalachian.

The Susquehanna is a shallow, rapid stream that becomes a raging torrent in late winter. The North Fork falls 1,923 ft., while the West Branch falls 688 ft. The Susquehanna flows through the Scranton-Wilkes-Barre anthracite coal-mining and industrial sections. The most important cities on the river are Binghamton, N. Y., and Pittston, Wilkes-Barre, Harrisburg, and Lancaster, Pa. From the mouth of the Susquehanna there is a submarine channel that extends eastward across the continental shelf. J. E. F.

**SUSQUEHANNA UNIVERSITY,** an accredited, co-educational college of arts and sciences, affiliated with the United Lutheran Church in America. It occupies a 62-acre campus in Selinsgrove, Pa. It was chartered as the Missionary Institute of the Evangelical Lutheran Church in 1858 and first instruction was given that same year. The present name was adopted in 1924, when the institution was changed from a two-year to a four-year college. The degrees offered include the A.B., the B.S., and the B.Mus. Courses are offered in teacher training and in business education. Some undergraduate scholarship aid is offered and some opportunity for self-help. Dormitories are available for both men and women. *For statistics see* COLLEGES AND UNIVERSITIES.
J. R. To.

**SUSSEX,** a maritime county in southeastern England, with an area of 1,457 sq. mi. It is bounded by the counties of Surrey and Kent on the north, Hampshire on the west, and by the English Channel on the east and south. The chalk uplands of the South Downs extend from the Hampshire border along the coast as far as Beachy Head. North of the Head is the Weald valley, from which the surface rises to a forest ridge in the northeast and sinks toward the sea in the southeast, where there are wide marshes. Sussex is divided into the administrative counties of East Sussex and West Sussex. At Lewes the assizes for the whole county sit, as does the county council for East Sussex, but the county council for West Sussex is at Chichester, a cathedral town which still shows traces of its Roman origin. The most fertile soil is near the coast, where grain and hay are raised. The South Downs are pastoral and have given their name to a breed of sheep. Hops are grown in the eastern part of the county. Ironstone is abundant. Woolens, paper, gunpowder, and bricks are manufactured. The Weald, once densely forested, is now denuded and is used as a pasture. There was an important iron industry on its heights in the sixteenth and seventeenth centuries. Hastings was one of the Cinque Ports—that is, the five great ports on the southeastern coast. The Battle of Hastings, 1066, was fought about seven miles northwest of the town. Rye and Winchelsea were "Ancient Towns," sharing the privileges and duties of the Cinque Ports. Brighton is the largest and most widely known seaside resort in England. Christ's Hospital, West Horsham, is the famous Blue Coat School, where the students still wear the ancient costume with blue gowns. Charles Lamb, Samuel Coleridge, and Leigh Hunt were among its graduates. The county returns seven members to Parliament. Pop. 1954, 937,200.
S. Van V.

*Pevensey Castle, Sussex, one of the remaining Norman ruins of the area*

THE TRAVEL ASSOCIATION

**SUSSEX,** a town in Kings Co., New Brunswick, Canada, situated in the valley of the Kennebecasis River, 40 mi. northeast of St. John on Provincial Highway 2. Sussex is served by the Canadian National Railways. It lies in the midst of one of the better agricultural districts of the province, noted for its dairy cattle. Pop. 1951, 3,224. D. F. P.

**SUSSEX SPANIEL.** *See* Dog.

**SUTHERLAND** [sʌ'thərlənd], a maritime county of northern Scotland with an area of 2,028 sq. mi. It extends from sea to sea, bounded on the west and north by the Atlantic Ocean, on the east by Caithness and the Moray Firth, and on the south by Dornoch Firth and Ross and Cromarty. The county is mainly mountainous, with heaths and bogs, trackless deer forests, and barren grouse moors. It has a larger proportion of surface covered with water than any other Scottish county. Ben More Assynt, the county's highest peak, rises to 3,273 ft. There are extensive coast fisheries. The dukes of Sutherland are the principal landowners. At the Sutherland Clearances of 1810-1820 about 15,000 peasants were moved from the crowded interior crofts to crofts on the coast. Sutherland unites with Caithness to send one member to Parliament. It is the most sparsely populated county in Scotland. Pop. 1954, 13,519. S. Van V.

**SUTHERLAND FALLS,** the highest waterfall in New Zealand, 1,904 ft. in height, and one of the highest waterfalls in the world. The falls are located in the mountainous southwestern part of South Island and are formed by a stream, the outlet of a small glacial lake, which plunges over a high precipice to the floor of the Arthur Valley. The Arthur River empties into Milford Sound, formed by one of the many indentions of the western coast of the island. R. G. B.

**SUTTER, JOHN AUGUSTUS** (1803-1880), American pioneer, was born in Kandern, Baden, Germany, in February 1803. He passed his early years in the village of Ruenenberg, Switzerland, and attended a military school at Neuchatel. He served in the Swiss army and, in 1834, emigrated to America; he may have lived for about a year at St. Charles, Mo. In 1835 and 1836, he traveled in the southwest, and in 1838 he went to Oregon. From there he sailed south to San Francisco Bay, in July 1839, and four days later, at Monterey, he presented to the Mexican governor, Juan Bautista Alvarado, a project for establishing a colony on the unexplored frontier at the north. He selected a tract on the site of the present city of Sacramento, Calif., where he constructed a fortified post that he named Nueva Helvetia. In 1841, he received a formal grant from the Mexican government of this tract, of between 100 and 150 square miles, and became that year a Mexican citizen. In 1849, he was a delegate to the Constitutional Convention of the new state of California and a candidate for governor at the first election. Meanwhile, on Jan. 24, 1848, gold was discovered on his property. In the California gold stampede of 1848 and 1849, his workers deserted him and his flocks and herds were stolen. In 1852, he was bankrupt. Seven years before he had been the owner of a vast estate and the virtual ruler of an independent domain. The remaining years of his life were spent in futile efforts to recover these lost properties. He died at Washington, D. C., June 18, 1880. A. W. Gr.

**SUVA** [su'və], the capital of the Fiji Islands, a British colony in the south Pacific Ocean. Suva is located at 18° 8′ S. lat. and 178° 25′ E. long. on the southern coast of Viti Levu Island. The city is 2,740 mi. south southwest of Honolulu, Hawaii, and 1,743 mi. northeast of Sydney, Australia. Suva is noted for its beautiful harbor, one of the best in the South Pacific. Suva has a tropical oceanic climate with year-round temperatures averaging between 70° and 80° F. The capital of the Fiji Islands was transferred to Suva from Levuka, on the island of Ovalau, in 1882, and since that time Suva has developed rapidly. During World War II Suva was a valuable base and port of supply. Pop. 15,000. R. G. B.

**SUWANNEE** [suwɔ'ni; swɒ'ni], one of the largest rivers in the southeastern part of the United States. The Suwannee, 190 mi. long., is formed by the junction of the North and Log rivers in Charlton Co., Ga. From this point it flows southwestward to the Florida boundary at Bounts Ferry, then flows nearly due south, loops westward, and resumes its southern course to empty into the Gulf of Mexico at Suwannee Sound, located about 12 mi. north of Cedar Keys. The Suwannee receives a number of small tributaries. In its upper reaches, the river has a fairly steep gradient and flows swiftly in a relatively narrow valley, hemmed in by high wooded banks, but further downstream it widens and flows through a broad flood plain. During the eighteenth and nineteenth centuries, the Suwannee was of considerable importance as an outlet for cedar logs floated downstream and later carrying considerable steamer traffic. At the turn of the century, however, river traffic ceased as a result of railroad competition. The importance of the Suwannee today for most Americans lies probably in the fact that it is mentioned in Stephen Foster's "Old Folks at Home." A. L. R.

**SVALBARD** [svɑ'lbɑr], all the Norwegian island possessions in the Arctic north of Norway, between 74° and 81° N. lat, and between 10° and 35° E. long., including the islands and island groups of Spitsbergen, Bjørnøya (Bear Island), Hopen (Hope Island), Kong Karls Land, and Kvitøya, with a total area of about 24,500 sq. mi. Spitsbergen, the principal group, comprises five major islands and many smaller ones; it measures approximately 250 mi. both from north to south and from east to west, between 76° and 80° N. lat., and has a total area of 24,200 sq. mi. Vestspitsbergen, the largest island, has nearly 15,000 sq. mi. Nordaustlandet (North East Island), to the northeast, about 6,000 sq. mi.; Barentsøya (Barents Island), to the east, 580 sq. mi.; Edgeøya (Edge Island), south of Barentsøya, 2,500 sq. mi.; and Prins Karls Forland, to the west, about 300 sq. mi. The topography of the group is highly broken with the pointed mountain peaks (*spitsbergen*) for which it is named; of these, Newton Peak (5,676 ft.), on Vestspitsbergen, is the highest. Much of the surface of the larger islands is covered with tremendous glaciers which reach down to the ocean, where their ice breaks off (calves) into icebergs. The coasts are indented by deep fjords; Isfjorden, the longest, extends 60 mi. into the western part of Vestspitsbergen. The rivers, rushing in the summer, when the snow lying at elevations up to 1,600 ft. melts, are of little importance, since the greater part of the limited precipitation (about 10 in. annually) reaches the sea in the form of glacier ice. The vegetation is of the tundra type, principally mosses, with some 130 species of flowering plants and a few dwarf trees. The climate is arctic, with winter temperatures of —10° to —40° F. and summer temperature of 40° to 45° F.

The islands are part of the belt of mountains folded in the Silurian-Devonian and extending in a great arc from Scotland to Greenland. Bordering this belt of Paleozoic metamorphic rocks are two north-south belts of Archean

and Cambrian rocks. This complex of rocks was eroded to sea level in Tertiary time and later uplifted to 2,000 to 3,000 ft. where the flat plateau surface, or peneplain, is now found. During the Pleistocene the great plateau glaciers were formed, the remnants of which still exist.

Spitsbergen, discovered by the Norsemen in 1194 and rediscovered in 1596 by the Dutch navigator Willem Barents, was the scene of extensive whaling and sealing operations during the eighteenth and nineteenth centuries. The whales have become exterminated and the seals are greatly reduced in number, as are the native walruses, polar bears, reindeer, and foxes. Various birds, including the eider duck and gulls, frequent Svalbard, but only the ptarmigan and the snowy owl stay there throughout the year.

Coal has been mined commercially since 1899, when an American company began to exploit the Tertiary coal found to the south of Isfjorden. Its settlement, Longyear City (called Longyearbyen since 1916, when the mine passed to Norwegian ownership), is the largest in Svalbard, with a population of about 1,000. Another thousand or more miners live at other settlements, among them Ny Ålesund, Hiorthomn, Barentsburg, and Calypsobyen, all on the west coast of Vestspitsbergen, and Tunheim, on Bjørnøya. There is no native population. Shipments of coal totaled 336,500 long tons in 1947 and 422,785 long tons in 1948.

Prior to 1920 the islands had been without sovereignty, but in that year they were assigned to Norway by international agreement. This sovereignty, which excludes the fortification of the islands and guarantees equal opportunities to signatories of the treaty to engage in the islands' economic exploitation, was made operative on July 17, 1925. Many of the coal mines are worked by the Soviet government, to which, in accordance with the treaty, the Norwegian government refused to grant military bases at the end of World War II. J. E. V.

**SVANETIAN.** *See* Asiatic Tribes (*Other Linguistic Families*).

**SVENGALI** [svɛngɑ′li], the villain of George du Maurier's novel, *Trilby,* who is celebrated for his power of hypnosis. While under his spell, the unskilled heroine, Trilby, is transformed into a great singer. Hence, in general usage, a "Svengali" is a person who imposes his will and plans upon a weaker person. H. H. Wa.

**SVERDLOVSK** [svyɛrdlɔ′fsk], the name of both a governmental region and the city that is the administrative seat of that region, located in the Russian Soviet Federated Socialist Republic, in the west central Soviet Union.

**The City.** The city of Sverdlovsk was called Ekaterinburg prior to 1924. It is an industrial and mining center, located on both banks of the Iset River, near its source, in the eastern foothills of the middle Ural Mountains, about 190 mi. southeast of Molotov, at 57° 5′ N. lat. and 60° 30′ E. long. Founded by Peter the Great in 1721 and named after his wife Catherine I, it rapidly became a mining and trading center. It became especially famous for its cutting of gem stones. It figured significantly in the civil war between 1917 and 1921, and Tsar Nicholas, his wife, and five children were executed in a cellar there in July 1918. Under Soviet five-year plans it expanded enormously and developed further during World War II. It is a well-built city with wide streets and has two cathedrals and an old mint. Sverdlovsk possesses a state university, institute of medicine, institute of forestry, several repertory theatres, and numerous other educational and scientific institutions. It is the junction for seven important rail lines and is a distributing point for machinery and industrial raw materials. It is located in the rich Urals mineral area, and the local populace engages in the mining of gold, platinum, iron, manganese, bauxite, and asbestos. As the center of this great industrial area, which from 1925 to 1945 was made one of the world's largest, Sverdlovsk has a large variety of important industries. Products include steel, turbines, rolling stock, refined aluminum, electrical equipment, heavy machinery, roller bearings, rubber products, plastics, paper, refined copper, lathes, chemicals, machine tools, textiles, mining machinery, and precision instruments. Pop. (est. 1954), 750,000. C. C. H.

**The Region.** The Sverdlovsk Oblast (Region) adjoins the Khanty-Mansy National Okrug on the north and east, the Tyumen Oblast on the east, the Kurgan and Chelyabinsk oblasts and the Bashkir Autonomous Soviet Socialist Republic on the south, and the Molotov Oblast on the west. Its area of 74,556 sq. mi. was organized in 1934. Although the Central Urals, attaining a height of only 980 ft., level themselves out in the Sverdlovsk Oblast so that the terrain is an open one of wide valleys, emphasis is less on agriculture than on industry. Approximately 60 per cent of the total population in 1939 lived in cities, making the region one of the Soviet's most urbanized. The reason for this is the wealth of mineral resources either found in the region or easily accessible to it through the network of railroad lines which focuses on the city of Sverdlovsk. Copper ore is excavated at Pyshma and processed at Krasnouralsk and Revda; important sulphur works are found in Kirovgrad; bauxite occurs at Serov (formerly Nazhdedinsk); gold at Berezovsky; platinum at Nizhniy-Tagil; and coal at Ivdel, Alapayevsk, Serov, Kushva, and Nizhniy-Tagil. Fifty-eight per cent of the region is forested, supporting a lumber industry which is centered in Tavda, Novaya Lyalya, and Turinsky. In the valleys of the Tavda, Lozva, Pelym, Tura, and Iset rivers high yields of rye, wheat, and oats are secured. Cattle-breeding is increasing in importance. Although most of the population is Russian, a sizable minority of Germans is to be found, for it was here that the residents of the German Volga Autonomous Soviet Socialist Republic were transported in 1941-1942. Pop. (est. 1954), 3,500,000. W. S. V.

**SWABIA** [swe′biə], a stem duchy of medieval Germany. Deriving its name from the Suevi, it was situated in the valleys of the upper Rhine and the Neckar and around Lake Constance. Settled by various German tribes besides the Suevi, it was for a long time called Alamannia. It became a duchy of the Frankish kingdom after its conquest by Clovis in 496 but had to be reduced again by Charles Martel in 730. Swabia was ruled by the counts of Raeti until 917, when Count Burkhard took the title of duke, later receiving recognition from Henry the Fowler. On Burkhard's death in 926, a Franconian noble named Herman married his widow and secured the duchy. Herman died in 948 and Otto the Great gave the duchy to his son Ludolph, who later revolted and was deposed. After a succession of dukes, Swabia was given by Henry IV to Count Frederick of Hohenstaufen (1079), and it remained under Hohenstaufen control until the extinction of the line in 1268. Subsequently, the duchy fell apart into such states as Württemberg, Baden, and Hohenzollern. F. C. H.

**SWABIAN LEAGUE** [swe′biən], several associations of Swabian cities, nobles, and prelates in southwestern Germany, beginning in the fourteenth century, formed for re-

gional peace and the protection of commercial interests. In 1331, Ulm, Augsburg, Heilbronn, and nineteen other cities formed a league at the instance of the emperor, Louis IV of Bavaria, who wanted their support. Following defeat of the league in 1372, in 1376 a new federation of fourteen Swabian cities was formed for protection of their interests against the feudal nobles and the emperor Charles IV. Growing rapidly in numbers, the league maintained a large armed force and waged war with the opposing leagues of nobles. Peace was made after the defeat of the cities in 1388, and the leagues were dissolved.

A century later, in 1488, another Swabian League was formed to maintain order in the weak German empire. Many cities, nobles, and churchmen joined, with the approval of the emperor. The league had a formal constitution, a court, and a large army, which was used to support imperial reform. It restored order in Swabia, successfully opposed the aggressions of the dukes of Bavaria and Württemberg, and aided the Hapsburgs in putting down the revolt of the knights in 1523 and of the peasants in 1525. The league was dissolved early in 1534, due in part to internal divisions resulting from the Protestant Reformation. Later attempts made to renew it proved futile. F. C. H.

**SWALLOW,** any one of a large number of species of songbirds united in the family Hirundinidae. They occur in temperate and tropical regions virtually throughout the world. They are characterized by slender bodies, long, pointed wings, large mouths for capturing insects in flight and small, weak feet; the most typical swallows have deeply forked tails. The majority of them vary in size between 5½ and 8 in. Their plumage combines in various ways such colors as black, white, rufous, metallic blue, and metallic green. Owing to a similar mode of life, they have developed many characteristics in common with the swifts, to which they are not at all closely related; they fly, however, with a slower wing beat, rarely soar, and, despite their weak feet, frequently perch on wires and trees. The voices of swallows are twittering and unmusical. Their breeding habits are exceedingly variable: some nest in burrows or in crevices of stone walls, some in hollow trees; others breed under the eaves of buildings; still others affix retort-shaped structures of dried mud to such vertical surfaces as walls and cliffs. No less than nine species of swallows are known in the United States; of these, perhaps the best known are the barn swallow and the purple martin. H. G. De.

*THE TREE SWALLOW*

HAL H. HARRISON

**SWALLOWTAIL,** the name given to any butterfly of the genus *Papilio,* which includes most of the members of the family Papilionidae. The genus is a moderately large one, with most of its members occurring in the tropics. The swallowtails are divided into several distinct groups which are more or less associated with their feeding habits. In eastern North America, the best known species are the tiger swallowtail, *Papilo glaucus,* or *turnus,* which feeds on cherry and related plants; the parsley swallowtail, which feeds upon carrots and related plants; and the spicebush swallowtail, which feeds on sassafras, spicebush, and laurel. *P. daunus,* of the West, also feeds on cherries and related plants. The caterpillars of some species have eye-like spots on the thorax, and some possess a pair of extensile, tentacle-like scent organs which they extrude when disturbed. The orange dog is the caterpillar of *P. cresphontes,* the orange-tree swallowtail. The family includes the birdwing butterflies of New Guinea, the males of which have very narrow wings and the females of which are among the largest of all butterflies. These are sometimes placed in a separate genus, *Ornithoptera.* C. H. Cu.

**SWAMMERDAM, JAN** [svɑ'mərdɑm] (1637-1680), Dutch naturalist and biologist, born at Amsterdam, Feb. 12, 1637. He was the son of an apothecary, who had collected a museum of curiosities. He helped his father, entered the university of Leyden at 24, studied medicine and obtained his doctor's degree in 1667. He abandoned medicine for zoology, visited Paris and drew the attention of scientists by his skill in dissection. On his return he published *Algemeene Verhandeling von bloedloose diertjens* ("General Account of Bloodless Animalculae"—Utrecht, 1669; French and Latin versions, 1685), which deals with metamorphosis of insects. The text and illustrations won popular recognition, particularly because of the minuteness of observation and intelligent presentation. In 1664 he discovered the valves of the lymphatic vessels. Swammerdam observed and described (1658) blood corpuscles in the frog. He traced the development of the frog and made fine dissections of the tadpole. Swammerdam demonstrated by an experiment that when muscles contract they alter in form but not in size. He studied infections and the movement of the heart and lungs. He improved the technique of injection; and one of his early publications threw some light on respiratory processes. He depicted the sporangia of ferns and investigated the anatomy of the May fly, the bee, the snail, and other forms. He came under the influence of a religious fanatic and suffered fits of depression. In this state he wrote *Ephemerae vita* (Amsterdam, 1675) containing examples of minute anatomy of the May fly. He bequeathed his drawings and manuscripts to Thevenot. On Thevenot's death they were sold by his heirs. His *Biblia Naturæ* ("Bible of Nature") was published in 1737-1738 with plates in two folios. Swammerdam died at Amsterdam Feb. 15, 1680. D. D. M.

**SWAMP LILY,** a handsome perennial, *Crinum americanum,* of the lily family, bearing several creamy-white to greenish flowers on an erect stalk about 2 ft. high. The leaves are 2 to 4 ft. long and are curved and narrow; the whole plant rises from a thick-coated bulb. The swamp lily is also called the St.-John's-lily and is sometimes grown for ornament, but it is native to river swamps from Florida and Georgia westward to Louisiana. M. G. W.

**SWAMP PINK,** *Helonias bullata,* a rare and attractive member of the lily family, inhabiting acid bogs of the coastal plain from southern New York perhaps as far south as

Virginia. It grows as high as 2 ft. The small pink flowers, which have blue anthers, are borne in a dense terminal raceme. They are hyacinth-scented. Increasing readily under favorable conditions, the swamp pink is one of the most desirable of plants for northern bog gardens. C. H. Wo.

**SWAMPSCOTT** [swɒ′mpskət], a town in northeastern Massachusetts, situated in Essex Co., on Massachusetts Bay, between Lynn on the southwest and Marblehead on the northeast, 12 mi. north of Boston, of which it is a suburb. Founded in 1629, Swampscott was incorporated as a town in 1852. The local government is the representative-town-meeting type. Two features of special interest are the Mary Baker Eddy House, where the founder of Christian Science began her demonstrations of healing; and the Humphrey House, built about 1635 and the home of the deputy governor of the Massachusetts Colony. Swampscott is supplied with transportation by the Boston and Maine Railroad. Commercial fishing is an important industry of the city. Pop. 1950, 11,580.

**SWAN, SIR JOSEPH WILSON** (1828-1914), English engineer and inventor, was born in Sunderland, Durham, Oct. 31, 1828. He had little formal education and was apprenticed early to a firm of chemists. He later joined another chemical firm, introduced new manufacturing processes, and in 1860 became a partner. In 1864 Swan developed the "autotype" carbon process, the first practical means for making permanent photographs. At the same time he developed a leather-curing process that became the basis for modern tanning methods. In 1877 he developed sensitive dry-gelatin plates and two years later bromide photographic-printing paper. Swan's work with electric bulbs led him to devise a longer lasting filament; this he did by treating ordinary crocheting cotton with sulphuric acid and then carbonizing it. Further experiments showed that the life of the filament depended to a considerable extent on the vacuum it burned in. The mercury pump invented in 1865 by Herman Sprengel achieved a superior vacuum and with it Swan produced a carbon-filament incandescent lamp in 1879. He also invented the miner's electric safety lamp. Swan was knighted in 1904. He died in Warlingham, Surrey, on May 27, 1914.
S. M. M.

**SWAN,** any one of five species of very large, long-necked, web-footed birds united in the genus *Cygnus;* they are closely allied to the geese. Three species breed in subarctic and temperate regions of the Northern Hemisphere; the others are restricted to Australia and southern South America. The plumage of the northern species is all white; the Australian swan is black with white wing patches, and the South American bird is white with a black neck. Male swans are known as cobs; the young are called cygnets. Most swans are famous for their loud, resonant voices. The mute swan, *C. olor,* is exceptional in being able to produce only hissing sounds. Of the two native North American species, the trumpeter swan, *C. buccinator,* has become extremely rare and restricted to a small number of breeding places in the western part of the continent, but the whistling swan, *C. columbianus,* is increasing in numbers under protection. The semidomesticated mute swan has been imported from Europe and is a familiar bird on park lakes. The trumpeter swan measures 5 ft. long and the whistling swan measures 4½ ft. H. G. De.

HAROLD M. LAMBERT FROM FREDERIC LEWIS

*Swan, constituting the subfamily Cygninae of the duck family*

**SWAN LAKE (LE LAC DES CYGNES)** [lə la′k de si′ny], a ballet to a score by Pyotr Ilyich Tchaikovsky. An unsuccessful version, with choreography by Julius Reisinger and with much of Tchaikovsky's music discarded in favor of conventional dance tunes, was presented at the Bolshoi Theatre, Moscow, on Mar. 4, 1877. In 1894 Marius Petipa sketched out a new version, for which the actual staging was done by Lev Ivanovich Ivanov. The second act was presented at the Maryinsky Theatre, St. Petersburg, on Feb. 29, 1894, and the entire four acts on Jan. 27, 1895.

Recent custom presents Act Two as a separate ballet. The *pas de deux* from Act Three, featuring the thirty-two *fouettés* made famous by Pierina Legnani in the first performance, is frequently presented separately as the *Black Swan Pas de Deux.* The full-length *Swan Lake* remains in the repertories of the English and Russian ballet companies. F. G. P.

**SWANSEA** [swɒ′nsi; swɒ′nzi], a residential suburb of Toronto in York Co., Ontario, Canada, along the Humber River. It was incorporated as a village in 1925. Large steel and clay products plants are located at Swansea. Pop. 1951, 8,072. D. F. P.

**SWANSEA,** a municipal, county, and parliamentary borough, railroad junction, and seaport of Glamorganshire, Wales, situated at the mouth of the Tawe River, on Swansea Bay, about 35 mi. northwest of Cardiff, in a coal-mining region. Henry de Beaumont conquered the area in 1090 and founded, at the end of the eleventh century, the castle around which the town developed. William de Braose granted the community its first charter in the last quarter of the twelfth century. Swansea, which became a parliamentary borough in 1832 and a county borough in 1888, returns two members to Parliament. The original castle, erected by De Beaumont, was destroyed in 1260, and was rebuilt by Bishop Gower. During the eighteenth century, coal was dug near Swansea and the first copper-smelting works were built in 1717. The Swansea Canal was opened in 1798, the Tawe was dammed in 1838, and the first of Swansea's docks was constructed in 1847. In 1850, the railroad was built. East of the Tawe, Swansea is one of the world's most important smelting centers, working in industrial and precious metals. Consequently, the city was heavily bombed in World War II. West of the river is the residential section and beach resort of Oystermouth, or Mumbles, where the remains of a castle, dating from the thirteenth or fourteenth century, are located. University College of Swansea is the newest of the four composing the University of Wales, and its departments of metallurgy and engineering are closely affiliated with the industries of the district, which include plants for copper refining, processing precious metals, manufacturing tinplate, steel plates, bars and tubes, superphosphates and patent fuel, and

the distribution centers for anthracite and oil. Pop. 1954, 160,400. S. Van V.

**SWAN THEATRE.** *See* ENGLISH PLAYHOUSES.

**SWARTHMORE COLLEGE** [swɔ′rthmor], an accredited, coeducational, privately controlled institution founded by members of the Society of Friends, but not now controlled by that Society. It is situated on a 250-acre campus in Swarthmore, Pa. The Bartol Foundation for Research in the Physical Sciences, located on the Swarthmore campus, is under the control of Franklin Institute. Degrees offered are the A.B. in liberal arts, the B.S. in various engineering curricula, and the M.A. The extensive library houses many important special collections, including the Friends historical library, the Jane Addams collection of documents dealing with efforts toward peace; and British Americana. Co-operative arrangements exist with all libraries in Philadelphia and the vicinity. The local chapter of Phi Beta Kappa was established in 1896.

Dormitories and dining halls are provided and residence on the campus is required except for those living in their homes or with relatives. Scholarships in substantial amounts are available, and there are no residential restrictions on these awards. There is also a loan fund. A limited number of opportunities for self-help enable some students to earn part of their expenses. Fraternities do not provide living accommodations. There are no sororities. *For statistics see* COLLEGES AND UNIVERSITIES. J. R. To.

**SWASTIKA,** an even cross, the arms of which are bent at a right angle. Since all four bars point in the same direction (either clockwise, or counter-clockwise) the form creates an impression of perpetual rotation.

The origin of the swastika is unknown. For thousands of years, it has been used as a symbol of the sun, of infinity, of continuing re-creation, as well as a decorative motive, in the Americas, China, Egypt, Greece, Scandinavia, and elsewhere. It has been found in the catacombs of Rome, on textiles of the Inca period, and on relics which were unearthed on the site of Troy. It is one of the sacred signs of Buddhism.

The connection with Buddhism probably made the swastika fashionable among some intellectually exclusive European groups at the turn of this century. For example, the books of the "Stefan George Circle" showed a swastika on their covers. At the same time, the sign began to be used by some groups of extremist Teutonic nationalists in Austria because of the mistaken belief that the swastika was of Indian origin and, therefore, following their race doctrine, an "Aryan" motif symbolic of their self-designated racial superiority.

According to one of Hitler's biographers, Konrad Heiden, some irregular German Free Corps who later formed the nucleus of the early Nazis, brought the swastika from Finland and Estonia where it was an official emblem, to Germany. In 1920, many troops wore the swastika on their helmets when they occupied Berlin in their abortive attempt to overthrow the German Republic. In his autobiography, *Mein Kampf,* Hitler claims, to have "laid down, after countless attempts, the final form" of the official Nazi flag: a black swastika in a white circle on red ground—red standing for socialism, white for nationalism—and the swastika, in Hitler's words, symbolizing "the fight for victory of Aryan man and of the idea of creative work, which in itself eternally has been anti-semitic and eternally will be anti-semitic." As Heiden said, the Nazi swastika emblem had "the effect of an iron octopus, a monster, aggressively reaching out in all directions—hence its menacing and frightening effect. In 1921, (it) . . . was unfurled in the open for the first time. The effect was so inflammatory that Hitler himself was surprised and pleased. In the swastika historical accident gave Hitler one of his mightiest magic weapons."

From March 1933, a few weeks after Hitler's ascent to power, the swastika flag had to be hoisted in Germany side by side with the national colors; from September 1935 until the downfall of the regime in 1945, it was the official flag of the Third Reich. The emblem was prominently displayed not only on all German military uniforms, airplanes, tanks, etc. but also on all public buildings, on German postal stamps, etc. In view of the strong identification of the swastika with National Socialism, after World War II Allied occupation authorities ordered its eradication from public view. J. H. E. F.

**SWATOW** [swɑ′tau′], a port on the estuary of the Han River, in Kwangtung Province, China, 170 mi. northeast of Hong Kong and 600 mi. southwest of Shanghai. Swatow is the outlet for Chaoan (Chaochow), 27 mi. to the north. The port was opened to foreign trade in 1858 by the Treaty of Tientsin with Great Britain, but the contact of Swatow with the Western world began about two centuries earlier. The first Westerners settled on Namao Island, just offshore from Swatow, trading in opium and kidnapping Chinese emigrants, who were destined for southeast Asia for sale in slave markets elsewhere. Many of the Chinese residents in southeast Asia and America came from Swatow. Swatow is noted for its grass cloth, fans, linen embroidery, and laces. Fishing is an important occupation. Refining of sugar constitutes the chief industry in the city, and the export of refined sugar amounts to 5,000,000 tons a year. The Swatow harbor measures 2.24 sq. mi., with depths of water ranging from 19.7 ft. to 65.6 ft. Averaging 71.6° F., the temperature at Swatow rises to 100.4° F. in summer and falls to 39.2° F. in winter. Typhoons occasionally hit the port. Annual precipitation ranges from 49 to 55 in. Pop. 1947, 180,000. J. E. F.

**SWAZILAND** [swɑ′ziland], a small British protectorate on the northeast border of the Union of South Africa, bounded on the east by Mozambique and Natal, and on the south, west, and north by the Transvaal. Swaziland, roughly oval in shape, has an area of 6,705 sq. mi. The western part of the region is traversed by high ridges and the general elevation there is about 4,000 ft. above sea level. In the eastern section of the protectorate the malaria-ridden lowlands lie about 500 ft. above sea level. Swaziland is covered by wide stretches of bushes and grassland. There are no forests. The whole area is drained by several rivers which flow into the Delagoa Bay region.

In 1953 the population totaled 207,000. At the 1946 census there were approximately 3,200 Europeans and a small group of mixed descent numbering 740. The largest native group, the Swazis, are a branch of the great Bantu race and are related to the Zulus. Mbabane, the capital of Swaziland, is situated in the west central section of the protectorate. The government is in the hands of a resident British commissioner assisted by an advisory council of nine members. He is responsible to the high commissioner for Basutoland, the Bechuanaland protectorate, and Swaziland, who is in turn responsible to the British secretary of state for commonwealth affairs. The small government revenue is

derived largely from an income tax, native tax, and customs and excise taxes.

Swaziland is not prosperous; much of the land is poor. Besides the chief crops of maize, cotton, and tobacco, there are small amounts of gold and tin. Asbestos is by far the major mineral produced, since lack of transportation prevents exploitation of rich anthracite deposits. The most important industry is cattle raising; nearly 500,000 cattle are pastured on the grasslands every year. In the grazing season, about 250,000 sheep are driven out of the Union of South Africa to the cooler climate of the high veld of western Swaziland. All transportation is by oxen or by truck and automobile. The general standard of living is low. There are several mission schools administered by various religious groups. The government also has an adequate number of primary schools, particularly important in native education.

In 1843, the Swazis won their freedom from the Zulus. The Swazis, unlike their native neighbors, became friendly with the Boers and with the British after the British occupied the Transvaal in 1877. Three years after the British withdrew from the Transvaal, the London Convention (1884) recognized the independence of Swaziland. Later, however, the Boers tried unsuccessfully to annex Swaziland. So great was the Boer pressure that the Swazis appealed to the British for help in 1886. During the gold rush of 1887 the Boer settlements in Swaziland increased considerably. In 1890 a dual British-Boer control over the area was finally established. This arrangement was unsuccessful, and in 1894 the administration of Swaziland was almost entirely taken over by the Transvaal. President S. J. P. Kruger of the Transvaal was anxious to press forward to the east coast, and hoped to obtain at Kosi Bay a seaport under Transvaal control.

When the Boer War ended in 1902 Swaziland fell into an anarchy that ended only with British annexation of the territory. Since 1906 Swaziland has been a British protectorate. About half the land is possessed by Europeans. The remainder is divided into native reserves. Despite frequent pressure from the Union of South Africa, particularly during the premierships of James B. M. Hertzog (1924-1939) and Daniel Malan (1948-1954), Swaziland has steadily refused to enter the Union, and the British authorities have taken no steps to end the separate existence of Swaziland as a protectorate.

G. S.

**SWEAT GLANDS.** *See* Mammal; Man, Functional Anatomy of (*The Tissues; The Cutaneous System*).

**SWEDEN,** a constitutional monarchy of northern Europe, occupying the eastern and larger portion of the Scandinavian Peninsula. It embraces an area of 173,394 sq. mi. or about 58 per cent of the peninsula and 4.7 per cent of all Europe; in area it is the fifth-largest European country. Sweden is somewhat smaller than France and nearly 50 per cent larger than the British Isles. It extends from 55° 20′ to 69° 4′ N. lat. and from 10° 58′ to 24° 11′ E. long. The difference in time between the Greenwich Observatory, near London, and the Stockholm Observatory is 1 hr., 12 min., and 14 sec. From north to south Sweden is nearly 1,000 mi. in length, and from east to west its greatest breadth is slightly more than 300 mi. Its boundaries have been estimated to aggregate almost 7,000 mi., of which slightly more than 4,700 mi. are coast and the remaining 2,300 mi. form the boundaries between Sweden and Norway on the west and Sweden and Finland on the northeast. For the greater part of its length the boundary between Sweden and Norway runs continuously along the ridge of the Kjölen Mountains (The Keel), which form the chief divide of the peninsula. The boundary with Finland is formed by the main channel of the rivers Köngämä, Muonio, and Torneå (Tornio).

## GEOGRAPHICAL FEATURES

**Geologic Movements.** Geologically, Sweden is a land of very ancient origin. By far the largest part of its surface is underlain by crystalline rocks formed in the earliest periods of the world's history. It is part of a very ancient massif, sometimes called Fenno-Scandia because the rocks of Finland and the Scandinavian Peninsula formed one of the most ancient continuous land masses or continents of which remnants are still preserved, like the Laurentian Shield of northeastern North America. Except for Skåne, the southernmost section of Sweden, which was partially submerged by the sea several times in the Mesozoic period of the world's geologic history, the main mass of the land of Sweden has persisted as part of one of the world's oldest continents, at least since early Silurian time. About 78 per cent of Sweden's area is underlain by Archean rocks; a little over 9 per cent is Algonkian; 12 per cent is Silurian, of which about half is metamorphic; and about 1 per cent is Mesozoic. The Archean rocks include granites, gneisses, porphyries, schists, phyllites, quartzites, leptites, and greenstones.

**Minerals.** *Iron.* Most of the valuable ore deposits are associated with porphyries and leptites. By far the largest and most important of such ore deposits are the iron ores of Lapland, in northern Sweden near the Finnish border, and those of Bergslagen, in central Sweden. In the Bergslagen district, which embraces western and northern parts of the province of Västmanland and adjacent parts of eastern Värmland and southern Kopparberg, a region long known as Dalarna, numerous deposits are worked. The Grängesberg field in southern Dalarna is considered most productive and most important of all the Bergslagen deposits. Several other iron deposits have yielded heavily in other parts of central Sweden: Dannemora and others in northern Uppland, Kantrop in Södermanland, and several in Östergötland. In the deposits of central Sweden the ore is found as layered masses,

*One of the oldest and most productive copper mines in the world is this one located near Falun, now an iron mine and foundry center.*

EWING GALLOWAY

in most cases intercalated in leptite rocks. Many of central Sweden's ore bodies have been worked almost continuously for centuries. Lapland deposits of much more recent discovery are remarkable for their great size and volume of potential ore. The largest of the deposits is at Kirunavara, veritably a mountain of magnetite in which the main ore body is more than 3 mi. in length and almost 500 ft. in thickness, enclosed between beds of porphyry. Other notable iron ore deposits in the northern or Lapland district are Gällivare, Luossavara, Tuollavara, and Svappavara. The ore throughout the district is preponderantly magnetite, mixed generally with apatite in lenticular masses; some such as Gällivare is included in leptites and gneisses. A third district of smaller size and quite different mineralogical character is that which includes the greater part of the large mountain, Taberg, situated in the province of Småland about 6 mi. south of Jönköping, where the ore is a low-grade mixture of titaniferous magnetite and olivine, a ferrous facies of a greenstone (hyperite) intrusion.

*Copper.* Copper is widely distributed throughout the mineralized section of central Sweden, but the only deposit now actively mined is near Falun, in the famous Bergslagen district, where a bed of chalcopyrite, one of the largest of that mineral in the world, has been mined for seven centuries. Other copper deposits which at one time or another have been important are at Garpenberg, in southern Dalarna; Tunaberg, in Södermanland; Bersbo, in Östergötland; and Areskutan in Jamtland.

*Other minerals.* Argentiferous or silver-bearing galena, of relatively little importance at present, has been mined at Nya Kopparberg, Guldsmedshyttan, and Kallmora, in Västmanland province, and at a few other places in the Bergslagen district. An important zinc blende, or sphalerite, deposit is worked in the Arumeberg zinc mines near Askersund; zinc ore is also mined at Ryllshyttan, Saxberget, and Stollberget, in Dalarna, and in the mines of Dannemora, in North Uppland. The rich silver mine, Sala, in the Bergslagen district, formerly so renowned for its high productivity, is almost exhausted. Manganese ore or pyrolusite has been mined in small quantities at Bölet, north of Karlsborg, and at Spexeryd and Hohult, south of Jönköping. Swedish granites are famous throughout the world for construction and for monuments; feldspar and quartz are derived from pegmatites prevalent in Archean rocks; and greenstone of distinctive character and quality is widely used and exported.

*Coal.* Sweden lacks coal except for three small districts in Skåne, aggregating about 300 sq. mi., and bearing moderately workable seams of coal from a foot to a little over a yard in thickness. The largest and northernmost of the three districts lies between Höganäs, Billesholm, and Landskrona; the central district is near Eslov railway junction and Stabbarp; and the southernmost district forms a narrow belt from Vombjön to the neighborhood of Ystad. Only the lowermost two seams are of quality and depth to warrant mining. Coal has been mined only from the northernmost district, where a low-grade variety has been brought to the surface in varying amounts, depending on the availability of foreign coal. Fire clay and shales for bricks, pipes, tiles, and other clay products are generally mined with the coal. Mines at Höganäs, Billesholm, Bjuv, Skromberga, Hyllinge, Ormantorp, and Gunnarstorp, and elsewhere in the northern district, have been most productive. The total coal production fills only a small part of Sweden's needs.

**Topography.** The whole of Scandinavia was covered with ice in the glacial epoch to a very great depth. At the time of its greatest extent, the ice sheet also covered Denmark, Finland, northern Germany, parts of Holland and Great Britain, and a large part of northwestern Russia; the North and the Baltic seas were solid fields of glacial ice. During the period of glaciation great areas of the ice-covered terrain were scoured and grooved. Huge deposits of rock materials, called till, were distributed irregularly in varying depths over practically all the land when the ice melted, and other deposits of silt, sand, gravel, and rocks were washed from the melting ice and assorted to form plains, terraces, and great serpentine ridges or eskers, called *Asar* by the Swedes, which are a widespread, distinctive feature in many parts of the country. The drainage pattern of the country was completely changed by the erosion and deposition that accompanied the glaciation, as well as by the sinking of large portions of the Scandinavian Peninsula under the weight of the ice and its subsequent rising when the ice melted away. The soils derived from the marine deposits when the land was submerged are the most productive and easily tilled in Sweden.

Sweden is separated from Norway by the great chain of the Kjölen Mountains, which form the backbone of the Scandinavian Peninsula. The eastern slope of this great massif drains almost entirely southeastward to the Baltic or, in its southern portion, southward to the Kattegat. The country may be separated into two major and distinctive natural regions, north and south, which have different features and arrangement of terrain, density of population, and cultural development. Northern Sweden, which also may be called the highland district of upper Sweden, includes the whole of Norrland, Dalarna, Värmland, and the northern part of Dalsland; southern Sweden includes all the rest of the country. Southern Sweden may be separated into three distinct subregions: the lowlands of central Sweden; the Småland highlands; and the plains of Skåne. Northern Sweden may be divided into three belts: the mountain and lake belt, the moraine and peat moss belt, and the marine and clay belt.

*Northern Sweden.* The mountain and lake belt of northern Sweden is a high, rocky slope toward Kjölen, transversed by wide, deep valleys in many of which long, narrow lakes have formed at elevations that vary by less than 300 ft. Their greatest depth is at their northwestern end. The divides between the numerous valleys form a moorland on which grow lichens, mosses, and a few flowering plants. The birch, *Betula odorata,* grows farthest up the slopes, succeeded in turn by Norway spruce, *Picea excelsa,* and a sparse growth of Scots pine. In valleys which were submerged in glacial lakes that have been drained since the ice melted back, large areas of fine fertile sand or loam were deposited and have made possible grazing and even considerable tillage at elevations from 2,000 to 2,500 ft. The moraine and peat moss belt, the middle belt of northern Sweden, lies at an elevation of from 600 to 1,500 ft. above sea level. The belt is a relatively level area cut by river valleys into plains many miles in extent, intersected by numerous stony moraines, and characterized by extensive development of marshes and peat bogs which occupy from 15 to 30 per cent of the belt. It is the moraine and peat moss belt that supports the greater part of the timber for which Sweden is famous. The forest, chiefly of Scots pine and Norway spruce, extends for more than 600 mi. along the belt, with a width that varies from 100 to more than 150 mi., a monotonous landscape broken by a few productive farms on southward-facing slopes. The farms are most numerous toward the southern part of the belt, which has a milder climate. It is in this belt that the chief ore deposits and mining enterprises of Sweden are found. The marine sand and clay belt, the easternmost belt of northern Sweden, is a region of broad coastal plains formed when the sea level

stood from 450 to 600 ft. higher than now. The marine deposits penetrate from 50 to 100 mi. into the interior. As the land rose after the ice melted, the many rivers that flow across the belt cut deep gorges into the deposits to form canyons and chasms which constitute some of the most scenic features of Sweden's picturesque terrain. The whole region of northern Sweden is sparsely populated. Forestry is the chief industry and yields the larger part of the income, although mining, particularly of iron ore, forms an important feature of the economy. Farming plays a minor role. The great water-power potentialities of the region are rapidly being developed. The serious problem of transportation gradually is being solved.

*Southern Sweden.* The three subregions of southern Sweden—the central lowlands, the Småland highlands, and the plains of Skåne—are the areas of densest population. Here also is the greatest concentration of manufacturing and farming; forestry and mining likewise play appreciable roles in the economy of the region. The central lowlands are marked by great level areas of marine deposits. They are generally arable and fertile, with soils which are readily adapted to mechanized farming. The lowlands are interior extensions of the marine sand and clay belt of northern Sweden, and in turn are connected with similar coastal districts in the Småland highlands and the plains of Skåne. The forests are luxuriant throughout the area, but much of the land is devoted to farming and grazing. The Småland highlands include all the area of southern Sweden that lies above the extent of marine deposits. It so closely resembles the moraine and peat moss belt of northern Sweden in terrain and vegetation that it may properly be considered an outlier of that continental plateau. Though the rivers are not so large and deep, the countryside is largely mantled with a coarse, sandy, and gravelly till, little adapted to farming but favorable to growth of pine and spruce. There are great areas of peat bogs; only the more temperate climate makes the Småland highlands suitable for habitation. The Skåne plains, southernmost and most gracious of all the Swedish regions and provinces, constitute the chief agricultural section of the country. The soils, derived from marine deposits interspersed with glacial till, are highly fertile, easily tilled, and productive of high yields of many crops. The plains are subdivided into a number of minor areas by rocky ridges, remnants of primitive rock that intersect the province chiefly from northwest to southeast. Forests of maple, beech, oak, ash, and other hardwoods once grew luxuriantly over the plain, but most have been cleared to make way for highly profitable agricultural activities.

**Climate.** The climate of Sweden is milder, sunnier, and drier than that of most countries in northwestern Europe, particularly in winter. This is because of the beneficent effect of the Gulf Drift, which washes the western coast of the Scandinavian Peninsula, and the warming and drying of the air that is borne by the prevailing westerly winds up the windward side of the Kjölen in Norway and then poured down from the heights upon the lower regions of Sweden. The great latitudinal extent of Sweden makes its northern region considerably colder, shortens its growing season, increases disparity between length of day and night, and otherwise increases differences in climatic elements from north to south.

Although 15 per cent of Sweden lies north of the Arctic Circle and all of it is north of the fifty-fifth parallel, the south-southwesterly winds that prevail over northwestern Europe, especially during the winter, give Sweden a climate that promotes forest growth, makes agriculture more productive than in similar latitudes elsewhere, and enables the

people to live comfortably. Summers are short and winters are long in all of Sweden; in summer the days are long, the nights short, and in winter the reverse holds true. In June the average daily sunshine for the country is 50 per cent; in December only 26 per cent; thus the heating effect of the sun in summer is unimpaired, while in winter radiation is considerably reduced by the widespread cloud cover. Summers are consequently warmer than they would otherwise be, and winters milder. At Lund, in southern Sweden, winter is 72 days long; spring, 72 days; summer, 142 days; and autumn, 79 days. At Karesuando, in northern Lappland, winter is 215 days long; spring, 43 days; summer, 57 days; and autumn, 50 days.

Generally speaking, the climate of Sweden lies about midway between continental and marine types, the northern part of the country being more continental and the southern part more marine. At Lund the mean monthly temperature varies from 33.5° F. in January to 61.5° F. in July, a range of 28 degrees, and the mean annual temperature is 45° F. At Karesuando the mean monthly temperature varies from 5.7° F. in January to 53.5° F. in July, a range of 47.8 degrees, and the mean annual temperature is near 27° F. Snow falls everywhere in Sweden every year, but the snow cover remains on the ground in open country only 47 days in Skåne, while it lasts 170 to 190 days in Karesuando. In the severe winter of 1880-1881 snow covered the ground in Stockholm for 166 days, but in the mild winter of 1881-1882 it remained only 33 days. Ice cover on the lakes averages about 115 days in southern Sweden, 150 days in central Sweden, and 200 days or more in northern Sweden. The Gulf of Bothnia is generally covered with ice every year. Ice begins to form along

shore about the middle of November and begins to break up in the latter part of May. Fogs are fairly common in the Gulf of Bothnia and the northern Baltic.

The average annual rainfall varies from 18 in. on the island of Gotland in the Baltic and the northernmost sections, to 28 in. on the western coast of southern Sweden. The average for the whole of Sweden is about 21 in.; but 18 to 20 in. for the northern provinces, 22 in. for central Sweden, and a little over 23 in. for southern Sweden, is remarkable uniformity for so large an area with so diversified a terrain. The maximum precipitation comes in late summer, with a secondary maximum in October for some places, which in exceptional cases may be the primary maximum. The minimum comes in February, March, or April. Summer and autumn rainfall distinguish all of Sweden, and drought conditions prevail from the latter part of winter to the early part of autumn, which frequently is a hazard for agriculture. Storms are relatively frequent on the west coast, averaging twenty a year, while on the east coast they vary from two to eight along the Gulf of Bothnia.

**Soils.** The soils of Sweden are chiefly forest and peat soils, most of them with varying degrees of acidity except where calcareous parent materials may affect them. Podsols, with light gray leached upper horizon, and gray to brown forest soils partly podsolized, are the dominant classes in Sweden. Only in the central lowland and on the plains of Skåne are the soils well suited for crop growing.

**Rivers and Lakes.** The many rivers of Sweden, none very large, form a close lattice pattern obvious on even a large map of the country and play an important role in its economy. More than 45 rivers drain basins of 600 sq. mi. or more. They may be divided into two major groups: those which include the great mountain lakes and valleys, from Dalälven northward to Tornälven and across Norrland from Kjölen to the Gulf of Bothnia, and those which form part of the great lake-river systems of Mälaren, Norrström, Vättern, Motalaström, Vänern, and Gotaälven. The principal rivers of Sweden are important as sources of power, for transport of timber, and for recreation, but because they are so swift and turbulent in most of their courses, they cannot be extensively used for boating. The largest lakes of Sweden are those of the Swedish lowland: Vänern, 2,141 sq. mi. in extent; Vättern, 733 sq. mi.; Mälaren, 440 sq. mi.; and Hjälmaren, 185 sq. mi. They are all navigable and much used for transportation. The numerous mountain lakes are so-called finger-lakes, long and narrow. They are used considerably for timber transport, but little for navigation or other purposes. They lie at nearly the same elevation, the difference being less than 300 ft. between the lowest and highest. A lake of exceptional beauty and popular regard is Siljan in Dalarna, the historical and political heart of Sweden.

**Canals.** The famous canal of Sweden is the Göta, which connects Stockholm with Göteborg on the southwestern coast; Jönköping, at the southern end of Vättern; and numerous other cities of the central lowland. Both Vänern and Vättern, the two largest lakes of Sweden, form part of the Göta Canal system. Other major canals of Sweden are the Hjälmaren; the Strömsholm; the Trollhätte, which bypasses all the falls on the lower Götaälven; and the Södertälje, one of the oldest still in use.

**Forests.** The forests of Sweden are its largest and most assured source of income. Nearly all of northern Sweden, most of the Småland highlands, large parts of the central lowland, and even rugged ridges about the plains of Skåne are forested. Conifers—spruce, fir, and pine—form the major part of the forest, but in southern Sweden hardwoods are now sparingly mixed among the conifers, where once they grew over large areas. More than 37 per cent of the forest lands belong to the nation, 2 per cent to towns or other political divisions, and the rest to private individuals.

**Flora.** The flora may be classified into five major regions: (1) the Alpine, which comprises the northernmost and highest part of the country, and consists chiefly of alpine heath, all dwarfed or small species; (2) the birch forest, next below the bare Alpine zone, characterized by the Alpine birch, *Betula odorata,* a subalpine tree forming low, thin forests of highly irregular extent and including in places quaking aspen, *Populus tremula,* and rowan, *Sorbus aucuparia*; (3) the northern region of coniferous forest, composed chiefly of Scots pine, *Pinus sylvestris,* and common spruce, *Picea excelsa,* which occupy the greater part of Sweden's land surface and determine the general character of the landscape; (4) the southern region of coniferous forest, which has been largely felled to make way for farm land but, where it persists, is strongly mixed with trees of oak flora—oak, ash, elm, linden, maple, and others; and (5) the beech forest region, now largely in cultivation after clearing of the forest, but where stands still exist is well mixed with oak, alder, and other deciduous trees, and in places with Scots pine. A luxuriant lake vegetation characterizes the many bodies of water; along the coast a rich halophytic or salt-tolerant flora thrives, and bogs and moors support a goodly stand of acid-tolerant plants. The vegetation of Sweden remains fresh and green throughout the growing period.

**Fauna.** Sweden has a richly diversified fauna both because of its length from north to south and its varied terrain. Each of the great vegetation regions supports its own distinctive species of insects, birds, rodents, fish, and carnivores. Its largest mammals are elk, red deer, reindeer, bear, lynx, and wolf; smaller mammals include the lemming, wolverine, pine marten, weasel, badger, hedgehog, squirrel, shrew, and bat. The birds are particularly numerous and varied. There are relatively few reptiles, frogs, or toads. The lakes, rivers, and coastal waters are abundantly supplied with fish and some shellfish. A distinctive fish of the Baltic and the Gulf of Bothnia is the strömming, *Clupea harengus,* a species of herring. In inland waters the native crayfish is abundant and considered a delicacy. W. E. E.

## ETHNOLOGY AND POPULATION

**Population.** The total population of Sweden in the 1950 census was 7,046,920; in 1945 there were 10,193 Lapps. In 1950 there were over 100,000 foreigners in residence. According to the 1950 census figures, the largest city in Sweden was Stockholm, the capital, with 745,936. Only two other cities exceeded 100,000; these were Göteborg, with 353,991, and Malmö, with 192,498. More than 50 per cent of the population was rural.

**Religion.** Most Swedes belong to the Lutheran Church, which receives state support. Other leading religious groups are: Baptists, 56,898; Methodists, 11,450; Roman Catholics, 4,763 (with a vicar apostolic at Stockholm); and Jews, 6,653. Some civil disabilities are attached to members of non-Lutheran churches.

**Economic Pursuits.** In 1945, 60.4 per cent (2,509,635) of the people were dependent upon industry for a livelihood. Agriculture absorbed 1,867,190 persons, and the professions the remainder.

**Language.** The official language is Swedish and the formal dialect is that of Stockholm, but several variants are used in the kingdom. Finnish is spoken in the northern provinces.

## GOVERNMENT AND POLITICS

**Central Government.** Sweden is a constitutional monarchy with Gustavus VI (1882- ) as king. The king appoints some officers and is commander in chief of the armed forces. The cabinet exercises the other executive functions. The legislative branch is the *Riksdag,* which is composed of 150 members in the First Chamber, or upper house, and 230 members in the Second Chamber, or lower house. The members of the First Chamber are elected by provincial legislatures, or *Landstings,* and town councilors; persons over the age of 35, eligible to vote in municipal elections, may be elected. The members of the Second Chamber are elected by universal suffrage, and persons over the age of 25 are eligible for membership. The kingdom is divided into four high district courts, 186 district courts, 71 city, and 115 country superior courts. The king appoints a chancellor (Justitie-Kansler), who is administrative head of the legal system. An attorney general (Justitie-Ombudsman) is elected by the Riksdag. Trial by jury is only for cases involving liberty of the press; other cases are tried by judges.

**Civil Rights.** All persons, male and female, over the age of 23 have the right of suffrage, and only those barred by law because of criminal or religious reasons are prevented from voting. Complete freedom of speech, press, and assemblage is guaranteed by the constitution, and right of appeal to the courts is permitted for redress of any infringement.

**Political Parties.** The strength of the political parties in the Second Chamber in 1952 was: 108 Social Democrats, 59 Liberals (People's Party), 28 from the Farmers' (Peasants') Party, 30 Conservatives, and 5 Communists. The First Chamber had 81 Social Democrats, 23 Conservatives, 23 from the Farmer's Party, 20 from the Liberal, and 3 Communists. The majority party, the Social Democratic, has been in power since 1932, except for a brief interruption in 1936, and its political philosophy is Marxist. Per Albin Hansson, who died on Oct. 6, 1946, was its leader for many years. The Conservatives represent the large landowners and industrialists. The Farmer's Party is composed of small landowners, consistently conservative and desiring protection of home agriculture from foreign competition. The Liberal or People's Party is midway between the Social Democrats and Conservatives in political ideology. No great political conflict has arisen in the past decade; the coalition cabinet of World War II functioned well in spite of differences of opinion on domestic issues.

**Public Finance.** The estimated budget for 1951-1952 was (approximate figures in American dollars based on exchange value of the krona): receipts 6,406,395,000 kr. ($1,281,279,000); expenditures, 5,751,026,000 kr. ($1,150,205,000).

In 1950 the public debt was 12,421,000,000 kr. ($2,484,200,000). The unit of currency is the Swedish krona of 100 öre and is valued on the exchange at 19.4 cents and officially at 5.14 kroner to the dollar. The Sveriges Riksbank is the official state bank of Sweden; its directors are elected by the Riksdag for three-year terms and its president is appointed by the king.

**Government Enterprises.** The Swedish government owns most of the railroads, telegraph and telephone lines, extensive forest lands (more than 10,000,000 acres), the tobacco monopoly and control of liquor, and the Swedish

EWING GALLOWAY

*Molten steel being poured into ingot molds at one of the foundries in Fagersta, the center of Sweden's pig iron industry*

Broadcasting Company. Subsidies are granted to farmers and to co-operatives, to the Swedish Inter-Continental Air Lines, to A/B Aerotransport Company, and to a private mining corporation, the Kiruna-Luossavara Bolaget (KLB), which is state owned. The Royal Board of Waterfalls controls over 40 per cent of the production of hydroelectric power and plans for the production of more.

**Armed Forces.** The armed forces of Sweden were on a war footing throughout World War II. All males between 20 and 47 are subject to military service. In 1950 there were 19 infantry, 3 cavalry, 4 tank, and 9 artillery units; 3 antiaircraft regiments and 4 antiaircraft defense corps; and 18 air force squadrons. The navy had 4 cruisers, 6 coastal defense ships, 21 destroyers, 6 torpedo boats, 42 mine sweepers, 28 submarines, and 2 mine layers; 2 cruisers and 2 destroyers were being built. Sweden is divided into six naval districts, with stations at Karlskrona, Stockholm, and Göteborg. Naval personnel totaled approximately 10,000 officers and men. The Royal Coast Artillery maintains defense forts at Vaxholm (Stockholm), Karlskrona, Alvsborg, Gotland, and Hemsö.

*An electrical equipment manufacturing plant at Västerås*

EWING GALLOWAY

## ECONOMIC RESOURCES AND ACTIVITIES

**Agriculture.** Agricultural production is insufficient for domestic needs, and rationing was introduced during World War II. In 1948 there were 9,215,662 acres under cultivation; 55,219,389 acres were in forest land. Hay, of which 4,297,968 metric tons were produced in 1948, is the leading crop, followed by potatoes (2,276,511 metric tons), fodder (2,080,249), and sugar beets (1,808,200); other crops, raised in lesser quantities, were oats, wheat, mixed grains, rye, and corn. In 1948 the livestock census showed 14,166,000 poultry, 2,622,000 cattle, 1,194,000 pigs, 497,000 horses, and 349,000 sheep.

**Mining.** Mining, for which Sweden is mainly noted, is concentrated in the north and is concerned chiefly with production of iron ore. In 1950, 13,611,000 metric tons of ore were produced, followed by pyrites (406,809 metric tons), coal (309,296), gold (72,300), zinc (62,094), copper (61,264), silver-lead (29,973), and manganese (11,847). The quarries provide paving blocks, cement materials, and building stone. The value of all mineral production in 1949 was $344,977,000.

**Manufacturing.** The industries of Sweden are geographically decentralized with mining and its byproducts in the north; sawmills and wood products along the Gulf of Bothnia; machinery, ball bearings, electrical machinery, telephone supplies, and motors in central Sweden, and the porcelain and glass factories of Orrefors, Kosta, and Gustafsberg in the south. The manufacture of iron and steel products far outweighs in value any other Swedish manufactures. Of the total production value of $3,205,985,000 in 1946, $1,043,925,000 was for iron and steel. Next in value were foodstuffs and spirits ($719,337,000) and paper products ($362,418,000).

**Fisheries.** The fisheries, located chiefly at Göteborg, are not extensive; in 1947 the total tonnage of fish exports was 17,591, with a value of $3,530,000. Most of the fishing is done in the North Sea, but some catches are made in the Baltic Sea.

**Commerce.** The commerce of Sweden is mainly with Great Britain, the United States, and the Soviet Union; before World War II Sweden's main customer was Germany. Imports and exports in 1950 and their values were as follows: imports, $1,220,533,000; exports, $1,141,956,000.

**Banking.** The banking system is entirely under the control of the state, and the Riksbank is the only official bank. However, there are 25 commercial banks with deposits of $1,559,000,000 and loans of $1,274,000,000. The Post Office Savings Bank also offers service to 3,591,993 depositors, who have $303,100,000 on deposit. There is very little foreign banking service in Sweden, but state bonds are held abroad in considerable quantities.

**Transportation and Communications.** Through the merchant service, composed of 2,195 ships and 2,088,579 gross tons in 1949, connections are maintained with all foreign countries. The Swedish-American Line, Svea Line, Johnson Line, Swedish Lloyd, Swedish Orient, Transatlantic,

and Transpacific provide regular steamship service between Sweden and virtually all parts of the world. Within Sweden there are 55,500 mi. of roads and 10,340 mi. of railroads; telegraph lines total 7,681 mi. and telephone wires 1,317,052 mi. The Göta Canal connects the Gulf of Bothnia with Göteborg. The Swedish Inter-Continental Air Line and Scandinavian Airlines System connects Stockholm and other Scandinavian cities with the United States; the A/B Aerotransport Company has regular flights to European capitals.

**Labor Movements and Conditions.** The labor movement, begun in the late nineteenth century and fostered by the Social Democratic Party, has had great political weight. Hjalmar Branting, long the leader of the Social Democrats, was one of the early founders of the trade union movement. The Swedish Trade Union Federation and T.C.U. have together over a million and a half members, representing over 30 per cent of the entire population over fifteen years of age. During 1950 there were 23 strikes or lockouts affecting 2,436 workers, of which all but three disputes were settled by compromise. Laws providing accident insurance, hospitalization, old-age pensions, unemployment insurance, and factory regulation offer the Swedish worker a standard of living of which he is proud, and industrialists aspire to maintain that standard.

## SOCIAL AND CULTURAL ACTIVITIES

**Standard of Living.** *Health.* The Swedish people are as healthy as the people of any state in Europe. Social medicine provides adequate safeguards against incidence of disease, and state hospitals and clinics furnish medical attention free of charge. State institutions provide treatment for tuberculosis and other respiratory diseases.

*Housing, Fuel, and Clothing.* Wartime conditions meant little construction of homes, and housing is inadequate, but co-operative and state-aided housing units are being expanded. Refugees from other countries, totaling 193,000 in 1945, complicated the housing problem. The problem of fuel has always distressed the Swedish urban housewife, but never quite so seriously as during the war. Coal imports supply almost 70 per cent of fuel demands, and the war shortage was filled by peat, firewood, briquettes, and low-grade coal. There was no motor fuel for civilian automobiles unless they ran on producer gas (wood gas); and shale oil was for military purposes only. Hot water was rationed in most of the hotels and apartment houses, and restrictions were not withdrawn until February 1947. Raw materials for clothing have always been imported, and World War II forced the manufacture of various substitutes. Shoes were made of wood and paper; fabrics of rayon and cellulose. The government subsidized new industries to produce cotton and woolen materials.

*Family Life.* The Swedish family has not changed with the years; an increasing birth rate indicates that higher costs of living have had little effect on it. The divorce rate of 8.43 per cent is not high. Since Sweden's industrialization and urbanization have not been excessively rapid, the contour of the family has not been altered appreciably. The government has built housing units and gardening plots and has given every encouragement to larger families.

*Holidays and Recreation.* Every holiday is a gala occasion, and Christmas is traditionally a great festive celebration with visits to friends and relatives. Swedes are famous for their culinary art. They are also conscious of the need for physical fitness; since the days of Pehr Henrik Ling, Sweden has been an outstanding center of physical education. The Gymnastics Association acts as a central statistical, propaganda, and co-ordinating agency. Skiing is a national sport, and a walking association encourages hiking. Cycling became popular during the war, when it was no longer possible to use an automobile. A steady improvement of the health of the Swedish people has been noted.

**Education.** The education of the Swedish people has always been extensive; school attendance between the ages of 7 and 14 is compulsory. Illiteracy is less than 1 per cent. The elementary schools had 506,505 pupils in 1947; the secondary schools, 68,453, and the people's high schools, 7,346. Eleven elementary and two higher technical schools offer professional training. Several institutions are for the blind, deaf, and mute, and other special classes. In Stockholm facilities for higher education include a semipublic university which co-operates with eight independent professional schools in the city. The universities at Uppsala (1477) and at Lund (1666) are both internationally recognized for their superior training. A fourth university is among the educational institutions at Göteborg. Agricultural institutes are located at Uppsala and at Akarp.

**Art.** Sweden's art has never been famous, except that which is functional, but its National Museum is known for its treasures. The National Association for Promotion of Fine Arts, the Swedish Arts Association, and the College of Arts in the Royal Academy have inspired the Swedish people to a sense of beauty. Swedish art is practical and real. Swedish glass from Orrefors in Småland has been famous for two decades; intricate weaving by peasant women has beautified homes and clothing; Swedish furniture has gained a high repute. A few modern artists have revealed the innate sense of beauty of the Swedes: Carl Larsson's glimpses of Swedish life; Prince Eugen's more elegant fashions; and Anders Zorn's Dalarna scenes.

**Drama, Music, and Literature.** The Swedish theatre also reveals the artistic impulses of the Swedish people. Both the Royal Dramatic Theatre, with Karl Ragnar Gierow, Per Lagerkvist, and Rune Lindström as its most famous playwrights, and the Swedish film industry are internationally known. In music, performance is preferable to composition. The Swedes have never produced a famed composer, but the Royal Opera and Academy of Music provide stimulus for enterprising artists. All peasant festivals are accompanied by singing and dancing; choral groups, singing clubs, and folk music are characteristic of Sweden. The modern literature of Sweden is not extensively known, although many countries are familiar with the writings of Selma Lagerlöf and Verner von Heidenstam. Eyvind Johnson and Vilhelm Moberg are among the foremost contemporary authors.

## HISTORY

The origins of Scandinavian man are not definitely known, but it is supposed that human life existed on the Scandinavian Peninsula as early as 12,000 B.C. Artifacts indicate a relatively high degree of civilization during the Paleolithic and Neolithic periods, and the Bronze Age showed signs of intercommunication with other European countries. The Roman Empire had trade relations with Scandinavia, but it was not until the eighth century that Scandinavia figured importantly in the history of Europe.

**Viking Period.** The Viking expeditions in which Swedes participated were mainly in the eastern Baltic. It was a Danish jarl or chieftain, Rurik, who about A.D. 862 established himself in the Russian city of Novgorod with the aid of Swedes who also participated in the attacks on Constantinople. From Novgorod, Rurik and his descendants

pushed southward and established themselves in Kiyev. Gradually these Swedish settlers mixed with the population and disappeared. Other Swedish colonists settled in the eastern Baltic littoral and opened trade with Russia, substituting the less adventurous role of merchant for that of a Viking. Within Sweden the Viking period brought a more energetic development of law, government, and society. In the ninth century Anschar (Ansgar) brought Christianity, and in 1008 Olaf Shötkonung accepted it and established a new bishopric at Skara. Missionaries followed and Sweden became Christian, although paganism remained for some time. Political unity was hard won; prominent families led the movement, with Birger of Bjälbo (Folkung dynasty) the outstanding political leader. Under his dominance Sweden resisted economic subordination to the German merchants and extended its influence in the eastern Baltic. A period of decline followed, broken only by the reign of Magnus Ericsson (1319-1356, 1359-1362), which was filled with his conflicts with Waldemar IV Atterdag of Denmark and Albert of Mecklenburg. Albert ousted Magnus and later made himself king. The feeble efforts of their leaders to maintain liberty forced the Swedes to agree to a marriage alliance with Denmark; the marriage of Haakon VI to Danish Princess Margaret in 1363 led to the union of Sweden, Norway, and Denmark in 1397.

**Union of Kalmar.** At the Diet of Kalmar in 1397, some years after the death of Haakon, Margaret persuaded the Estates to accept as king her grand-nephew, Eric of Pomerania, and the Union of Kalmar began. Sweden proved an unwilling partner in it, for revolts and friction constantly forced Danish intervention. Margaret and Eric were both distrustful of the Swedish nobility, and Danes received the chief offices. The traditional home of Swedish liberties, Dalarna, under Engelbrekt Engelbrektsson, was the first to rebel against Danish overlordship. Although Engelbrekt's leadership lasted only from 1434 to 1436, he created a sense of national unity; Karl Knutsson, who had been associated with Engelbrekt, assumed direction and in 1448 was elected king of Sweden as Charles VIII. One abortive attempt by Christian I to re-establish Danish control in Sweden failed, but in 1520 Christian II succeeded. The unfortunate celebration in 1521 of the execution of the leaders of the Swedish rebellion was fatal to the union. Upon receipt of the news, Gustavus Ericsson aroused his countrymen against the Danes. A simultaneous revolt in Denmark against Christian II assisted Gustavus in his fight, and at Strängnäs in June 1523 he was crowned king of Sweden as Gustavus I Vasa.

**Vasa Period.** The immediate problems facing Gustavus were formidable. Recognition by other states was slow; Denmark opposed the new regime; the country was devastated and divided because Gustavus' chief support had come from the peasants and not the nobility. Loans from Lübeck had given that city a strangle hold upon the economic life of Sweden which Gustavus wanted to end. Several revolts were successfully met by 1530, and trade and domestic peace soon provided both cash and unity. A religious revolt against Catholicism, begun by Olaus and Laurentius Petri in 1525, gave Gustavus an opportunity to seize church lands, and the Swedes had an independent church. The successors of Gustavus were not of his mettle. His son Eric, who ruled from 1560 to 1568, was insane, and Eric's brother John led a revolt which deposed him. An unstable and unscrupulous spendthrift, John mismanaged the kingdom and proposed a return to Catholicism. His death in 1592 brought his son, Sigismund of Poland, to the throne, and he, as an ardent Catholic, drove the Swedes to rebellion. In 1604 Charles IX, the third son of Gustavus Vasa, was elected king of Sweden. Though he lived but a short time, Charles restored financial stability, increased Sweden's possessions abroad, and built a strong monarchy for his son, Gustavus II.

EWING GALLOWAY

*Gustavus Adolphus.* The reign of Gustavus II, known as Gustavus Adolphus, was filled with incessant wars. It was fortunate for Sweden that in 1612 he appointed one of Sweden's greatest statesmen, Count Axel Oxenstierna, as chancellor. The chancellor ruled Sweden, managed the finances, and handled diplomacy while Gustavus pursued his military ambitions. Wars with Denmark and Russia were successfully concluded. A war with Poland from 1621 to 1629, was ended to permit Gustavus' intervention in the Thirty Years' War in Germany. In the same decade reforms took place at home, among them the departmental organization of government, the foundation of trading companies,

the proposals for colonial settlements in America, and the development of Swedish mines. The military fame of Gustavus in Germany rested on his superior tactics and the national character of his army, as opposed to the polygot nature of the Imperial forces. The victories at Leipzig (1631) and Lützen (1632) made Sweden a world power for a time. The death of Gustavus at Lützen did not materially affect the outcome of the war. Count Oxenstierna carried the burden of government and was chief minister for Sweden's young queen, Christina, from 1644 to 1654. The victories won by Swedish forces in Pomerania and at Leipzig saved the Swedish empire in Germany, and Lennart Torstensson, Gustavus' chief commander, forced Denmark to terms in 1644-1645. The treaties of Westphalia in 1648 and Copenhagen in 1660 marked the zenith of Swedish power in Europe.

CULVER SERVICE

*Queen Christina.* The reforms begun in the reign of Gustavus were continued by Oxenstierna; Swedish colonies were solidly founded; Sweden's wealth was increased and communications were improved. The reign of Christina, also an era of cultural renaissance, was terminated by the Queen's decision to adopt Catholicism. Unable to reign in Lutheran Sweden as a convert to the Church of Rome, Christina in 1654 announced her abdication, and on June 6 of that year gave up her throne in favor of her cousin. Her public entrance into the Church was made at Innsbruck in 1655.

**Sweden's Struggle for an Empire.** *Charles X Gustavus.* With the abdication of Christina the direct descendants of Gustavus Vasa ceased to rule. Charles X Gustavus, nephew of Gustavus Adolphus, began the *reduktions* whereby the crown regained thousands of acres of land and millions of dollars worth of property. The administration of Eric Oxenstierna, son of the famous chancellor, was devoted to economic reconstruction, necessary after the lavish expenditures of Christina and the heavy expenses of the Thirty Years' War. Sweden gained Livonia through an undeclared and unwarranted attack on Poland in 1656, although Charles extricated himself only through Denmark's mistake of declaring war on Sweden. The king withdrew his troops from Poland and crossed Germany into southern Jutland. An attack on the Danes ordinarily required a navy, but an unprecedented cold winter froze the waters between the islands and offered a chance to cross to Sjælland. Danish surprise at the daring of the Swedes was reflected in their unpreparedness, and Charles forced the Danish army to surrender. The ensuing Treaty of Roskilde in 1658 was the most notable victory that Sweden had won over Denmark. Now for the first time Sweden was free to undertake trade with western Europe through its "door to the west" at Göteborg.

*Charles XI.* The regency which ruled Sweden during the minority of Charles XI frittered away both the advantages and money which had been won. Swedish participation in Louis XIV's Dutch War of 1672-1679 was nearly disastrous. A Danish invasion of the southern provinces and Frederick William's invasion of Pomerania would have cost Sweden heavily if it had not been for the intervention of Louis XIV. The country was economically exhausted, and it was necessary for Charles XI to continue his father's policy of the *reduktions.* In the Riksdag of 1680 these were approved, but more importantly the members voted absolute powers to the king. The army was rebuilt on the grand scale of Gustavus Adolphus.

*Charles XII.* The reign of Charles XII, who became king in 1697 at the age of 15, marked the end of Sweden as an important European power. Denmark, together with Prussia, Poland, and Russia, plotted against Swedish domination of the Baltic, and in 1700 the attack was launched. Charles countered with an immediate attack on Denmark, and in August 1700 he forced it to sign the Treaty of Travendal. He then moved eastward to relieve Narva, which was besieged by the Russian army. There in November Charles

won his first victory over Russia, and from 1702 to 1707 he fought in Livonia and Poland against the Polish king, Augustus II. The latter was forced to sign the Convention of Altranstädt in September 1707, recognizing Stanislas Leszczyáski as king of Poland.

In 1707 Charles invaded Russia, although his officers had advised strongly against such a daring venture. The invasion progressed nicely until the scorched earth tactics of

Peter the Great forced Charles to turn south to winter. Orders were given to General Adam Levenhaupt to bring reinforcements, and negotiations with Mazepa, commander of the Cossacks, were begun. Both arrived in Charles's camp without their promised supplies or men. When Peter learned of the plight of the Swedes, he turned to fight them, and at the Battle of Poltava, June 28, 1709, the whole Swedish army of nearly 18,000 men was captured. Charles fled to Turkey and spent five fruitless years in exile trying to persuade the Turks to attack Russia. In 1714 he was almost forcibly ejected from Turkish territory and returned to Stralsund, which he defended against the newly formed northern alliance of 1714-1716. Shortly before the city's fall in December 1715, Charles left and returned to Sweden. By 1715 Peter the Great had taken the Baltic provinces, had nearly completed St. Petersburg, and had several times invaded Finland. Prussia was in control of the Oder River and most of Swedish Pomerania. Denmark had sold Bremen and Werden to George I of England. In 1716 Charles faced an invasion of Sweden by Denmark and Russia, which did not materialize, and himself invaded Norway, where he was killed at Fredrikstad, Nov. 30, 1718, while directing the siege. His death ended Sweden's fight for an empire; only Finland and western Pomerania remained of the once extensive Swedish possessions.

**Eighteenth Century.** *Cultural Progress.* The Riksdag dominated Swedish affairs during the reigns of Ulrika Eleonora, Frederick I, and Adolphus Frederick. The enlightenment of the eighteenth century brought a great renaissance which produced the Academy of Sciences, the Academy of Letters, the Swedish Linguistic Society, the Academy of Arts, the Royal Swedish Opera, and the Royal Academy of Music. Olof von Dalin, as a poet and historian; Sven Lagerbring, as a critical historian; Karl Mikael Bellmann and Johan Henrik Kellgren as poets and critics; and Eric Benzelius, as the famed librarian at the University of Uppsala, were representative of this cultural progress. Scientific progress was reflected in the work of Carl von Linné (Linnaeus) in botany, T. O. Bergman and Karl Wilhelm Scheele in chemistry, Anders Celsius in astronomy, and Emanuel Swedenborg in geology, medicine, and religion.

*Gustavus III.* Gustavus III, who ruled from 1771 to 1792, is and is regarded as Sweden's enlightened despot, resolved to restore the powers of the monarchy. The revolution of 1772, managed by the king himself, substituted the monarchy for the Riksdag as the authority in Sweden. In the latter part of his reign Gustavus embarked on an ill-advised project to regain Sweden's possessions. The war with Russia in 1788-1790 might have proved disastrous for the Swedes after Denmark invaded their territory, but the French Revolution, the partition of Poland, and Swedish victories in Finland caused Russia to sign a peace, and Sweden escaped unscathed. The anticlimax was the assassination of Gustavus by Johan Jakob Anckarström, one of his nobles, on Mar. 29, 1792.

*Gustavus IV Adolphus.* During the eight years of regency which followed, Sweden drifted. Gustavus IV Adolphus, crowned king in 1800, was a reactionary who proposed intervention in France. Because of his foolhardy policy, Sweden lost Pomerania in the German war of 1806-1807 and faced Russia alone in 1808 in Finland. Gustavus, by now demented, was deposed by a *coup d'état* in March 1809, and on Sept. 17, 1809, peace was made with Russia, Sweden losing Finland.

*Bernadotte.* Charles XIII, who had been regent from 1792 to 1800, ruled from 1809 to 1818. Since he was childless, it was necessary for the Riksdag to select an heir apparent. A French marshal, Bernadotte, was chosen as heir to Charles. In order to win Norway he reoriented Swedish foreign policy from France toward Russia and joined the coalition of

1813-1814 against Napoleon. Denmark ceded Norway to Sweden at Kiel, Jan. 14, 1814, and Bernadotte forced the Norwegians to recognize the act. The Eidsvold Constitution, framed by the Norwegians in 1814, was retained as the basic law, and Norway was permitted its own parliament.

**Nineteenth Century.** *Era of Peace.* The end of the Napoleonic era brought a peace to Scandinavia which lasted until 1940. Bernadotte, who in 1818 succeeded Charles XIII as king and took the name Charles XIV John, was opposed to liberal movements and personally felt responsible for the preservation of the union. Toward the latter part of his life his increasing conservatism and irritating habits lost him

## RULERS OF SWEDEN

| Dates of Reign | | Name | Succession | Born | Died |
|---|---|---|---|---|---|
| 980 | 995 | Eric the Victorious | King at Uppsala | c. 964 | 995 |
| 995 | 1022 | Olaf Shötkonung | Son of Eric; first king of all Sweden | ? | 1022 |
| 1022 | c. 1050 | Amund (Anund) | Son of Olaf | ? | c. 1050 |
| c. 1050 | 1060 | Emund the Aged | Half brother of Amund | ? | 1060 |

some public sympathy. During his reign, however, Sweden improved its transportation system, accepted the Industrial Revolution, developed its natural resources, and became a leading country in the production of fine steel. Culturally, too, the early nineteenth century was a great age for Sweden. Pehr Henrik Ling made it a pioneer in physical education. Erik Gustaf Geijer and Esaias Tegnér studied its past and colorfully portrayed it for their generation. J. J. Berzelius in chemistry, Anders Retzius in anatomy, and the Caroline Medical Institute made it a pioneer in science.

*Oscar I.* Oscar I's accession in 1844, though eagerly anticipated, proved a bitter disappointment to liberals desiring political reform. It was not until 1867, during Charles XV's reign, that new constitutional laws were written to answer the demands of the middle class and peasants. Lars Johan Hierta, the editor of the *Aftonbladet,* Johan Gabriel Richert, Louis de Geer, and others led the movement for political reform; novelist Fredrika Bremer stressed the importance of women's rights. Religious liberty was conferred; local government increased in power, and a modern banking system was introduced in the Stockholms Enskilda Bank. The Bessemer process proved a great boon to steel production, and the building of the Göta Canal and railroads furnished a modern transport system.

*Oscar II.* During Oscar II's reign, 1872-1907, growing industrialization and the rise of the Social Democratic Party under Karl H. Branting brought the passage of extensive social legislation and factory regulation acts. Co-operative societies, for which Sweden is noted, were begun. August Strindberg, Gustaf af Geijerstam, Verner von Heidenstam, and Selma Lagerlöf were world-famous in literature. In the scientific field the explorers Sven Hedin and N. A. E. Nordenskjöld and the archaeologist Oskar Montelius won international praise. Gustaf von Rosen, Nils Forsberg, Julius Kronberg, and Karl Gustaf Hellquist portrayed Sweden's past greatness in oils. Impressionism in the work of Ernst Josephson and Richard Bergh influenced a modern school of art. The major problem faced by Oscar II was the dissolution of the union of Norway and Sweden. The union had not been happy for either partner, and disputes continually arose. In 1905 the Norwegian Storting, or Parliament, formally passed a dissolution act, forcing Sweden to decide whether Norway should be permitted to "depart in peace." Oscar II was a proponent of that course, and at Karlstad, Sept. 23, 1905, an agreement was signed which gave Norway its freedom.

**Twentieth Century.** Sweden's problems changed little in the new century. Gustavus V, more commonly known as King Gustaf, who came to the throne in 1907, understood the role of a democratic monarch and endeared himself and his family to the Swedish people. The Social Democratic Party steadily gained in political influence, and the strike of 1909, which was almost fatal to the trade-union movement, only temporarily checked this advance. The discussions of military preparedness in 1914 stirred party animosities and was an issue of some significance.

During World War I Sweden remained neutral and insisted on the observance of her neutral rights. Nevertheless, some 300 Swedish ships were lost, rationing was introduced, and the people felt the impact of modern war for the first time. In 1918 the country assumed a benevolent attitude toward Finland and its revolution, but the question of possession of the Ahvenanmaa (Åland) Islands, decided by the League of Nations, nearly caused war between the two states. Postwar problems were like those of the rest of Europe; inflation, national debts, and security in foreign relations occupied the government's attention. The depression of the 1930's gave the Social Democratic Party a majority in the Riksdag, where it remained dominant, with a minor interruption, until 1950. Swedish industries, in the two decades between the wars, produced more than ever before, and a monopolistic tendency developed. The Swedish co-operatives, however, met this challenge and forged ahead. The Kooperativa Förbundet (KF), founded in 1899, with its 750,000 members, was outstanding. Consumer, wholesale, and manufacturing co-operatives were organized; in 1941 the KF had a capital of $23,000,000 and a wholesale business of $64,000,000. Moreover, the Nordisk Andelsförbund had formed a Scandinavian co-operative society with members in Norway, Denmark, Sweden, and Finland.

Sweden's foreign policy from 1920 to 1939 was pacific; it joined the League of Nations, the World Court, and other international organizations. In World War II Sweden again stated its desire to remain neutral, but the German invasions of Norway and Denmark and the threats of attack on Sweden necessitated preparedness measures. Armed forces were kept on an active basis, and several thousand persons were killed on patrol duty. Sweden's sympathies, not often openly expressed, were on the side of the Allies; Norway, Denmark, and other countries were aided through the Red Cross, many of their refugees were harbored, and other forms of relief were extended to them. After the war Sweden took its place in the United Nations, thus resuming its former peacetime role of international co-operation. Its sincere interest was shown through the millions of dollars in gifts and reconstruction credits granted to Denmark, Finland, and Norway. Export-import agreements were reached with Denmark and Norway, and other trade pacts were signed with the Soviet Union, France, Great Britain, and Poland. Sweden was invited to participate in the European Recovery Program in 1948 and aided materially, through its industrial production, Europe's advance in postwar reconstruction. In 1950 the country was able, for the first time since 1938-1939, to achieve a near balance in imports and exports and thus was well on the road to economic readjustment. Increasing political pressure from the Soviet Union on western Europe caused virtual abandonment of three trade agreements; the one with Poland was supposed to provide Sweden with coal essential for the steel industry. In 1948 discussion of a Scandinavian defense pact was strongly urged upon the northern countries, but Sweden continued its policy of neutrality, holding to the view that rearmament would hasten conflict between East and West and increase Soviet pressure on Finland. The same considerations caused the Swedish government to refuse adherence to the North Atlantic Pact which was signed in 1949 by Norway and Denmark. Subsequent negotiations in 1950 among the three Scandinavian countries attempted to reach a formula which would leave Denmark and Norway within the North Atlantic Pact and yet provide a joint defense system among the three countries. Sweden participated in all the activities of the United Nations, and a member of the royal family, Count Folke Bernadotte, was assassinated while serving the United Nations in Palestine. With the death of the popular Gustavus V in 1950 at the age of ninety-two, Sweden's longest reign came to an end. Under his son and successor, Gustavus VI (Gustaf Adolf), the Swedish people, both internationally and in domestic affairs, appeared entirely content to continue pursuing the middle way.

**SWEDENBORG, EMANUEL** [sve'dənbɔry] (1688-1772), Swedish scientist, philosopher, and theologian, whose

writings form the doctrinal basis of the Church of the New Jerusalem, or New Church, was born at Stockholm on Jan. 29, 1688. His father was a professor at Uppsala and Lutheran bishop of Skara. The family name was Svedberg, but when Swedenborg was ennobled in 1719 the "en" was added, corresponding to the German "von."

Swedenborg was trained at Uppsala and travelled widely in Europe. His earliest interests were scientific, and these interests led him into every branch of the physical sciences. His accomplishments in this field were considerable: his invention of a device for transporting boats overland was the immediate occasion of his elevation to the House of Nobles, where he became a leader, and his knowledge of mineralogy led to his appointment as assessor of the Royal Bureau of Mines in 1716, a position which he held for over thirty years. Swedenborg wrote many notable scientific volumes and published a periodical, *Daedalus hyperboreus,* devoted mainly to mechanics and invention. His works were collected and published by official order near the end of the nineteenth century.

In his theories of the principles of the universe and in the field of mechanics Swedenborg was far in advance of his time and anticipated many later discoveries; his nebular hypothesis antedated Kant and Laplace. He also devised a method of ascertaining longitude at sea by the stars, invented an ear trumpet for the deaf, set forth a molecular theory, began the science of crystallography, drew up plans for a machine gun, a submarine, and a flying machine, and even developed a theory of cosmic atoms.

In 1743, however, Swedenborg was turning his mind from the natural sciences to religion. At this time he began to experience a sort of illumination which, he felt, gave him an extraordinary and even a divine sense of spiritual perception. He reported that he plunged deep into mysticism, heard mysterious conversations, saw visions, received revelations, saw heaven and hell, and conversed directly with angels and even with God himself. He felt himself divinely commissioned to expound his revelations and perceptions and even suggested that his theological writings were dictated to him by God. In 1745 he published his Latin *Worship and Love of God* (English translation, 1801), and in 1749 he completed his vast Latin work in eight volumes, *Arcana coelestia* (English translation, 1783). These works were followed by a dozen other books of a theological nature, the best known being *Heaven and Hell,* first published in Latin in 1758 and in English in 1778, and *The Apocalypse Revealed* (Latin, 1766; English, 1791).

Swedenborg taught that God's divinely inspired revelation, or Word, was found in certain (but not all) books of the Bible. This Word, however, was not the commonly accepted sense of the written record, but in a more or less hidden spiritual meaning which Swedenborg felt it was his mission to reveal. There is accordingly a certain esoteric principle in his system of doctrine.

Swedenborg died on Mar. 29, 1772, while on a visit to London. He was buried in the Swedish Lutheran church there, but in 1908 the Swedish government transferred his remains with considerable honor and ceremony back to his native land and deposited them in the cathedral at Uppsala.

**SWEDENBORGIANS** [swidənbɔ′rjiəns], members of the Church of the New Jerusalem, or New Church, and followers of Emanuel Swedenborg (1688-1772), Swedish scientist and theologian.

Swedenborg's doctrinal system was complicated and complete, and it contained an esoteric element. He taught a correspondence or relationship between all things in the universe, including God, angels, man, and all earthly substances, by means of "discrete degrees," different from "continuous degrees" or the ordinary degree relationship, which involves the relationship of cause and effect.

Much Swedenborg teaching follows Protestant theology, though with divergencies. Its distinguishing characteristic is its view of the Word of God, the divine revelation plenarily dictated by God and inspired in every word. According to this view, the Word is found in the Old Testament in the Pentateuch, Joshua, Judges, Samuel, Kings, Psalms, and the prophets from Isaiah to Malachi, while in the New Testament it is in the four Gospels and Revelation only; the other biblical books are important for life and devotion but are not a part of the Word.

The Word of God, however, cannot be found in the Scriptures, Swedenborg believed, if they are interpreted like other writings in their ordinary sense. In addition to their literal meaning for men there is a spiritual meaning adapted to angels, and Swedenborg's revelations or perceptions were designed to disclose or provide the key to that spiritual sense. It is at this point that the esoteric principle enters.

Swedenborgian churches grew up in London in 1784 and were incorporated in 1821. A new church society was formed at Baltimore in 1792. The General Convention of the New Jerusalem in the United States of America was organized in 1817.

There are two Swedenborgian bodies in the United States. The General Convention had 52 congregations and nearly 4,621 members in 1947. The other body, called the General Church of the New Jerusalem, was formed in 1890 by the withdrawal of the Pennsylvania Association on the issue of strict adherence to the teachings of Swedenborg as an inspired revelation. Its headquarters are at Bryn Athyn, Pa., and it reported 10 churches with approximately 1,496 members in 1950.

E. T. C.

**SWEDISH,** the language spoken by about 6,500,000 persons in Sweden and by the coastal population of Österbotten (Vaasa) and Nyland (Uusimaa) in Finland; it is also spoken on most of the islands of the Baltic, including some off the coast of Estonia. Swedish was the principal tongue of 342,916 persons in Finland in 1930, and furthermore it is spoken as a second language by all cultivated Finns. Altogether Swedish is spoken by about half of the whole Nordic group.

With Icelandic, Norwegian, and Danish, Swedish is a Scandinavian language, but Swedish and Danish form an East Scandinavian or East Norse group, characterized by, among other things, a monophthongization of the Old Norse diphthongs, *kaupa, bein,* and *heyra* having become *köpa, ben,* and *höra,* and by a tendency to unite the old masculine and feminine in a common gender. Swedish is differentiated from Danish by its retention of intervocalic *p, t,* and *k* (Sw. *slipa, eta, taka;* Dan. *slibe, de, ta*[*ge*]), by its preservations of different vowel qualities in endings, where Danish uniformly has *-e,* and by a musical word accent similar to that used in Norway. Both in forms and in pronunciation Swedish thus remains at an older stage than Danish. Like Danish and Norwegian, Swedish has been strongly influenced in vocabulary, especially by low German during the Hansa period and by French in the eighteenth century, though these influences are far less important than the French influence on English.

The Swedish standard written language is most closely related to the town dialects of central Sweden in Uppsala, Stockholm, and the towns of Södermanland. There are many and different dialects whose boundary lines in the

main cut across the country. To the south the dialects of Skåne, Halland, and Blekinge have been affected by their former subjection to Denmark. North of these follow the dialects of Gotland and then the dialects of central Sweden, bordered to the north by the dialect of Dalecarlia, beyond which the Norrland dialects stretch up to the boundaries of Norway and Finland. In the extreme north a Finno-Ugric dialect is spoken by the Lapps. Of the islands, Gotland has the most original dialect. The dialects of Finland are called East Swedish dialects. Runic inscriptions in Sweden date from the fifth century, the oldest manuscripts from about 1250. S. E.

**SWEDISH LITERATURE.** The old pagan literature in Sweden was destroyed when Christianity was introduced, but rock engravings and runic stones prove that Sweden in Viking times had a rich lyric and epic literature, equivalent to the Icelandic. In medieval literature, St. Birgitta's writings in the fourteenth century played a predominant part; but some historical chronicles are also preserved from that period, as well as poems, ballads, and folk songs. Olaus Petri, who introduced the Lutheran Reformation into Sweden in 1527, was an historian of real importance and has been called the father of Swedish prose. The abrupt severing of Catholic traditions resulted in a setback in Swedish cultural development, but in the reign of Gustavus Adolphus, at the beginning of the seventeenth century, there was an intellectual renaissance which put its stamp on Swedish literature. Lars Wivallius (1605-1669) was a widely read lyricist, and Georg Stiernhielm (1598-1672) published in 1658 the poem *Hercules,* written in hexameter on antique models. Other writers from the same century used Italian and French models in their poetry. Johan Runius (1679-1713) was perhaps the most popular poet of this period, but he stood aside from literary schools.

**Eighteenth Century.** During the eighteenth century the influence of French and English literature was strongly felt. Olof von Dalin (1708-1763) published a moral weekly, *Argus,* for which Addison's *Spectator* was used as model, and he also wrote a great epic, *Svenska friheten* ("Swedish Freedom"), which was influenced by Voltaire's *Henriade.* Of special interest in his *Saga om hästen* ("Saga of the Horse"), a political allegory. His feminine contemporary, Hedvig Charlotta Nordenflycht (1718-1763), reflected the influence of Rousseau; she was an ardent champion of French taste in literature and, in general, of the ideas of the Enlightenment. The foremost representative of the Enlightenment, however, was Johan Henrik Kellgren (1751-1795). Kellgren's early works were influenced by libertinism, but later his philosophy became more noble, showing an understanding of great humanitarian ideals. In his opposition to mysticism and superstition especially, an opposition typical of this period, he used his gift of satire with crushing effect. A new influence appeared in the work of Tomas Thorild (1759-1808), who belonged to a movement originating with Rousseau, which was represented in Germany by the writers of the *Sturm und Drang.* Thorild was a firm believer in the possibility that enlightenment might create a better world. He published a magazine in which he expressed his opinions on cultural and social problems, and once he declared: "I had only one thought in my life: to explain all nature and to reform the whole world." When he found that Sweden was too small a country for the world republic which he planned to establish, he left for England; but he soon returned to his homeland, later becoming a professor in a German university. Thorild was the great prose writer of the *Sturm und Drang* movement in Sweden. The movement's great poet was Bengt Lidner (1757-1793); but Thorild's dominant themes were strength and harmony, while Lidner regarded the miseries of life as a mystery he could never understand. Lidner's period of creation was very short, but some of his poems doubtless represent the best of the period. Among other poets of this era, Carl Gustaf af Leopold (1756-1829) and Anna Maria Lenngren (1755-1817) should be mentioned. In the 1790's the latter published several poems in a style of middle-class realism which made her one of Sweden's most popular poets. Jakob Wallenberg (1746-1778) and Karl Mikael Bellman (1740-1795) were the first humorists in Swedish literature. The former is remembered for his travelogue of a trip to China. Bellman began early as a poet and singer of his own songs. He took his models from Stockholm's lowest classes, whose life he depicted with pronounced naturalism and joyous grace.

**Romanticism.** From the earliest times the most popular tales in Sweden were the Icelandic sagas, of which printed as well as handwritten copies had spread all over the country. At the beginning of the eighteenth century several foreign short stories were translated into Swedish and accepted as folk literature. The first Swedish original novel published in the 1740's was influenced by the old sagas, even though, like the heroic novel in France, it referred to contemporary happenings. The sentimental family novels by Kotzebue and La Fontaine, which were very popular during the latter part of the eighteenth century, prepared the way for Romanticism. During the eighteenth century, the impetus in Swedish literature came primarily from France and England, but during the first decades of the nineteenth century, influences from Germany were strongly felt. The leader of the Swedish neo-Romantic school was Per Daniel Atterbom (1790-1855) who, as a student at Uppsala University, founded a literary society and edited a monthly magazine. His mythical plays, *Fågel blå* (1814) (Blue Bird), and *Lycksalighltens ö* (1824) ("Isle of Bliss") are the most typical products of the new movement. The transition from the old school to the new is represented by Johan Olof Wallin (1779-1839), the most important religious poet of Sweden. Eric Johan Stagnelius (1793-1823) is often mentioned as the most gifted poet of the neo-Romantic school. His poetry is characterized by a glowing passion and a pompous form, but it was only after his death, when his collected poems were published, that he won recognition. The first decades of the nineteenth century were the golden age of Swedish literature. In addition to writers already mentioned, Esaias Tegnér (1782-1846) and Eric Gustaf Geijer (1783-1847) produced works which are now looked upon as classics in Swedish literature. Tegnér's political pathos won him acclaim as Sweden's national poet, and his *Frithiofs saga* is often mentioned as Sweden's national epic. Carl Jonas Love Almqvist (1793-1866) was the most important novelist of the 1830's, and his large production marks the development from neo-Romanticism to a new realistic school. Fredrika Bremer (1801-1865) fought for equal rights for women and is often mentioned as the founder of this movement in Sweden. She pictured everyday life in her novels and short stories, which, together with her travelogues, were widely read. In the middle of the century—the age of post-Romanticism—there was a group of poets who identified themselves with political liberalism in Europe. In Sweden this liberalism was linked, as a rule, with Scandinavianism, a movement toward greater unity among the Scandinavian countries. The great poet of the time in the Swedish language was, however, Johan Ludvig Runeberg (1804-1877), a native of Finland. Runeberg advocated simplicity and

realism in poetry, but Romantic tendencies continued to live in the Swedish literature of both Sweden and Finland during the period of realism that he inaugurated. Zachris Topelius (1818-1898) is the most important representative of this late Romanticism. He was a lyric poet, but he also wrote charming stories for children, and his historical novels belong to the most widely read works in Swedish literature.

After the middle of the nineteenth century a new and rich era was inaugurated with Abraham Viktor Rydberg (1828-1895) and Carl Snoilsky (1814-1903). Rydberg came from the lower classes, had difficulty in obtaining an education, and wrote under the influence of the liberal ideas of his time; his poetry reflects a strong Romanticism imbued with a deep idealism that verges on mysticism. Snoilsky, even though an aristocrat by birth and in his outlook on life, tried to understand and promote the liberal ideas of his generation; impressions from southern Europe inspired him to write poems filled with a sense of beauty and the joy of life, but he is mainly remembered for his poems upon themes from Swedish history.

The public of the 1880's looked upon Rydberg and Snoilsky as the leading authors of the day, but in the history of literature it is August Strindberg (1849-1912) and other representatives of the new Naturalism who dominated the 1880's, just as Verner von Heidenstam (1859-1940), Gustaf Fröding (1860-1911), Selma Ottiliana Lovisa Lagerlöf (1858-1940), and others are identified with the new Romanticism of the 1890's. In his youth Strindberg had already emancipated himself from the spirit of philosophical idealism which then prevailed in Swedish university circles. In his drama *Mäster Olof,* first printed in 1878, he gave voice to revolutionary enthusiasm, but his study of Shakespeare seems to have been the first impetus toward the realistic style which he later developed. With *Röda rummet* (1879) *(The Red Room)* Strindberg wrote the first great social novel ever written in Swedish, and this novel made him the leader of an entire group of realistic authors. The discussion of social problems became one of his main interests. In *Giftas* (1884) *(Married)* he opposed the emancipation of women; but he also wrote novels having no social tendency—for example, *Hemsöborna* (1887) ("The People of Hemsö")—which is often mentioned as the best novel ever written on life in the Swedish countryside. The following year, he published *Fröken Julie* (variously translated as *Countess Julia, Miss Julia,* and *Julia*), constructed after Zola's theories of a naturalistic drama. At the end of the century he published two modern mystery plays, using a new technique, *Till Damaskus* (1898) ("On the Way to Damascus") and *Vid högre rätt* (1899) ("The Higher Court"). During the first years of the twentieth century, he published several plays, some of them having historical themes. His last important work was *Stora Landsvägen* (1909) ("The Great Highway"), in which he sought, in lyrical dramatic form, to find a solution for his stormy and contradictory life.

To the Naturalistic period in Swedish literature also belongs Victoria Benedictsson (1850-1888), who used the pen name Ernst Ahlgren. She published short stories illustrating life in southern Sweden and novels in which she discussed the ideas of the time. Gustaf af Geijerstam (1858-1909) was a popular author of realistic novels and plays, who kept his popularity even after the realism of the 1880's had been succeeded by the Romanticism of the 1890's. The most gifted poet of the group was Ola Hansson (1860-1925), who moved to Germany and had no real influence on the literary development in Sweden.

Oscar Levertin (1862-1906) was first influenced by Strindberg, but later became a close friend of Verner von Heidenstam (1859-1940), with whom he co-operated in introducing the new Romanticism of the 1890's. Levertin, a learned scholar having a great love for Sweden's cultural traditions, also was important to the literary development in Sweden as a critic. The literary leadership, however, belonged to Heidenstam, who spent several years in southern Europe and in the Orient, studying art and the history of culture before he published, at the age of twenty-nine, his first collection of poems, *Ur Vallfart och vandringsår* (1888) ("Pilgrimages and Years of Wandering"), which aroused immediate admiration. His glorification of youth and beauty, the pleasure of the moment, and the unlimited power of love fascinated a generation which had been taught to admire utilitarian ideals and an art dependent on observable fact. Heidenstam regarded naturalism as a literary method that belonged to the past, and he felt that a new aesthetic must be ushered in if Swedish literature was to retain its vitality and significance. Sweden, in Heidenstam's opinion, actually needed an entirely new national literature. A movement toward this goal has been characteristic of the literary development in Sweden since 1900, and in it Heidenstam's influence has been strongly felt. He published several historical novels, but despite his deep interest in the past, he was never guilty of narrow antiquarianism. He explored Sweden's national past in order to interpret and, if possible, to direct Sweden's national present and future. One of the ideas most frequently recurring in his works is that the only solution to the many problems of his generation was the return to an essentially Classical spirit and point of view. In his opinion, some form of modern humanism was a philosophical and aesthetic necessity for the modern world.

In a letter to Heidenstam, Levertin said that Selma Lagerlöf's novel, *Gösta Berlings saga* (1891) was the "first work in accordance with Heidenstam-Levertin aesthetics," even though he was not quite sure of its qualities. Selma Lagerlöf, from childhood, had been the recipient of a rich store of local legends, but not until she had left her home province, Värmland, did she become conscious of the possibilities of its tales and legends as material for literature. Selma Lagerlöf was a born storyteller, able to fascinate her public, and gifted enough to rehabilitate the Swedish novel. The success of *Gösta Berlings saga* made it possible for her to travel around the world. *The Miracles of Anti-Christ* (1897) is a description of Italian village life, and at the same time an expression of the author's interest in social problems. In *Jerusalem* (1901-1902), she told a story for which she could use provincial Sweden as well as the Orient as a background. In 1908 Selma Lagerlöf moved back to Värmland and settled down in her old home for the remainder of her life. Her subsequent production was very rich, and its delicate art and warm humanity confirms, if it does not add to, the reputation she won for *Gösta Berling* and *Jerusalem.*

Heidenstam's ideas also inspired Gustaf Fröding (1860-1911), a Swedish newspaperman, to make his first appearance as a poet. Unexcelled as a master of form, Fröding inaugurated a renaissance in Swedish poetry. His poetry covers a wide field, which includes folk life in Värmland, his home province, and a brooding over moral and religious problems. Erik Axel Karlfeldt (1864-1931) converted the old peasant civilization of his home province, Dalecarlia, with its echoes of Biblical and folk wisdom, into great poetry. Pelle Molin (1864-1896) represented north Sweden. The last one of the great generation of the 1890's was Per Hallström (1866- ). He often painted life in dark colors, but some of his best works are rich in genuine Romanticism.

**Twentieth Century.** In speaking of the 1880's and the 1890's as two great periods in Swedish literature, it should be remembered that some of the foremost representatives of these two periods created many of their best works in the twentieth century, when they also became more widely read and recognized. The social development of the time allowed a greater literary interest among the common people, and the national movement, represented in the 1890's by Verner von Heidenstam, included a new interest in folk culture and regional history, and also efforts to make the national treasures in literature and arts available to the common man. Temperance and religious activities were other details of the nationwide idealistic movement. A typical representative of the combination of an interest in folk culture and a general social sympathy is Karl Erik Forsslund (1872-1941), whose novel *Storgården,* a modern variation of Rousseau's theories, was widely read. Forsslund founded a people's high school at Brunnsvik, where later a whole generation of intellectuals from the working class completed their education, many of them becoming poets and novelists.

The labor movement, in its early stages, produced no poets of importance. Younger poets and novelists of the new century had a pessimistic outlook and a *fin-de-siècle* philosophy, influenced from abroad. Typical representatives of this group are Hjalmar Söderberg (1869-1941) and Bo Bergman (1869- ), both Stockholm writers. In southern Sweden a contemporary group followed the traditions of Ola Hansson, among whom Vilhelm Ekelund (1880- ) and Anders Österling (1884- ) should be mentioned. A movement toward realism and a greater interest in social problems set in around 1910. A forerunner of this movement was Albert Engström (1869-1940), who criticized the artificial psychological interest of his colleagues and pictured life in Småland. Ludvig Nordström (1882-1942), like Pelle Molin, was a literary representative of north Sweden. Hjalmar Bergman (1883-1931) capitalized on his knowledge of life in central Sweden in his novels. Sigfrid Siwertz (1882- ) also belongs to this group. His writings are intellectual and reflect Swedish contemporary life. This is also true of Gustaf Hellström (1882- ), who during his many years as a newspaper correspondent in foreign countries has been interested in psychological and sociological problems. Selma Lagerlöf's place in the Swedish Academy was taken by Elin Wägner (1882-1949), who painted colorful pictures of the early years of women's emancipation in Sweden. In her later novels, Elin Wägner's interest shifted to moral problems.

Martin Koch (1882-1940) gave Swedish literature its first thorough portrayal of the working class and its special conditions of life. In trying to picture the lives of individuals, he also wanted to write novels concerning the history of the community. The same ambition is typical of the self-educated radical politician and writer Fabian Månsson (1872-1938). The influence of World War I on Swedish literature is especially recognizable in efforts toward a deeper understanding of the problems of the time, characteristic of an entire group, and it is the more significant in that many of the group had begun as dilettantes influenced by *fin-de-siècle* motifs in Scandinavian literature. This development has also contributed to a better appreciation of the entire "group of the 1910's," which, to a great extent, had been overshadowed by the authors of a previous generation. Some of the poets in the period after World War I tried to express the "agony of life" felt in a world torn by war and disaster. Several of them turned to religion, hoping there to find a solution of their problems; to others the creative forces of life, true love, duty, home, and tradition became sources of inspiration. Sometimes these poets have been criticized for having cultivated the idyl for its own sake, but the seriousness of their attitude cannot be doubted. During the 1920's they were opposed by a group of authors from the working class, who cared less for tradition and cultural heritage than for the right of spontaneous life and the satisfaction of primitive instincts. Of the group from the 1920's, Birger Sjöberg (1885-1929), Dan Andersson (1888-1920), and Erik Lindorm (1889-1941) should be mentioned. To the group of poets for whom sober reality and the greatness of everyday life are the sources of inspiration belong Karl Asplund (1890-1949) and Gunnar Mascoll Silfverstolpe (1893-1942). Sten Selander (1891- ) stands between this group of lyricists of the 1920's and a group of authors whose works almost exclusively concentrate upon the discussion of philosophical ideas. Among the latter, Pär Lagerkvist (1891- ) and Erik Blomberg (1894- ) should be mentioned.

After World War I interest in literature grew steadily in Sweden. Adult education received more support and the number of libraries increased. Literary interest among the working classes became apparent, and most of the new authors in the 1930's were young workers lacking college or even high school education. Several of them, however, spent some time abroad and received deep impressions of foreign literature. Psychoanalysis was their favorite science; it served as an arsenal for their opposition to old forms and conventional ideas. Discussion of social, religious, and cultural problems was intense during the first years of the decade, but it was later overshadowed by the threat of World War II. One of the most colorful authors was Agnes von Krusenstjerna (1889-1940), whose intensity and interest in the psychology of the abnormal recalls Hjalmar Bergman. A more intellectual and broadminded psychologist was Eyvind Johnson (1900- ), who in his autobiographical novels provided a study of the psychology of youth unsurpassed in Swedish literature. Among the authors of the same generation who depict life in the Swedish countryside, Vilhelm Moberg (1898- ) holds first rank because of his honest, reliable, and naturalistic portrayal of the peasantry. Ivar Lo-Johansson (1901- ) added to Swedish literature a Swedish farm laborers' epic, written with passion and strength, a realistic description of a proletarian background. Helga Martinson (1890- ) and Jan Frigegård (1897- ) also belong to this group. The group of authors who called themselves "the five young ones" who, about 1930, prophesied a new and better era, the age of a generation free from complexes, began as modernistic poets, but seemed in spite of their program, to be more at home with the idyl than with the trappings of the machine age. This is especially true of Harry Martinson (1904- ), who sketched life at sea and in harbors in prose unsurpassed in modern Swedish literature. The leader of the group was Artur Lundkvist (1906- ) whose enthusiastic praise of the joy of life is in contrast to the pessimism and inharmonious feelings met in poets such as Birger Sjöberg, Bertil Malmberg, and Pär Lagerkvist. Hjalmar Gullberg (1898- ) has felt the agony and pessimism of two world wars. His deep feelings and intellectual skepticism give his enthusiasm and irony a richer register than most of the writers of his generation. Influences from American modernists inspired the generation of the 1940's to literary experiments which promised to inaugurate a new development.

The Romanticism in Finland's Swedish literature, represented by Topelius, was broken by Karl A. Tavaststjerna (1860-1898), who was influenced by Henrik Ibsen and Strindberg. The literary development after Topelius and

Tavaststjerna remained dependent on the political development of the time. Authors and poets felt it their duty to defend Finland's cultural traditions against Soviet pressure. The competition between the two official languages in Finland—Swedish and Finnish—has also been strongly felt. Hjalmar Procopé (1868-1927) was the oldest of a group of gifted poets embodying Swedish traditions from the 1890's. Bertil Gripenberg (1878-1947) represented the province of Tavastland (Häme). Arvid Mörne (1876- ) represented the province of Nyland (Uusimaa), and Jakob Tegengren (1875- ), the Swedish-speaking province of Österbotten (Vaasa). Among the novelists, Runar Schildt (1888-1925) might be mentioned, and Jarl Hemmer (1893-c. 1944) discussed ethical problems in his poetry as well as in his novels. Modernistic trends were represented by Edith Södergran (1892-1923) and Elmer Diktonius (1896- ). *See also* Almqvist, Carl Jonas Love; Andersson, Dan; Bellman, Karl Mikael; Fröding, Gustaf; Heidenstam, Verner von; Kellgren, Johan Henrik; Lagerlöf, Selma Ottiliana Lovisa; Runeberg, Johan Ludvig; Söderberg, Hjalmar; Södergran, Edith; Strindberg, August; Tegner, Esaias; Wallin, Johan Olof. A. Wi.

**SWEET, HENRY** (1845-1912), English phonetician and philologist, was born in London, Sept. 15, 1845. He began an independent study of Old English in 1863 and of phonetics in 1868, meantime studying at King's College, London, at Balliol College, Oxford, and at Heidelberg University. Later he edited some of the most important Old English texts for the Early English text society: King Alfred's *Cura Pastoralis* (1871), *Orosius* (1882), and the *Oldest English Texts* (1885). From 1873, he produced books which laid the foundation of modern phonetics (*History of English Sounds,* 1873; *Handbook of Phonetics,* 1877; and other works) and of formal instruction in Old and Middle English (*Anglo-Saxon Reader,* 1876; Middle English primers in 1885 and 1891; and other highly competent texts). He also wrote important works on the history of English and on general linguistics. Sweet was intensely disappointed when his two applications for a professorship at Oxford (1885, 1901) proved futile; Oxford granted him only a readership in phonetics (1901). His practical work in phonetics continued throughout his life. He died at Oxford, Apr. 30, 1912. C. R. Sl.

**SWEET ACACIA** [ə-ke′shə], a plant, *Acacia farnesiana,* whose flowers are used in France in the making of perfumes. Native to tropical and subtropical America, it is naturalized throughout the warm regions of the world. A branchy, spiny shrub, or small tree, growing to about 12 ft. high, it is of the mimosa group in the pea family. It bears finely divided leaves and small globes of deep-yellow flowers with only the numerous stamens showing. The sweet acacia is also known as opoponax, popinac, cassie, and, in Mexico, huisache. J. C. Wis.

**SWEET BAY,** an attractive species of magnolia, *Magnolia virginiana,* native from Massachusetts to Florida and Texas. It is a shrub or tree growing as high as 60 ft., and has fragrant, creamy-white flowers in late spring. In the Old World, the name of this species is applied to the true laurel, *Laurus nobilis.* J. C. Wis.

**SWEET BRIAR COLLEGE,** an accredited, privately controlled college of liberal arts and sciences for women. The buildings and grounds occupy nearly 3,000 acres of land in the small rural community of Sweet Briar, Amherst Co., Va. The charter was granted in 1901 and first instruction was offered in 1906. Only the A.B. degree is offered. The junior year of study may be taken abroad in France and Switzerland under the foreign-study plan of the University of Delaware, or at St. Andrews University in Scotland. The extensive library contains a noteworthy collection of the works of George Meredith. All students, except residents of Amherst Co., live in the college dormitories. Special aid is given to a limited number of foreign students, and residents of Amherst Co. receive free tuition. The opportunities for self-help are limited. There are no sororities. *For statistics see* Colleges and Universities. J. R. To.

**SWEETBRIER,** a large vigorous species of rose, *Rosa eglanteria,* called also eglantine, native to Europe. The foliage is fragrant. This rose is naturalized throughout eastern North America. J. C. Wis.

**SWEET CLOVER,** common name of a genus, *Melilotus,* of erect fragrant herbs of the pea family, also called melilot. All of the approximately 30 species are natives of the Old World, but some are widely naturalized in fields and along roadsides in North America. One of the best known of these is the white sweet clover, *M. alba,* which grows across the United States and is widely sown, under the name Bokhara clover, for green-manuring, for forage, and as a cover crop. It is a biennial growing 3 to 10 ft. high, and has fragrant leaves, divided into three small leaflets, and many slender spires of small white flowers which are a fine source of honey. The annual yellow melilot, *M. indica,* from Asia, is a smaller plant having yellow flowers, much grown in California, and widely naturalized. The larger common yellow sweet clover, *M. officinalis,* of Europe and Asia, is also widespread in North America. E. R. C.

**SWEET FLAG,** common name for an aromatic perennial species, *Acorus calamus,* of the arum family, growing in swamps and along streams throughout eastern North America, in Europe, and in Asia. The leaves are linear and pointed, from 2 to 6 ft. in height, and the tiny, greenish-yellow flowers are produced in early summer on short spikes projecting laterally from leaf-like stalks. In North America, the plant rarely produces fruit. The horizontal branching rootstock serves as a means of propagation, and its highly aromatic character makes it useful in medicines, flavorings, and perfumes. J. A. Bo.

**SWEET GALE,** called also sweet willow and bog myrtle, an aromatic shrub, *Myrica gale,* of the sweet-gale family, native to wet, peaty soils throughout the arctic and cool temperate regions of the Northern Hemisphere. It grows 2 to 5 ft. tall, bearing narrow, wedge-shaped leaves dotted with resin, and small flowers in short, dense catkins which appear before the foliage does. The yellowish fruit is resinous, but, unlike the fruits of the closely related bayberry, has no wax coating. The sweet gale is an emblem of the Scottish clan of Campbell. *See also* Wax Myrtle. J. C. Wis.

**SWEETGUM.** *See* Liquidambar.

**SWEETLEAF,** a partially evergreen tree, *Symplocos tinctoria,* of the sweetleaf family, found in moist, shady places from Delaware to Florida and Louisiana. It grows as high as 30 ft. The narrow, oblong leaves, lustrous above and silvery-white below, are greedily eaten by cattle and

horses because of their sweet taste, which gives the tree the alternate name of "horse-sugar tree." In spring, there are profuse clusters of fragrant yellowish flowers. A yellow dye is obtained from this tree. W. D. B.

**SWEET PEA,** a slender climbing annual, *Lathyrus odoratus,* of the pea family, grown in gardens and under glass for its delicate, fragrant flowers carried on long, slim stalks. Native to southern Europe, the sweet pea was first cultivated in Sicily in 1699. Years of selective breeding by many growers have produced sweet peas ranging from white through pink, red, yellow, and blue, with variations in the ruffling of the flowers, in the height of the plants, and in time of bloom. The dwarf sweet pea, var. *nanellus,* is a low plant which succeeds in climates too hot and too dry for the six-foot, tendril-climbing varieties. The development of a winter-flowering strain for greenhouse cultivation has given the sweet pea a place among the five leading commercial cut flowers. The production of sweet pea seed is a California industry. J. C. Wis.

**SWEET POTATO,** *Ipomoea batatas,* a perennial of the morning-glory family, grown for its edible tuberous roots. Some botanists think this plant is native to the Old World; others maintain that it may be a cultigen of *I. tiliacea,* a closely related species native to tropical America. The creeping stems bear long leaves and rose-violet or pale pink flowers. The plant requires fertile land of good tilth. It is widely cultivated in warm regions and in the United States is grown commercially from New Jersey southward and westward to Southern California. It is often erroneously called the yam. V. A. T.

**SWEETSOP,** a small tree, *Annona squamosa,* of the custard-apple family, growing 10 to 20 ft. high, and bearing oblong leaves and greenish-yellow flowers. The fruit is about the size of an orange, smooth, somewhat globular, and yellowish in color. It has a sweet, custardlike flavor. This tree, which is also called the sugar apple, is native to tropical America; its fruit is used in making preserves and jellies, and for this reason it is widely cultivated in warm regions. M. G. W.

**SWEET SULTAN.** *See* CENTAUREA.

**SWEET VERNAL GRASS,** *Anthoxanthum odoratum,* a perennial, native to Europe and Asia but now naturalized in all parts of North America. The erect, 2-ft. stems bear short leaves and spikelike flowering panicles. It is often planted with other grasses for the fragrance (due to coumarin) which it yields when dry. J. C. Wis.

**SWEETWATER,** a city and resort in north central Texas, the county seat of Nolan County, situated 176 mi. southwest of Fort Worth in an agricultural and livestock area famous for its Hereford cattle. The city is a cattle-shipping, trade, and distribution center for the entire county. Gypsum is a natural resource of the region. Sweetwater was founded in 1877 and incorporated as a city in 1895; it has the council-manager type of government. A historic feature in the vicinity is the ruins of Fort Chadbourne, established in 1853. The Sweetwater region is the locale of Dorothy Scarborough's novel, *The Wind,* dealing with the devastating drought of 1886 and 1887. Transportation is furnished by the Atchison, Topeka and Santa Fe and the Texas and Pacific railroads, and by the Pioneer Airlines. Railroad shops are important in the city's economic life. Industries include meat packing, oil refining, and the manufacture of cake and mixed feeds, gypsum products, cottonseed oil, and creamery products. Pop. 1950, 13,619.

**SWEET WILLIAM,** a perennial, *Dianthus barbatus,* of the pink family, closely related to the garden pink and native to Europe and Asia. Long a garden plant, it has become naturalized in parts of the eastern United States. Strong, erect stems, 1 to 2 ft. high, bear broad, pointed leaves, and close, rounded heads of flat, fringed flowers in red, purple, rose, or white. There are many horticultural forms, usually treated as biennials, including single and double varieties. Hybrids have been developed also with other species of *Dianthus.* In the middle western states, the name "wild sweet William" is applied to the native *Phlox divaricata.* E. L. Sh.

**SWEYN, SVEIN, SVEN,** or **SVEND** [svɛ′ɪn, svɛ′n], the name of three kings of Denmark.

**Sweyn I** (d. 1014). Though his father, Harold Bluetooth, had Christianized the Danes, Sweyn I, called Forkbeard, threw off Christianity and, after taking part in numerous Viking expeditions, deposed and killed his father in 986. Shortly after ascending the throne he was driven from Denmark by Eric, king of Sweden, and in 994 began his raids against England, compelling Ethelred the Unready to pay him tribute, but failing to take London. Eric having died in 995, Sweyn returned to Denmark and in 998 married Eric's widow, Sigrid, who persuaded him to form an alliance with the Swedish king, Olaf, against Olaf Tryggvesson, king of Norway. In 1000 the allies were victorious at the famous battle of Swold, off Rügen, at the same time conquering southern Norway. The massacre of Danes in England on St. Brice's Day, 1002, in which Sweyn's sister was killed, drew him once more to England, and by the end of 1013 he had conquered nearly the whole of that kingdom. Sweyn died suddenly at Gainsborough on Feb. 13, 1014. His conquests in Norway and England laid the foundation for the power of Denmark in the Middle Ages.

**Sweyn II, Estrithson** (d. c.1075). Sweyn II was the grandson of Sweyn I and the nephew of Canute the Great. After the murder of his father, Earl Ulf, by Canute (c. 1027), he fled to Sweden, where he remained until 1035, when he was named viceroy of Denmark by Magnus the Good, King of Norway. Magnus became king of Denmark in 1042 and, before his death in 1047, appointed Sweyn his successor to Denmark's throne. For 17 years Sweyn waged an inconclusive war against his rival, Harold III, called Hard-Ruler, heir to the throne of Norway, and twice, in 1069 and 1075, unsuccessfully attempted to invade England and seize the throne of that country. He was the founder of the Estrith Dynasty and five of his sons became kings of Denmark.

**Sweyn III** (d. 1157). Sweyn III was the son of Eric II, the Memorable. Brought up at the court of Conrad III, Sweyn succeeded to the throne of Denmark on the abdication of Eric III, the Lamb, in 1147. His entire reign was marked by struggles with the rival claimants to the throne, Canute V and Waldemar I. Though he succeeded in assassinating the former, he was himself defeated by Waldemar at the battle of Grathe Heath in 1157, and perished in his flight from the field. C. W. D.

**ŚWIDNICA** [shvidni′tsɑ] (Ger. Schweidnitz), an industrial city in Wrocław Department, southwestern Poland, 30 mi. southwest of the city of Wrocław. The former German city lies on the upper Weistritz River at the northeast

foot of the Eulen Range, part of the Sudeten Mountains, on the Czech frontier. Originating about the eleventh century, it received town rights in 1250 and was in the fourteenth century the capital of a partial principality of the Piast dukes. It passed to Prussia in 1741, was fortified by Frederick the Great in 1747, occupied by the Austrians (1757-1759, 1761-1762) in the Seven Years' War, and occupied by the French under Napoleon. It was later included in the Prussian province of Lower Silesia. In 1945 it was taken by Soviet troops and provisionally awarded to Poland at the Potsdam Conference. The Roman Catholic Parish Church, built between the fourteenth and sixteenth centuries, has a 328 ft. tower, one of the highest in Silesia. The town hall was first built in 1291, and rebuilt in 1717, while the Church of Peace was built in 1652. Świdnica has a museum containing articles associated with the noted German World War I flier, Manfred von Richthofen. The local factory output prior to World War II included electric clocks, radio supplies, machines, sporting goods, leather, furniture, and beer. The town was a trade center for grain, lumber, and cattle. Pop. 1946, 13,106. L. M. A.

**SWIFT, JONATHAN** (1667-1745), English author, was born in Dublin, Nov. 30, 1667, the son of an English family that had recently settled in Ireland. Though he wrote a considerable body of poetry, he is chiefly famous for his prose writings, and in particular for his brilliant and vigorous satires.

After leaving Trinity College, Dublin, he spent ten years, from 1689 to 1699, with several interruptions, in the household of Sir William Temple, Whig statesman and minor author, at Moor Park, forty miles from London, as confidential secretary. His duties left him time to read widely in Temple's excellent library. It was here, during the years 1696 and 1697, that he probably composed his first great satire, not published until 1704, *A Tale of a Tub*. Inferior to *Gulliver's Travels* in universality of appeal, it even surpasses *Gulliver* in sheer energy of intellect and in the telling vigor of its prose. He had been ordained priest in the (Anglican) Church of Ireland in 1695, and on Temple's death in 1699 he settled in his Irish parish at Laracor, about forty miles from Dublin. During the next ten years he lived in Ireland, with a number of protracted visits to England, serving on one of them as official representative of the Irish Church in some financial negotiations with the English government.

Swift was brought up a Whig; but he became convinced that under the Whigs the established Church was in danger. In 1710 he joined the Tories and for the next four years threw himself into the support of the Tory administration of Edward Harley and Henry St. John. His vigorous political writing and his shrewd political advice made him during these years one of the most influential men in all England.

With the death of Queen Anne (1714), the Tory Party fell from power and went into a long period of eclipse. Swift's career in English politics was at an end. To Swift and to his friends the ascendancy of the Whigs seemed a triumph of all the base and ignoble forces in English life. For such services as he had rendered, an eighteenth-century clergyman could expect to be rewarded by being made a bishop; but Swift received only an appointment as Dean of St. Patrick's Cathedral, Dublin.

A disappointed and embittered man, Swift, then forty-seven years old, took up his residence in his Dublin deanery where, with only two visits to England, he spent the remaining thirty-one years of his life.

Into his life there came an element of strange romance that has fascinated and baffled all students of his life and writings. During the years of his political prominence he had met a young woman of twenty, daughter of one of his London neighbors, named Esther Vanhomrigh, whom Swift called "Vanessa" in his writings. She fell desperately and passionately in love with him. Much against his wishes, she insisted on following him to Ireland, where she died in 1723, almost literally of a broken heart. More important is "Stella," Miss Esther Johnson. When Swift first knew her, she was living with her mother, housekeeper for Swift's employer Sir William Temple. She was a graceful child of eight, Swift a rather awkward youth of twenty-two. Among his duties was that of acting as tutor for the little girl, for whom Temple felt a deep affection. She grew up to be an extremely beautiful and gracious woman. Sir William died in 1699, and two years later the girl went at Swift's suggestion to Ireland, where she lived under Swift's care and protection until her death twenty-seven years later. To her he addressed during the years of his political activities the famous series of diary-letters, published after his death as *The Journal to Stella*. She was the closest and dearest of Swift's many close friends; but his affection for her was as sexless as that of an uncle for a gracious and charming favorite niece. By a punctilious observance of the proprieties—they were never alone together—the breath of scandal was turned aside; but rumor had it that they had been secretly married. This rumor, accepted as fact by many of Swift's biographers, seems to others an improbable story resting on very insufficient evidence. All, however, are agreed that Swift and Stella never lived together as man and wife.

For several years after his return to Dublin as Dean, Swift wrote nothing of consequence. Then in 1724 he emerged in the *Drapier's Letters* as an Irish patriot protesting against the economic bondage in which Ireland was held by her English overlords. In 1726 was published his most memorable work, *Gulliver's Travels*. Instantly popular, it has continued to be one of the most widely read books in English. It is a fascinating play of fanciful imagination and a profound satire on the essential unreasonableness of human behavior.

All his life Swift had been subject to periods of depression and to a haunting fear of insanity. After Stella's death in 1728 his gloom steadily increased. His last years were passed in a dreadful apathy, his mind clouded, his speech nearly gone. And there were periods of intense pain. He died on Oct. 19, 1745, at the age of seventy-eight, and was buried beside Stella in the nave of St. Patrick's Cathedral. The Latin epitaph, by Swift himself, contains the statement that he now is laid "where fierce indignation cannot any longer tear his heart."

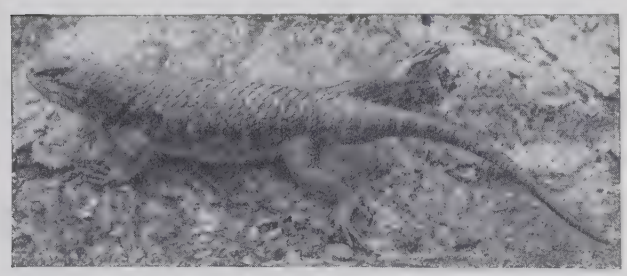
With brilliant wit and fertile imagination, in a prose style unsurpassed for its unadorned vigor, he indignantly lays bare the manifold corruption that lurks beneath the plausible surface appearance of men and their social behavior. In every one around him—even in his dearest friends and in himself—he sees the latent beast, and at the dreadful spectacle he tears his heart. If only, he seems to say, men could cease to be ruled by their mean and sordid passions and live by the clear light of reason! *See also* Battle of the Books, The; Gulliver's Travels; Tale of a Tub, A. R. K. R.

**SWIFT,** any one of a large number of species of small birds that form the family Chaeturidae. Although quite different in appearance, their nearest relatives are the hum-

mingbirds. They occur in temperate and tropical regions virtually throughout the world. They are characterized by a truly streamlined body with extremely long, narrow, backward-curved wings, a large mouth for capturing insects, and small, weak feet that can support them only while clinging by the claws to a vertical surface. In many ways they resemble the unrelated swallows, with which they are popularly confused. Their plumage is dull, usually combining such colors as browns, grays, black, and white, but in some cases showing a more or less metallic gloss. Most swifts build shallow, cuplike nests of twigs, affixed by a gluelike secretion of the salivary glands to the walls of caves, chimneys, or hollow trees. Their voices are shrill and grating. The members of this family are the most aerial of all birds; they eat and even drink while in flight. The wings are beaten with great rapidity, and some of the larger species of swifts are known to achieve for short distances a speed in excess of one hundred miles an hour. The North American members of this group vary in size from 5½ to 7½ inches in length. H. G. De.

**SWIFT CURRENT,** a city in Saskatchewan, Canada, on the Swift Current Creek, 110 mi. west of Moose Jaw. Located in a grain-growing and mixed-farming region, it is a commercial and distributing center for southwestern Saskatchewan. The Canadian Pacific Railway provides transportation for this industrial center, which includes among its industries four grain elevators, and a flour mill. A Dominion experimental farm is located near the city. There is a meteorological station situated in Swift Current. Pop. 1951, 7,458. L. G. R.

**SWIFTS,** a name loosely applied to various small, speedy, diurnal lizards. They are very hard to differentiate from one another, and they are hard to capture. There are four



VERNON BAILEY—U. S. FISH AND WILDLIFE SERVICE

*SWIFT, A LIZARD BELONGING TO THE GENUS* SCELOPORUS

genera of swifts. The rough-scaled swifts, *Sceloporus,* a genus with 102 members, has 27 representatives in the United States. They are found from British Columbia to New York, and south to Panama. They all are without a fold of skin across their throats; some of them are egg-laying, while others are live-bearing. The other three genera are also known as utas. They are all egg-laying, and all have a fold of skin across their throats. They are found in the western United States and in Mexico. The utas include 2 species of collared utas, *Streptosaurus;* 20 species of climbing utas, *Urosaurus;* and 11 ground utas, *Uta.* M. G. N.

**SWIMMING AND DIVING.** The art of swimming and diving, as practiced by man, dates back to prehistoric times. As a popular sport, however, its development did not begin until the late nineteenth century, when new strokes were introduced in competition. Developments since the turn of the century have classified swimming and diving as a distinct form of recreation and a competitive sport.

**Early History.** Prehistoric man began the development of swimming when he took to the water for the preservation of life, to cross unfordable streams, or to bathe for comfort. Literature and sculpture prior to A.D. 1500 supply many references showing that swimming was in common use among people of many races. The ancient Assyrian bas-reliefs, from the period about 880 B.C., show soldiers propelling themselves in the water by an overarm stroke resembling the modern crawl stroke. The Greeks and later the Romans, both physically active races, found swimming valuable training for military service and a healthy recreation during peace. When Leander conquered the Hellespont in A.D. 193, the coin of Abydos was struck off to commemorate the event. He used an overarm stroke, also popular with the Romans, that is believed to have come from the early Assyrians. Tales of other great feats of swimming are found not only in Greek and Roman Classics but in the early Scandinavian sagas, and in the first bit of English literature known, the epic poem *Beowulf.*

Plagues sweeping Europe during the Middle Ages discouraged swimming, since it was generally believed that outdoor bathing was a contributing factor in the spread of disease. The art did not vanish entirely, however, and European literature, beginning in the late sixteenth century, contains further references. During the next three hundred years there was considerable experimentation on swimming strokes. At first a breast stroke came into common use. This yielded in popularity to an underarm side stroke and various forms of an elementary backstroke. Finally, an overarm side stroke came into vogue and was employed extensively, particularly in England, until the turn of the twentieth century.

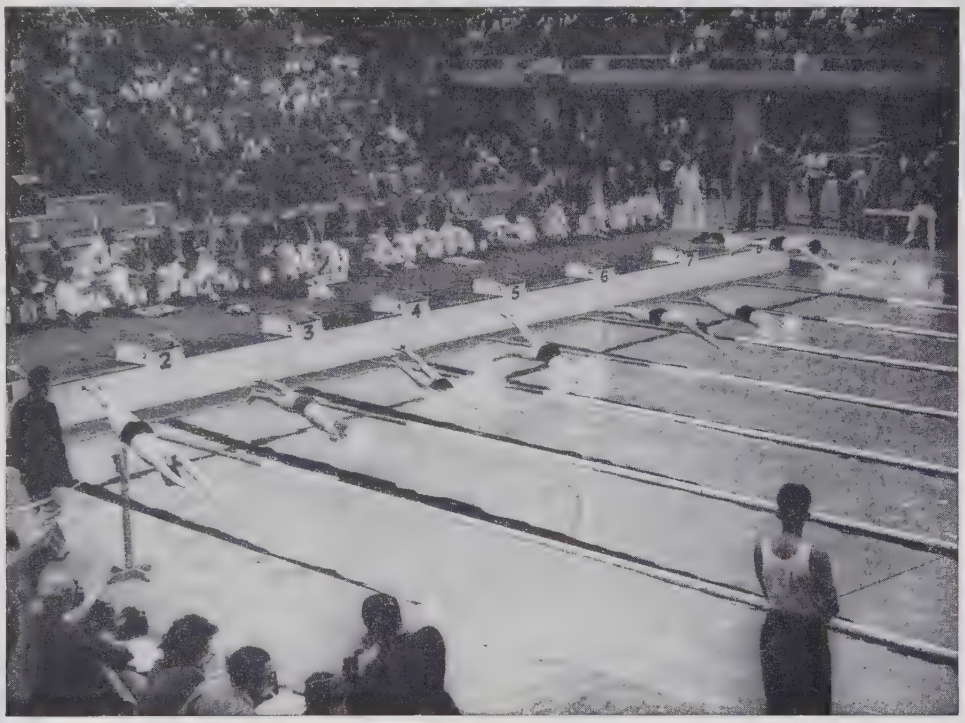
**Start of Competitive Interest.** The start of competitive activity in swimming stimulated public interest and an ever-increasing participation in swimming. It focused attention upon the form and style of various strokes, led to the revival of the ancient Olympic Games in 1896, and set in motion the great assault upon time records in the various accepted events and distances.

The Associated Metropolitan Swimming Clubs of London were organized in 1862 to promote competitive swimming. This group was the forerunner of the London Swimming Association, which later became the Amateur Swimming Association of Great Britain, with a total membership of three hundred clubs. Simultaneously, swimming gained in popularity in central Europe, Australia, and New Zealand. In the United States, the sport was given new impetus by the formation in 1888 of the Amateur Athletic Union, a "union of clubs" with the specific purpose of promoting amateur athletics, including swimming.

**Development of Strokes.** *Crawls.* The developing accent on speed led to the introduction in England in 1873 of a new hand-over-hand racing stroke. J. Trudgen, who first adapted the stroke, had learned it from the South American Indians. Because of the remarkable speed he was able to attain with it at sprint distances, the stroke caught and held the public fancy. It was essentially a crawl overarm stroke. The Australian crawl stroke came soon after. This was a slight modification of a stroke long used by the native South Sea islanders and was first introduced in competition in about 1900 by Richard Cavill, an Australian, who broke the existing world's record for 100 yd. with ease. The manner in which he seemed literally to "crawl over the water," according to sports accounts of

the race, established the name of the stroke in popular fancy.

After the Americans had turned serious attention to racing in the water, they modified the Trudgen and Australian crawl strokes and introduced a six-beat kick, combined with a double overarm stroke now commonly known as the American crawl. "Free style" means any style of swimming. It is the name for those competitive events in which any type of stroke may be used. Since the crawl stroke became the fastest method for getting through the water, it has become nearly synonymous with free style. In the crawl, the great free-style stroke of the champions, the position of the body is in a face-down float. The arms alternate in reaching out over the shoulder, while the leg drive is a continuous up and down thrashing motion from the hips down.



THE MEN'S 1500-METER FREE-STYLE FINAL AT THE OLYMPIC GAMES

INTERNATIONAL NEWS

*Backstroke.* The modern backstroke, or back crawl, is a combination of the overarm action with a flutter kick. It is actually an inverted crawl, involving certain adjustments, with the same co-ordination between the arm and legs, and is both powerful and speedy.

*Breast stroke.* The ancient and orthodox breast stroke, celebrated by Lord Byron in his poetry and believed by some to be the oldest of all strokes, was considerably speeded up by the introduction in 1935 of a "butterfly" racing adaptation by Henry Myers, an American. In this adaptation, recovery of the arms takes place out of the water, resembling somewhat the flapping of a butterfly's wings. In the older and considerably slower breast stroke, recovery of the arms takes place under the water.

**Olympic Games.** Only three swimming events were held at the 1st Olympiad at Athens in 1896; these were free-style races at 100, 500, and 1,200 meters. Races at various distances were held in the 1900, 1904, and 1906 games, but it was not until 1908 that the current Olympic swimming program was established: free-style races at 100, 400, and 1,500 meters; free-style relay at 800 meters; backstroke race at 100 meters; and breast-stroke race at 200 meters. The first American Olympic swimming champion was Charles M. Daniels, who won free-style races at 220 and 440 yards in 1904, and went on to win the 100-meter free style in 1906 and 1908; he remains the only swimmer ever to win four Olympic championships. For a decade after World War I the United States dominated Olympic swimming, winning 13 of a possible 19 titles at the 1920, 1924, and 1928 games. Japan, however, won five of six events in 1932, and three of six in 1936. America regained pre-eminence after World War II, winning 10 of 12 titles at the 1948 and 1952 games.

Women's swimming events were introduced in 1912 at the 5th Olympiad at Stockholm, but it was not until 1924 that the standard Olympic program (100- and 400-meter free style; 400-meter free-style relay; 100-meter backstroke; and 200-meter breast stroke) was established. Ethelda Bleibtrey, who won two races in 1920, was the first American woman to win an Olympic swimming championship. American women dominated the games from 1920 through 1932, winning 14 of 19 events in that time. The Netherlands, with four titles, was outstanding in 1936, while in 1952 Hungary won four of the five swimming events.

**Great Champions.** *Free Style.* The first great American free-style champion was the Olympian, Charles M. Daniels. Others who followed him include Duke Kahanamoku, Johnny Weissmuller, Norman Ross, Walter Spence, Peter Fick, Ralph Flanagan, Clarence L. "Buster" Crabbe, Otto Jaretz, Jack Medica, Keo Nakama, Alan Ford, Wally Ris, Bill Smith, Jim McLane, Ford Konno, Wayne Moore, and Clark Scholes.

*Backstroke.* Adolph Kiefer, who won his first national title in 1935 and was unbeaten in over 250 races in the next eight years, is the greatest of all backstroke stars. Other great American backstroke stylists are: J. H. Handy, Harry Hebner, H. Kruger, Wally Keloha, Albert Vande Weghe, George Kojac, Harry Holiday, Allen Stack, and Yoshinobu Oyokawa.

*Breast stroke.* Great American breast-stroke champions are: Michael McDermott, John Higgins, R. R. Hough, Bob Skelton, Jack Kasley, Joe Verdeur, and Jerry Holan.

EWING GALLOWAY

*The start of a swan dive*

*Women.* The first American woman to win international swimming honors was Ethelda Bleibtrey, the 100- and 300-meter free-style champion at the 1920 Olympics. Others who followed were: Ethel Lackie, Martha Norelius, Sybil Bauer, Helene Madison, Dorothy Burns, Agnes Geraghty, Eleanor Holm, Katherine Rawls, Gloria Callen, and Ann Curtis.

**Distance Swimming.** Long-distance swimming feats have helped to focus popular attention upon the sport. Capt. Matthew Webb, an Englishman who later died swimming the rapids below Niagara Falls, swam the English Channel on Aug. 24, 1875, the first person to do so. Since Webb, more than 50 persons have swum the Channel. The first woman to swim it was Gertrude Ederle, an American, who was the sixth person ever to swim the Channel and whose 1926 time broke all records up to that year. Florence Chadwick, another American, became in 1950 and 1951, the first woman to swim the Channel in both directions.

In 1940 John V. Sigmund of St. Louis swam 292 mi. nonstop in the Mississippi River in 89 hr., 42 min., the world's long-distance swimming record. Pedro A. Candioti of Argentina, another great distance swimmer, in 1935 swam 281 mi. nonstop down the Parana River in 84 hr.

**Development of Diving.** The development of competitive diving was an outgrowth of the upsurge of interest in swimming. It was early recognized that certain forms of plain diving are complementary to swimming and have definite uses, such as the ability to make a shallow or a deep plunge, to control the depth of the dive, and to level off into swimming position. The early history of competitive diving may be traced back to the seventeenth century, when formal gymnastics became popular in Germany and Sweden as a means of physical exercise and bodily development. Eventually, gymnasium apparatus was transferred to the beaches during the summer and gymnastics over water came into vogue. This was the beginning in Europe of fancy diving, which still may be considered as aerial acrobatics over the water.

*Olympic Events.* The first Olympiad at which fancy diving was included as an event was that held at St. Louis in 1904. High-tower diving was added four years later at London. As anticipated, Sweden and Germany dominated the early Olympic competition, although since 1920 the United States has won practically every diving event in both men's and women's divisions. In both springboard- and platform-diving events, the 1908 games provided that a certain number and type of dives be compulsory and that, in addition, a group of optional dives be performed.

Thereafter, additional dives were introduced and approved from year to year. These approved dives are arranged in six major classifications: (1) forward dives; (2) backward dives, the diver facing the board; (3) gainer dives, the diver facing the water but spinning backward; (4) cutaway dives, the diver facing the board but spinning forward after gaining distance by an outward spring; (5) twisting dives; (6) handstand dives, from the high tower or platform. M. P.

**SWINBURNE, ALGERNON CHARLES** [swɪ′nbərn; swɪ′nbɜrn] (1837-1909), English poet and man of letters, was born Apr. 5, 1837, in London, the eldest of the six children of Admiral Charles Henry and Lady Jane Swinburne. During his boyhood he lived chiefly at Bonchurch, on the Isle of Wight, and later attended Eton and Balliol College, Oxford, without graduating from either. In 1857, while still a student, he came under the spell of Dante Gabriel Rossetti, who dominated an admiring circle and who was then known chiefly as one of the Pre-Raphaelites. Swinburne's early work, much of it unpublished, indicates study and imitation not only of Rossetti and of William Morris, another friend, but also of older writers. His memory and his linguistic gifts, his diminutive figure and red hair, and, in general, his oddities of appearance and conduct soon drew curious attention to him. One observer's comment—"He's a cross between devil and the Duke of Argyll!"—is quoted by Henry Adams, who himself characterized Swinburne as "a crimson macaw."

After publishing an unnoticed volume of plays, *The Queen Mother and Rosamond* (1860), Swinburne won favor with a lyrical tragedy, *Atalanta in Calydon* (1865), modeled, like the later *Erechtheus* (1876), on the Greek drama. *Chastelard,*

*ALGERNON CHARLES SWINBURNE*

BROWN BROTHERS

also published in 1865, was the first of three dramas devoted to the romantic career of Mary Queen of Scots, *Bothwell* (1874) and *Mary Stuart* (1881) rounding out the trilogy. Though more successful than some of the later plays, *Chastelard,* like several others, would have seemed more at home in the Elizabethan than in the modern theatre.

The contemporary comments on *Chastelard* were by no means entirely friendly, but *Poems and Ballads* (1866), because of its pagan treatment of sex and religion, stirred up a veritable tempest. It is hardly too much to say that this book

affected the poet's reputation for a lifetime. Though the poems may not now seem shocking, Swinburne did offend in giving expression—partly disguised, to be sure—to his eccentric sexual sensibility. Readers are still impressed by the color and splendor of language, the imaginative power, and the sweeping rhythms of this volume, but most critics agree that *Songs before Sunrise* (1871) and *Poems and Ballads: Second Series* (1878) have greater merit. The former was dedicated to Giuseppe Mazzini and, like *A Song of Italy* (1867), was partly inspired by that Italian idealist, who was to rank with Walter Savage Landor and Victor Hugo in the poet's trinity of heroes. The book hails the liberation of Italy, envisions the ideal republic, and pays tribute to "the holy spirit of man" incarnate in successive generations and achieving progress in an atmosphere of freedom. Positivism and the theory of evolution contributed to Swinburne's philosophic outlook, but even readers unsympathetic with both must applaud the lofty ethics of *The Pilgrim*. In the second series of *Poems and Ballads,* such poems as *At a Month's End* and *Ave atque Vale,* the latter an elegy in honor of Charles Baudelaire, one of Swinburne's early masters in the art of poetry, are among their author's metrical triumphs.

After 1879 Swinburne lived in virtual retirement at The Pines, Putney, with Theodore Watts, later Watts-Dunton. Of his numerous later works, the two Arthurian poems, *Tristram of Lyonesse* (1882) and *The Tale of Balen* (1896), are especially notable. Some of his later literary ballads and poems honoring friends and little children are also pleasantly readable, but as the poet grew older and more conservative, critics complained, and not without reason, of his growing thinness of substance and lack of humanity.

Swinburne devoted much effort to literary controversy and criticism, the best of which includes *Essays and Studies* (1875) and *Miscellanies* (1886). Here, however, extravagant praise, violent invective, and some unfortunate tricks of style tend to obscure the critic's learning, fine taste, and genuine insight. Swinburne's most significant attainment was, however, his poetic craftsmanship, and upon his death on Apr. 10, 1909, his position among the great English lyric poets was secure. C. K. Hy.

**SWINDON,** a railway junction and municipal and parliamentary borough, in Wiltshire, England, situated about 77 mi. west of London. It is composed of the old town, said to have been founded by Sweyn I, father of Canute, and the new town, which grew up around the locomotive and car shops built on waste land. The two were combined when Swindon was incorporated in 1900. In addition to the railroad shops, electrical machinery and aircraft parts are manufactured. The town is a market center for the nearby agricultural districts. Pop. 1954, 68,850. A. W.

**SWINE,** a term used to designate all domestic animals commonly referred to as pigs and hogs. Zoologically, swine are classed as hoofed mammals of the family Suidae. They are stout-bodied, short-legged, artiodactyl animals with omnivorous habits. The meat of swine, known as pork, is in all forms an important part of the diet of people throughout the world.

## HISTORY

**Fossil History.** In all probability, man's first use of swine occurred during the Neolithic age, or before written history, when swine were found of the type known as turbary or Asiatic pigs. They were small, much valued for food, and were able to withstand winters because they existed on woodland diets. Chinese history relates that hogs were domesticated about 4900 B.C. Swine are mentioned in Biblical historical writings as early as 1500 B.C., while legendary and historical accounts mention the keeping of swine in Great Britain as early as 800 B.C.

Fossil remains of the ancestors of the present-day hog have been found in the Pliocene strata of Europe and Asia and in the Eocene strata of North America and Europe. Fossil remains of a prehistoric relative of modern pigs have been found in Nebraska. The domesticated hog of today is closely related to the wild hogs that are found in various parts of the world. These wild hogs are of various types, including the pigmy hog of Nepal, the bush pig of Africa, and the peccary of North America. There is reason to believe that the wild hog originally looked much like the domesticated hog of today. These early hogs were gregarious, forming large herds; muscular, with inferior meat; and fierce fighters, with large tusks. Young pigs were almost invariably striped with bands of dark brown on the body, much the same as young wild pigs are today.

**Origin of Domesticated Swine.** The domesticated hog appears to have had an origin that involves the crossing of several distinct species or races. Swine were domesticated in several regions of the world. Early explorers found domesticated hogs in the South Sea Islands. The domestication of hogs seems to have been universal, for nearly all countries possessed them and developed a characteristic type of hog.

Although the exact origin is obscure, it is generally accepted that the domestic hog of today descended from the European wild boar, *Sus scrofa,* and the first improvement was brought about by the Neapolitan, Siamese, and Chinese crosses (*Sus indica*). The scrofa, or wild boar, has been known in Europe, Africa, and Asia. Varieties existed on every continent except Australia and America. The wild boar is noted for its strength, vitality, vigor, activity, slow maturing, and long life. It has large, heavy shoulders, long head and snout, short back and loin, and long legs. The skin is thick, with long bristles. Prolificacy and apparent immunity to disease are outstanding features of this species.

The *Sus indica* is a wild, parental form of which little is known. This species includes swine of China, Japan, and eastern Asia. In general, it is small in size, short legged, early maturing, rapidly fattened, smooth coated, and quiet in disposition. This species, however, was not so prolific as the scrofa. The Chinese hog was predominantly white and black, or all white; the Siamese was black.

The Neapolitan, *Sus wadituaneus,* a breed from Italy, was introduced into England. It was of grayish-black color and was used to improve the English swine. The predominant colors of the modern English hog are white and black, no doubt influenced by the Chinese white hog and the black Neapolitan.

Present-day breeds vary in color and color patterns, size and general conformation, appearance of head and ears, prolificacy, early maturing, symmetry, feeding qualities, and quality of meat. Careful selection, feeding, and breeding have been the main contributions to the development of the modern swine. However, the domestic hog will revert to type if placed in a suitable environment. Large numbers of wild pigs are found in remote districts of the United States, Queensland, Wales, and New Zealand. In each case they have reverted from the domestic type. The so-called "razorback" is a typical example of this retrogression.

Leading swine countries are located in the Temperate Zone, even though swine were originally found in tropical countries. China has the largest population, but chiefly for domestic consumption. The leading countries in swine pro-

COURTESY OF THE U. S. DEPARTMENT OF AGRICULTURE

*A CHESTER WHITE BOAR*

COURTESY OF THE U. S. DEPARTMENT OF AGRICULTURE

*A YORKSHIRE SOW*

duction are: China, the United States, Brazil, the Netherlands, Germany, the U.S.S.R., France, Poland, Spain, Denmark, Canada, Argentina, England, Mexico, and Italy. The most important countries competing for world trade are Denmark, England, the United States, Germany, Poland, and the Netherlands.

**Swine in North America.** Columbus is credited with bringing hogs to North America. Spanish explorers brought them to Mexico, and Hernando De Soto is credited with introducing hogs into the United States.

The colonists settling along the eastern seaboard soon made pork production a source of income. As production exceeded domestic needs, pork and lard became available for export. The first recorded exports were to the West Indies in the year of 1790, and amounted to 6,000,000 lb. The Midwest expanded rapidly as a hog-growing area. Cincinnati developed into a large pork-packing center around 1840. Tennessee, Kentucky, and Ohio became the leading producers of swine. With the development of the railroads, and later of refrigeration, pork-producing areas moved farther westward into Illinois, Iowa, and Nebraska. After the Civil War (1870), exportation of lard and pork increased, and the larger population in the United States encouraged a steady increase in the production of pork until 1923. Since 1923 pork production has fluctuated, but the trend has been steadily upward, so that approximately 65,000,000 hogs were marketed in 1949. The corn belt produces 54 per cent, and the cotton belt approximately 22 per cent of the total population of hogs. The leading states in hog numbers are Iowa, Illinois, Indiana, Missouri, Ohio, Minnesota, Nebraska, Texas, Georgia, Wisconsin, North Carolina, Alabama, Tennessee, Kansas, and Mississippi.

Swine breeds raised in the United States are classified as follows: lard types—Berkshire, Chester White, Duroc-Jersey, Hampshire, Poland China, Spotted Poland China, Cheshire, Essex, Kentucky Red, Berkshire, Suffolk, and Victoria; bacon types—Yorkshire and Tamsworth.

The lard types of swine are developed in the United States to meet a need for the demand of lard. The breeds developed originated from stock imported from England, China, Spain, and Portugal. The bacon type of hogs are of English origin and are noted for their minimum production of fat to the maximum amount of lean meat. As the demand for lard decreased, both in the domestic and foreign trade, the lard hogs changed from overabundant producers of lard to types with a minimum amount, never, however, quite reaching the status of the true bacon hogs.

## HOG RAISING AND BREEDING

**Feeding.** The hog is distinctive in that the feeds used are largely concentrates. Pasture and roughages usually represent but a small portion of nutrient intake. The digestive tract of swine is simple and not adapted to the utilization of large quantities of fibrous material; therefore concentrates are deemed important. However, roughages and pasture help make the rations more economical and, in addition, supply the necessary minerals, vitamins, and proteins.

Corn is the basic feed for swine production. It is economical to produce and is high in carbohydrates. Other cereal grains and byproduct feeds can be used efficiently as the base

COURTESY OF THE U. S. DEPARTMENT OF AGRICULTURE

*A DUROC-JERSEY SOW*

COURTESY OF THE U. S. DEPARTMENT OF AGRICULTURE

*A POLAND-CHINA BOAR*

of a ration for swine. Corn alone cannot be fed economically to swine, for it is deficient in minerals and vitamins, and low in protein. High-protein supplements, such as meat scraps, fish meal, soybean meal, linseed meal, and tankage, are utilized with the corn. Alfalfa meal is a standard part of a ration for swine fed in drylot because it contains vitamin A and protein. Oats, wheat middlings, wheat bran, flour, and many other feeds are all utilized by swine.

Products from the dairies, such as whole milk, skim milk, buttermilk, and whey, sweet or sour, are excellent as part of a ration for swine. Root crops of various kinds, particularly cull potatoes which have been cooked, may be used.

G. W. V. N.

### WILD SWINE

Wild swine are various species of swine belonging to the genus *Sus*. All have a long, projecting snout, with the nostrils at the end, which is used for turning up the soil in search of roots. In body form, wild swine are heavy and massive; nearly naked, or only sparingly haired; and the ears are large and flapping. The upper canine teeth, especially in the males, are generally long, flattened, and slightly curved upward, thus forming offensive weapons. The feet are narrow and cloven. Although the European wild pig has become almost extinct, several species are found in India, Malaysia, and some of the East Indian islands, as well as in Africa. The Indian wild pig, *S. cristatus,* is of great size, while the pigmy hog, *S. salvanius,* of Bhutan, is scarcely larger than a rabbit. G. M. C.

**ŚWINOUJŚCIE** or **SWINEMÜNDE** [shvi′nɔu′ɛshtshɛ, svinəmü′ndə], a port and seaside resort, located about 300 mi. northwest of Warsaw at the extreme northwestern tip of Poland on the northern coast of Uznam Island, facing the Baltic Sea. It lies above the mouth of the Swine River, which is the 10-mi. long outlet of the Oder River. The city was founded in 1740 on the site of a former fishing village and was fortified in 1765. Close to the border of Germany, it is the outer port for the city of Szczecin (Stettin), and its harbor is protected by breakwaters, 2 mi. long. During World War II, Świnoujście was used by the Germans as an experimental rocket station and was heavily bombed a number of times. At the close of the war, it became a Polish city when the island of Uznam was assigned to Poland by the Potsdam Conference of 1945. Shipbuilding, lumbering, and furniture making are the chief occupational pursuits. Pop. 1946, 15,587. L. M. A.

**SWISS CHARD,** a variety of garden beet grown as a leafy vegetable. The fleshy leaf-stems may also be cooked in the same manner as asparagus. *See also* BEET; CHARD.

V. A. T.

**SWISSVALE,** an industrial borough in western Pennsylvania, in Allegheny Co., situated near the Monongahela River, 8 mi. southeast of Pittsburgh. It was incorporated as a borough in 1897. Transportation is furnished by the Pennsylvania Railroad. Manufactures include steel, chains and cables, switches and signals, glassware, forgings, alloys, and electrical equipment. Pop. 1950, 16,488.

**SWITCHGEAR, ELECTRICAL,** devices for making and breaking contact between the source of electric power and devices which utilize it. Many of the devices employed are automatic in character, being actuated by the current or voltage in the circuit itself. The devices used range from the simple switch to complex assemblies of switchboards and control equipment.

### SWITCHES

Electric switches are devices for closing and opening circuits, thus permitting current to flow or be interrupted, and for changing connections in circuits. They have a great variety of uses, the number of poles, type of contacts, number of breaks, and method of action and control being designed to fit the special needs of the service.

**Lighting Switches.** Switches for the operation of electric lights and various household appliances and small motors are made in a variety of forms, such as snap, rotary, tumbler, or push-button. These have a rapid make-or-break produced by a spring-and-cam mechanism. They are totally enclosed and have ratings from 5 to 30 amp., 125 and 250 volts, and are available in single-pole or double-pole and up to three-way or four-way circuits.

**Knife-Blade Switches.** Knife-blade switches are adapted to control of circuits of moderate-power capacity and low voltage. One or more copper blades are hinged between stationary terminals at one end, while the other end engages two or more stub members which are given a spring action, so that they press tightly against the blades and ensure a good contact. The stubs are connected to stationary terminals. The blades are swung by hand to engage or disengage. For the heavier currents, 400 amp. and above, the switches may be provided with silver-to-silver line-pressure contacts in order to give better sliding contact surfaces. They are available in single-pole, double-pole, triple-pole, and four-pole construction and may be of either single or double throw. The power ratings range all the way from 30 amp., 125 volts, d.-c. and a.-c., to 6,000 amperes, 600 volts, d.-c., and a.-c. Normally knife switches are mounted on insulating panels or switchboards.

For 600 volts and 200 amp. or more, the switches must be of the quick-break type, in which the movement of the contact blade is independent of the operator's control. This result is obtained by means of an auxiliary blade, fastened to the main blade by a hinge and spring and independent of the switch handle. When the main blade is withdrawn, the auxiliary blade stays closed until the spring tension snaps it open, thus securing a rapid break and reduced arcing.

**Disconnecting Switches.** Disconnecting switches, generally used on circuits above 750 volts, are heavy slot-blade devices, built like knife switches, which are used to isolate equipment and circuits from the voltage source so that these may be handled safely for inspection and repair. They are also used to transfer circuits, as, for example, from one bus to another, to a special test bus, or to a ground connection. They do not operate under load current but are opened only after a circuit breaker has interrupted the power current. They are made single-pole with single or double throw. Individual switches may be grouped together and be operated as a unit, e.g., three units for a three-phase circuit. Indoor units have current-carrying capacities of 400, 600, 1,200, 2,000, 3,000 and 4,000 amp. for voltages up to 23,000.

The switch must carry the maximum overload current of its circuit for one hour and up to 50 times its normal current rating for five seconds. The supporting insulators for indoor service should stand a voltage test of 2¼ times rated voltage plus 2,000 volts for one minute, and outdoor units, when wet, should stand a test of twice rated voltage plus 1,000 volts, by American Institute of Electrical Engineers (A.I.E.E.) standards. Because of the strong magnetic field in the switch when it is carrying heavy currents which might force the blade open, it is provided with a strong positive latch. This latch must be released when the wooden insulating pole, called a hookstick, is inserted in the eye of the latch to open the blade.

Outdoor units for sectionalizing high-voltage bus bars are provided with horn gaps so that the arc will rise on the horns from its own heat and will finally break when the arc length exceeds that which the voltage can maintain. They are also used to isolate circuit breakers and ground the transmission lines for test.

The smaller disconnecting switches, either single or in groups, are opened and closed manually, but motor or pneumatic control is generally used for heavy-duty and high-voltage units.

**Control Switches.** Control switches, usually drum or rotary type with multiple contacts, control from the switchboard (1) operating motors or solenoids for circuit breakers; (2) motor-operated governors on prime movers; (3) motor-operated rheostats to raise or lower generator voltage; and (4) other devices. The currents handled are small, ordinarily not more than 10 amp. If greater current is required in an operating solenoid or motor, an auxiliary relay is employed to link the control circuit through to the actual operating power supply. The contacts are insulated for 600 volts. For circuit-breaker control, they are associated with pilot lamps in the switchboard panel, which show red if the circuit is closed and under potential, but show green if the breaker is open, thereby providing an indication of the condition of the apparatus being controlled.

**Instrument Switches.** Instrument switches are similar to control switches but transfer the connections of the current and potential coil circuits of the various meters to other circuits. They are of the rotary type, with the cams closing silver-to-silver contacts, and are generally used in connection with a common ammeter, voltmeter, and synchroscope switched to different circuits.

## CONTACTOR

A contactor is a device for repeatedly establishing and interrupting an electric power circuit. It is actuated by other than manual means. Relays and contactors are alike in that each is an electric circuit switch actuated by an electromagnet or other power means ordinarily from a remote location.

**Construction.** A relay or contactor usually has a U-shaped magnetic frame of low-magnetic retentivity. A multiturn coil of copper wire is mounted on one leg of the U, and an armature is pivoted on the other leg in a position to extend across the open end of the U. Contacts are mounted on an extension of this armature. When current is made to flow in the coil, the armature is attracted to the frame and its contacts engage mating stationary contacts to establish an electric circuit. When the coil is de-energized, contacts separate as the armature moves away from the frame under the influence of gravity or springs. Mechanically operated contractors employ an armature moved by cams, cranks, or a fluid cylinder.

Relays or contactors have contacts proportioned to the current to be carried, ranging from 1/64 in. diameter, for a few milliamperes, up to compound contacts 2 or 3 in. wide carrying thousands of amperes.

Contact material for relays is usually silver, an alloy of gold, or other precious metal to provide current-capacity and corrosion-resistance as required by the relatively light contact pressures. For contactors, where ample pressure is available, contacts are often of copper, but the use of silver or silver-faced contacts reduces the size. A properly designed silver contact does not require filing or dressing.

A d.-c. relay or contactor has a magnet frame of soft iron or cold-rolled steel. To ensure that residual magnetism does not hold the armature when the coil is de-energized, the magnetic circuit includes a small permanent air gap, often formed by a nonmagnetic "residual" pin or stop that prevents the armature from touching the core of the magnet coil.

An a.-c. contactor has a magnet frame of laminated silicon alloy steel. Such a structure reduces effects due to the cyclic variation of the a.-c. flux, such as heating, and a noisy cyclic pull on the armature. To smooth this pull further, the armature and core face are made to meet accurately, and a lag loop or shading coil that embraces part of the magnetic circuit is provided in one face. This loop establishes a local flux of a time-phase different from the main flux, thereby eliminating periods of zero-pull on the armature.

**Magnetic Starters.** Magnetic starters are industrial control devices for starting and controlling electric motors by use of contactors and relays. A typical starter is a contactor with several contacts or poles, plus a protective overload relay. These poles close or open the motor supply circuit when the contactor is energized by way of a remote control. If excessive motor current flows, the overload relay contacts open the contactor coil circuit, which drops out the contactor to stop the motor.

For larger motors, the starters must limit current while the armature gains speed. For a.-c. motors, several contactors furnish successively increasing percentages of normal voltage to the motor from an autotransformer. For d.-c. motors, the starting current is limited by resistors which are cut out of the circuit by accelerating contactors, successively closed by various schemes.

**Solenoid and Plunger.** Straight line motion of considerable length is produced in many relays and contactors by an electromagnetic solenoid and plunger. The armature plunger moves within the solenoid, which is partially enclosed by an iron frame to form an efficient magnetic circuit. This frame is solid for d.-c. use and laminated for a.-c. Contacts mounted on an extension of the plunger engage fixed contacts and form an efficient, simple device without pivots or hinges.

**Blowout.** The blowout is a magnetic device to assist in breaking the arc formed when contactor contacts are opened. It has a coil with magnetic core and side plates so disposed that a magnetic field is produced in a direction transverse to the arc stream. It is particularly useful in d.-c. circuits where there is no natural "current zero" and an arc between the contacts may persist. Reaction between the blowout field and the magnetic field of the arc forces the arc away from the contacts, eventually breaking it by attenuation. The blowout coil is usually in series with the contactor and, therefore, has a blowout effect proportional to the current being interrupted.

## CIRCUIT BREAKERS

A circuit breaker has been defined as a device for interrupting a circuit between separable contacts under normal or abnormal conditions (A.I.E.E. standards). A movable contact operates under the pressure of a lever or gear mechanism to make or break contact between two stationary terminals mounted on a base. Large breakers are operated by motor or solenoid. The interruption may be accomplished in air or in oil. The responsibility placed upon the breakers is ever increasing because of the constant growth in size of modern power systems, and the absolute dependence on the breakers to open the circuits when necessary to protect apparatus or to maintain continuity of service in the major portions of the power system.

**Air Circuit Breakers.** Air circuit breakers, manually or electrically operated, are available up to 750 volts and in a wide range of ampere capacities, even up into the thousands, and are built for one, two, three, or four poles. By the addi-

tion of appropriate relays that control the tripping of the breaker, protection can be provided against excessive or reverse currents, undervoltage, overvoltage, or unbalanced voltage and phase reversal. Under these controls, the tripping may be arranged as instantaneous or with "inverse time"; in the latter, the heavier the overload current, the faster the breaker will open. Different designs use a variety of elements in association with the final break of the arc so as to avoid roughening or pitting of the main copper contacts, which open first. Thus, in the more common breakers, auxiliary contacts of carbon blocks may take the arcing, but a magnetic blowout is provided for street railway service. They are used to control the circuits for lighting, power and motors, d.-c. and a.-c., and for d.-c. railway circuits for even higher potentials.

**Air-Blast Breaker.** The air-blast breaker has been developed to replace the oil circuit breaker to eliminate the danger of explosion and fire incident to the presence of oil. It uses the prestored energy of compressed air of 135 to 215 lb. per square inch for both breaker operation and circuit interruption, keeping the arcing time practically constant at ½ cycle (1/20 sec.) or less. As the moving contact draws out the arc, an air blast of high velocity, either axial or crosswise, is shot through the arc stream, cooling and quenching the arc at an early current zero.

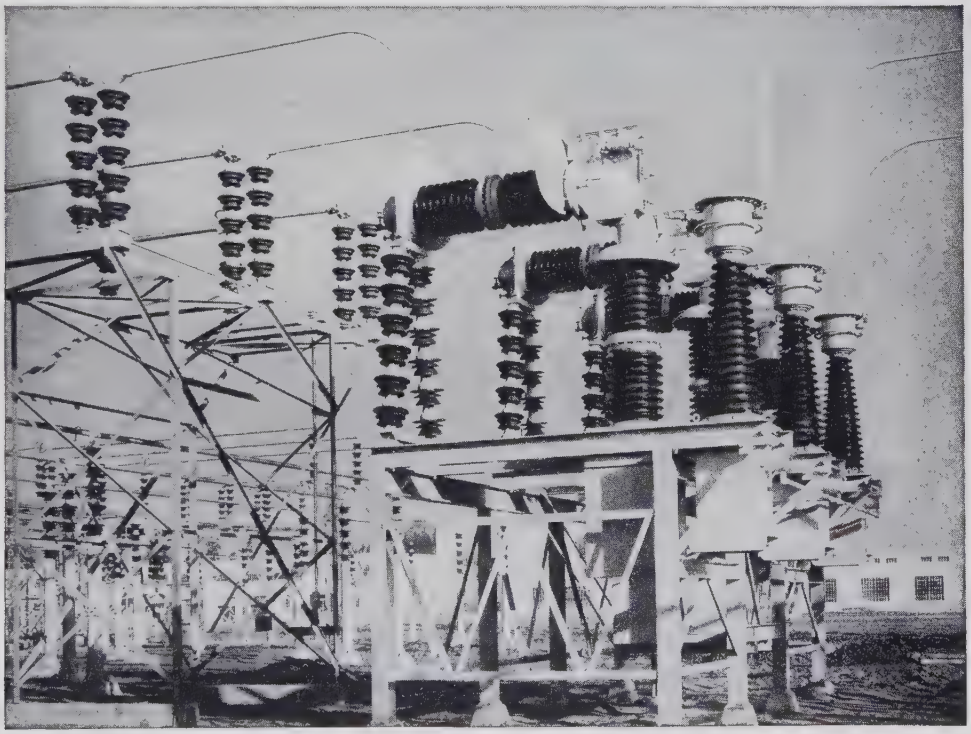
**High-Speed Air Breaker.** The high-speed air breaker is used in industrial service with heavy loads. It is also useful in electric railway service, at 1,200 volts and above, where operating times of from 0.08 to 0.15 sec. are required in order to prevent the flashover of generators or synchronous converters on short circuit. This rapid action is obtained by eliminating the mechanical latch, which holds the ordinary breaker closed, and using instead a magnetic field and an armature on the pivoted lever to hold against a spring tension. The design is such that at excessive current, and with a special bucking bar, the holding field is canceled and the breaker flies open under the pull of the spring. Instead of interrupting the main power flow, the opening of the breaker places a resistor in the circuit and thus limits the machine current to a safe value.

**Deion Circuit Breaker.** The deion circuit breaker is an oilless breaker developed for 15 kv. and 500,000 kv.-a. interrupting capacity in the early application of the multiple cold-cathode principle of Dr. J. Slepian. Later developments have brought forward self-contained air-circuit breakers in successive ratings down to 100,000 kv.-a. at 2.5 and 5 kv. The deion breaker consists of a stack of copper plates each 1/16 in. thick and separated by 1/16 inch from the other. When an arc is drawn between the contacts under the plates, it is blown by a magnetic field into the plates, where it is broken up into a series of arcs each 1/16 in. long. Thus, in every inch of plate structure, each of 8 cathodes has its immediately adjacent, rapidly deionizing gas layer. Instantly after the current passes through zero in its normal cycle, each cathode layer is deionized, rendering it nonconducting. It can withstand 250 volts faster than any practical power circuit can supply it. To reignite the arcs after current zero takes 8 times 250, or 2,000 peak volts per inch of structure.

As a result of research and development to improve interrupting principles, magnetic air breakers are available in which the interrupting capacity in a given space has been more than tripled. The short arc chute, 19 in. long for a 500,000-kv.-a., 15-kv. unit, has made it adaptable to the compact, horizontal drawout construction.

**Oil Circuit Breaker.** The oil circuit breaker long has been standard to open large amounts of a.-c. power and to control high-voltage a.-c. circuits. It can interrupt many more volts per unit length in the oil than in the open air because drops of oil act as deionizing centers in the arc space. These centers consist of relatively cool un-ionized gas, which comes from the decomposition of the oil and mixes turbulently into the arc space. The oil circuit breaker interrupts the a. c. wave at zero value, at which instant the magnetically stored energy of the system is a minimum, an important feature in reducing the surges in connected circuits.

Physically, oil breakers embody the desirable construction



*IMPULSE OIL CIRCUIT BREAKER RATED AT 230,000 VOLTS, 600 AMPERES*

COURTESY OF GENERAL ELECTRIC CO.

features of heavy welded-steel tanks and strong supports for the terminals, necessary to handle the explosive nature of the power interruption. They are available up to 287 kv. with interrupting capacities as great as 3,500,000 kv.-a. High-speed breakers can operate in 3 cycles (1/20 sec.).

The following are typical of the special devices that have been developed to control the arc for heavy power circuits:

*(a)* Addition of oil blast explosion chambers to the stationary contacts of the breaker, where the gas pressure generated by the arc forces oil between the contacts.

*(b)* Use of an increased number of interrupters up to six breaks per terminal for high voltages where the arcs decompose oil into gas which, in turn, creates pressure and forces oil through the ports and between the contacts.

*(c)* Use of the impulse oil circuit breaker for 287 kv., constructed so that each phase has two horizontal herkolite cylinders inside an oil-filled porcelain housing. Eight breaks per phase are employed with compressed springs releasing a force of 24,000 lb. in 0.01 sec. to force oil across each arc path.

*(d)* Addition of deion grids to the contacts, the grid holding the arc in a groove by its magnetic field and forcing it against a solid wall of oil. This arrangement gives a high rate of decomposition of the oil and so supplies continuously fresh un-ionized gas, which is forced through the arc stream to dilute it.

### FUSES

The electric fuse is a protective device housing a metallic link of certain critical dimensions giving it definite current-carrying capacity. When this current is exceeded, the link melts or fuses and thus opens the circuit. Fuses are generally rated on the basis of a room temperature of 75° F.

**Plug.** The household plug fuse with a screw base uses a fusible alloy, ordinarily visible through a mica cover, as its link. This type is limited to 125-volt circuits with 15 amp. on the branch circuits and 30 amp. on the main supply.

**Cartridge.** In cartridge fuses, the link is enclosed within a fiber tube surrounded by a powdered material that excludes air and interrupts the arc when the fuse blows. The ends of the link connect to knife-blade or cylindrical terminals on the cartridge, which make contact when inserted between the mounted clips to complete the circuit. These fuses are rated from 1 to 600 amp. for 250-volt and 600-volt service. In renewable types, a new link can be inserted after one has blown.

**Expulsion.** Expulsion fuses are made to open short circuits on potential and power circuits, both indoor and outdoor. Indoor capacities are as great as 80 amp. and 23 kv.; outdoor capacities, 200 amp. and 115 kv. As the name implies, the fuse is so designed that the expulsion of the metallic vapor extinguishes the arc formed by the blowing of the fuse.

**Oil-immersed.** Oil-immersed fuses enclosed in a strong housing gain the advantage of quenching the arc under oil when the fuse blows. Used as cutouts, they protect primary supply to feeders and branch circuits both in overhead and underground installations. They can handle up to 300 amp. and 15 kv.

### RELAYS

A relay is a device that is operative by a variation in the conditions of one electric circuit to effect the operation of other devices in the same or another electric circuit (A.I.E.E. standards). It is a combination electrical-mechanical device in which a coil, or coils, in an electric circuit will cause a moving element to travel and produce operations, generally in other circuits. Relays, as a class, have an enormous number of functions to perform so that mention of the functions is necessary to specify more particularly the purpose of any specific device.

**Telephone Relays.** Multiple contact telephone relays are an essential element of automatic dialing equipment, some 50,000 being required in a 10,000 line dial exchange. The relays comprise small electromagnets which, when current flows in the exciting coil and magnetizes the core, close twin contacts of palladium, 1/16 in. long, and so pass the current on to the next relay. Thus, in mechanically switching a call through to its destination, relay after relay will close and remain closed until the call is completed. When the subscriber hangs up, the current is interrupted and all relays open by spring action.

**Magnetic Relays.** Magnetic relays, or electromagnets, may be used to open or close automatically the contacts of an electric circuit upon overcurrent or undercurrent in the circuit, or upon overvoltage or undervoltage. In the overcurrent relay, the current flowing through the windings of the coil furnishes the magnetic flux to open the contacts, the pull being balanced against a spring. In the undercurrent relay, the coil is shunt-wound instead of series-wound.

**Protective Relays.** The protective relay is an electrical-mechanical device installed to detect some particular abnormality in the circuit which it guards. When the abnormality appears, the relay causes the appropriate circuit breaker to open and protect the circuit or equipment. It is expected to isolate faulty lines and apparatus automatically from the remainder of the system. The coil, or coils, connected to the circuit are affected by what takes place there and the movable part travels under control of the coil to close a contact device. This last element completes the tripping circuit of one or more breakers.

**High-Speed Relays.** High-speed relays closing in ½ cycle have been developed for use in connection with high-speed circuit breakers working in 3, 5, or 8 cycles. Rapid clearing of the fault prevents burning down the conductors, breaking the insulators, and losing synchronism between the ends of the transmission line.

### SWITCHBOARDS

The switchboard is the control and operating center for the electric power plant. Usually its design is based on the one-line diagram of main connections that shows the generators involved, how many circuits are to be fed, and all special interlocks, relays, and alarm provisions.

For power stations and stations of small capacity, direct current and alternating current up to 2.5 kv., the circuit breakers and bus bars formerly were mounted directly on the board or adjacent to it, so that the switchboard was the actual operating unit. In larger stations, these elements are located at some distance from the board in a bus room or on a switching mat, and the switchboard is the control center.

The switchboard panels for small d.-c. units, one or two machines at 250 volts, generally carry air circuit breakers, manually operated knife switches, a voltmeter with transfer switch, an ammeter, a watt-hour meter, a field ammeter, ground lamps, and a rheostat for each generator. Switches with fuses on subpanels control and protect the feeder circuits.

A. H. L. and R. A. A.

**SWITCH GRASS,** a vigorous perennial, *Panicum virgatum,* having erect stems 3 to 6 ft. tall, growing from creeping rootstocks in dense clumps and bearing long, flat, taper-pointed leaves. The large, spreading, flowering panicle is sometimes 20 in. in length, and the plant is sparingly grown as an ornamental. It is native to the eastern half of the United States and southward to the West Indies; it forms a constituent of prairie hay in parts of the United States.

**SWITHIN, ST.** [swɪ′thɪn] (died 862), counselor of Egbert, king of the West Saxons, and made bishop of Winchester in 852, was famed for humility and charity to the poor. He was patron saint of Winchester Cathedral from 984 until 1538, when his shrine was destroyed and his relics scattered. His feast is July 15, St. Swithin's Day. W. C.

**SWITZERLAND.** The Swiss Confederation is a federal republic composed of twenty-two cantons. The name Swiss Confederation was first used in the Priest's Charter of 1370. The present constitution, formulated and adopted in 1874, legally established the name *La Confédération Suisse*. Switzerland is situated in central Europe between the northern latitudes of 47° 48′ 36″ and 45° 49′ 09″ and the eastern longitudes of 5° 57′ 23″ and 10° 29′ 34″. The total area of the country is 15,940 sq. mi., or just over twice the size of New Jersey. It is bordered on the north by Germany, on the west by France, on the south by Italy, and on the east by Austria and Liechtenstein. Lake Constance and the Rhine River form part of the northern frontier; the Jura Mountains form part of the western boundary; Lake of Geneva and the Italian Alps form part of the southern frontier. The Rhine, turning south from Lake Constance, forms part of the eastern boundary. Three of the Swiss cantons are divided into demicantons, as follows: Appenzell into Appenzell Ausser Rhoden (Appenzell A. Rh.) and Appenzell Inner Rhoden (Appenzell I. Rh.); Basel into Basel-Land and Basel Stadt; and Unterwalden into Nidwalden and Obwalden.

## GEOGRAPHIC FEATURES

**Topography.** Switzerland is an *El Dorado* for the geologist. The folded Jura Mountains of classical structure, the once-glaciated Swiss Plateau with its moraines, Drumlins, and eskers, and above all the geologically complex Alps, with their sheetfolding structure, give a variety nowhere equalled in such a small area. Switzerland can be divided easily into three natural regions: the Jura Mountains, the Swiss Plateau, and the Alps. The Jura form the boundary zone between Switzerland and France, extending from Geneva (Genève) to Basel and Schaffhausen. They consist of regular limestone folds, similar to those of the Appalachians, and result in longitudinal valleys, long-stretched ranges, and narrow gaps giving outlet for the rivers through the ranges. Only the valleys can be used for cultivation; the ranges themselves are forest covered or have pastures. The density of population is low. The Swiss Plateau is actually a basin between the Jura and the Alps, filled with glacial material dating from the Ice Age and now eroded by the many rivers. Its surface is rolling, with broad cultivated valleys and wooded divides. Here live the bulk of the Swiss population; here are the real crop fields and pastures and the larger cities; here also is the industrial development for which Switzerland is so well known. The Alps comprise roughly the southern half of Switzerland. High, snow-covered mountain massifs are separated by deeply eroded valleys. In the chief valleys the broad river bottoms are used for cultivation. The slopes leading up to the Alpine meadows are forested. The population is sparse, but the Alps are a major source of income because of the beauty of their scenery and the attraction of the high mountains for the mountaineers. Tourists flock to them in summer and in winter. Resorts are found everywhere.

*Rivers and Lakes.* Most of Switzerland belongs to the Rhine system, especially to the Aare, a tributary of the Rhine which combines the many rivers of the Swiss Plateau, such as the Reuss and the Limmat. Outside of the Rhine drainage system are the Rhône in the southwest; the Ticino, a tributary of the Po, in the south; and the Inn, a tributary of the Danube, in the east. None of the latter rivers has any value to the Swiss from the point of view of transportation. The Rhine becomes navigable at Basel, just inside the Swiss boundary. Switzerland is famous for its lakes, and practically all of them are of glacial origin, dating from the time when large glaciers poured out of the mountains, invading the surrounding territory. The largest lakes are scattered across the country from southwest to northeast: Lake of Geneva, Lake of Neuchâtel, Lake of Bienne, Lake of Thun, Lake of Brienz, Lake of Luzern, Lake of Zug, Lake of Zürich, Lake Wallen and Lake Constance. In the south, in Ticino Canton, are Lake Lugano and Lake Maggiore. The beauty of these lakes, with their vivid color and mountain setting, has been a great asset to the Swiss tourist industry.

**Climate.** Mountainous Switzerland has marked climatic variations, influenced both by the altitude of the different regions and by their exposure to the prevailing winds and the sun. Temperatures in the lower valleys average between 50° and 60° F. annually, but in summer they rise to 86° or more. July is the hottest month, January the coldest.

In the Alps, perpetual snow covers the highest peaks, the snow line ranging from about 9,000 ft. on the western heights to 10,500 ft. on the eastern mountains. Winter temperatures are below freezing throughout the country except for the north shore of the Lake of Geneva and of the Swiss-Italian lakes, areas protected from the cold north wind, known as the *bise,* and having a mild climate like that of northern Italy. During January and February high-pressure conditions over the Alps bring the clear, cold weather best suited to winter sports, for which Switzerland is noted. The southern

*THE AARE RIVER AT BERN, SWITZERLAND*

COURTESY OF THE SWISS NATIONAL TOURIST OFFICE

slopes benefit from the direct rays of the sun and are much warmer than the northward-facing slopes.

Sudden violent storms, with rain or snow, are numerous in Switzerland. In the spring, summer, and fall, the prevailing wind is the *föhn,* a warm, dry wind blowing from the east and southeast. Because the moisture-laden winds from the Mediterranean encounter the barrier of the Alpine ranges, the southward-facing slopes receive nearly twice as much rainfall as those facing north. Most of the winter precipitation is in the form of snow, the accumulation in the valleys averaging from 20 to 25 ft. in depth and in the high mountains from 45 ft. upwards. The average annual precipitation at Basel (910 ft.) is 32.5 in.; at Lausanne (1,220 ft.), 46.3 in.; and at Bevers (5,620 ft.), near St. Moritz, 32.5 in.

**Soils.** Soils are generally leached and poor. They are stony on the mountain slopes, but fertilizers are used on the better ground to make higher production possible. Three-fourths of the Swiss area is productive, about one-third of which is forest and the rest crop land and pasture.

**Flora and Fauna.** The flora varies according to climate and altitude. The Swiss Plateau is still part of the central European oak and beech zone, although those trees are often intermixed with pines. On the south slope of the Alps the chestnut is the most typical tree. High on the slopes conifers prevail more and more, forming a transition zone between the deciduous trees and the Alpine meadows on high elevations. Characteristic of the mountains are the very colorful flowers, starting with the crocus and narcissus in the spring and culminating with a profusion of types, among which are the Alpine roses, the saxifrages, the various gentians, and the rare edelweiss. Wild animal life has been greatly reduced by man; while the Alpine partridge and the mountain hare abound, the deer, the marmot, and the chamois, which inhabit the higher Alpine regions, are less common. Much is being done to preserve remnants of former fauna. In the Swiss National Park, near the Austrian border, there are, in addition to deer and chamois, still a few ibex and foxes, as well as white snow grouse and eagles. S. VanV.

## ETHNOLOGY AND POPULATION

**Racial Origins.** The racial origins of most of the population are Roman and German. The country was occupied successively by the Helvetians, Romans, Alamanni, Burgundians, and Franks. Racially the Swiss approach the Alpine type; they are rather short and stocky, with brown hair and dark or grayish eyes. However, there has been a strong influx of the fair Nordic type. While the Swiss are a unit nationally, there are four different ethnographic groups: the German Swiss, the French Swiss, the Italian Swiss, and the Rhaeto-Roman Swiss. Each speaks its own language. There is also a large foreign element in Switzerland; some foreigners have been attracted by the peace and beauty of the country, while others are political refugees. The foreign population varies, but generally totals about 400,000.

**Language.** On the basis of spoken language the population was distributed in 1941 as follows: German 3,097,060; French, 884,669; Italian, 220,530; Romansh (a Rhaeto-Romanic dialect of Indo-European derivation, spoken in Grau-

bünden), 46,456; others, 16,990. The five French-speaking cantons (Fribourg, Vaud, Valais, Neuchâtel, Geneva) are in the western part of the country along the French border. Ticino, the lone Italian-speaking canton, is on the Italian border. In the remaining cantons German is the dominant language.

**Religion.** The Protestants form a majority in the country, although there are many Roman Catholics. In 1941 the communicants of the various faiths numbered as follows: Protestants, 2,457,242; Catholics, 1,724,205; Jews, 19,429; others, 34,828. Of the five French-speaking cantons, Valais and Fribourg are the only ones in which Catholics outnumber Protestants. Ticino, the Italian-speaking canton, is overwhelmingly Catholic. Romansh-speaking Graubünden is almost evenly divided. The strongest Protestant cantons are Zürich, Bern, Glarus, Basel, Appenzell A. Rh., Schaffhausen, Thurgau, Vaud, and Neuchâtel. The strongest Catholic cantons are Luzern, Uri, Schwyz, Unterwalden, Zug, Fribourg, Appenzell I. Rh., Ticino, and Valais. Most of the Jews live in Basel, Zürich, and Geneva.

**Occupations.** In 1941 the cities of 10,000 inhabitants or over contained a total of 1,402,335 individuals, while cities of under 10,000 inhabitants, plus the definitely rural population, totaled 2,863,368 individuals. By this standard, most of the Swiss live in the country or the small towns. It does not mean, however, that most of the population is engaged in agricultural pursuits, since industry in Switzerland is quite decentralized. According to the Swiss Federal Bureau of Statistics, of every 1,000 Swiss inhabitants earning a livelihood in 1941, 208 worked in agriculture and forestry, 435 worked in industry, and 100 worked in commerce, banking, and insurance. In only three cantons, Fribourg, Graubünden, and Valais, and two demicantons, Obwalden and Appenzell I. Rh., did the number engaged in agriculture exceed the number engaged in industry. By this same standard the most industrialized cantons were Zürich, Uri, Glarus, Zug, Solothurn, Basel (both Land and Stadt), Schaffhausen, St. Gallen, Aargau, Thurgau, and Neuchâtel. In the demicanton of Appenzell A. Rh., 489 per 1,000 inhabitants were engaged in industry.

**Population.** Official statistics placed the population of Switzerland in 1941 at 4,265,703; the official estimate for 1946 gave 4,506,000. According to the latter date, the five largest cities are: Zürich, 366,752; Basel, 172,837; Bern, the capital, 137,816; Geneva, 139,735; and Lausanne, 99,372.

## GOVERNMENT AND POLITICS

**Central Government.** The Constitution of 1874, plus numerous amendments up to September 1950, form the basis of the present government. The government is a federal republic with sovereignty residing in the people and in the various cantons. The powers of the federal government are exercised through a two-chamber legislature, an executive council responsible to the legislature, and a federal tribunal. The legislature (Federal Assembly) is composed of the National Council, elected on the basis of population (roughly one representative for every 22,000 citizens), and the Council of States, which represents the cantons (two representatives for each canton, or forty-four in all). Universal suffrage prevails in the choosing of the electoral colleges in the cantons, which in turn choose the members of the National Council. The principle of proportional representation operates in the distribution of seats to the parties by these electoral colleges. The members of the Council of States are chosen by the diets of the respective cantons. The executive power resides in the Federal Council, which is composed of seven members chosen by the Federal Assembly from all citizens eligible to the National Council. The Federal Council is responsible to the Federal Assembly, and because of this the Swiss government is essentially more akin to the British form of government than it is to the American form, to which it bears a similarity in the matter of federalism. The Federal Tribunal is selected, like the Federal Council, by the Federal Assembly; it exercises not only the usual

trial powers of such a court but also wide interpretative powers, defining the powers of the federal government, arbitrating between the cantons, and safeguarding the residual powers of both the people and the cantons from encroachment by the federal government. The policies of the government are subject to ultimate review by the people through the initiative and referendum, possibly the best-known contributions of the Swiss to the advancement of popular government.

*Federal Powers.* By the Constitution of 1874 the government of the confederation was given considerable powers, such as sole power to declare war and make peace and to conclude treaties of alliances; the power to train, equip, and direct the military forces and even recruit forces directly in time of emergency; and the power to levy import taxes and to regulate the foreign trade. The federal government has complete control over forests, fish and game, railroads, money, weights and measures, marriage and divorce, posts and telegraph, higher education, and hours and conditions of labor. It also has the right to legislate for the control of communicable diseases and in certain categories of commercial, civil, and penal law. The federal government also undertakes to guarantee civil liberties to all Swiss citizens. The amendments to the constitution since 1874 have given the federal government power over all hydraulic resources, air navigation, manufacture of armaments, essential highways, and other matters of federal concern.

**Political Parties.** General elections are held in Switzerland every four years. In the elections of 1947 the preponderance of center and right parties was continued. Representation in the National Council was as follows: Radicals (a liberal party), 52 seats; Social Democrats, 48; Catholic Conservatives, 44; Peasant Party, 21; Landesring and Liberal Socialist Party, 9; Liberals, 7; Communists, 7; Democrats, 5; and independents, 1. For the Council of States the representation was: Catholic Conservatives, 18; Radicals, 11; Socialists, 5; Peasant Party, 4; Liberals, 2; Democrats, 2; and independents, 2.

**Finance.** During World War II the budget showed a deficit of about one billion francs each year, but in 1946 the tide turned and in 1947 receipts totaled 2,154,430,000 francs and disbursements 1,933,461,000. The total debt of Switzerland at the end of 1948 was nearly eight billion francs.

**Armed Forces.** Military service in the national militia is compulsory and universal, with varying periods of service required after initial training. Fully mobilized, Switzerland's armed forces total 720,000, including 270,000 men and women in the auxiliary services. Much of the defense of the country has been based on fortifications guarding the key mountain passes. In 1949 there was an air force of 25 squadrons and 500 fighter planes.

## ECONOMIC ACTIVITIES

**Industry.** Switzerland is a highly industrialized country. Before World War II the production of textiles, machines, watches, watch parts, jewelry, wood products, foodstuffs, and tobacco, along with the construction industry, absorbed most of the industrial energy of the people. Also important are the paper, leather, rubber, graphic art, and chemical industries. World War II dislocated Swiss industry; the chemical, metal, and machine industries were greatly expanded at the expense of certain textile industries. Since the war these industries have been reverting to their prewar ratios. The increased use of machinery and electric power has contributed toward decentralization of industry, which fits well the over-all economic picture of the country and particularly its agricultural pattern, which is characterized by small farms specializing in products for local consumption. The Swiss export large quantities of heavy machinery, such as turbines, locomotives, and diesel engines. They are widely known for their production of machine tools and precision instruments. They produce, in addition, a variety of military supplies and equipment.

**Commerce.** Switzerland has a highly developed foreign trade. Since it was surrounded by the Axis armies in World War II, there was naturally a precipitate decline of British, French, and American trade with Switzerland and a great increase of German and Italian trade. Trade also increased with the Axis satellites, as well as with such neutrals as Sweden, Spain, and Argentina. Since World War II the Swiss have continued to maintain sizable trade relations with the Balkan and central European countries. There have been indications that the U.S.S.R. is anxious to improve its trade relations with Switzerland. At the end of World War II the Swiss imports and exports were far below their normal prewar level. Since then Switzerland has concluded important trade agreements. In general, with expansion of trade since the war, there has been an excess of imports over exports; imports totaled 4,998,900,000 francs in 1948, and exports 3,434,500,000. Nearly one-third of the imports came from the United States, followed by France, the United Kingdom, Italy, Argentina, Germany, and Sweden; the United States took the greatest share of Swiss exports, and France, Sweden, Italy, Argentina, and the United Kingdom, in that order, a smaller share.

**Agriculture.** The agricultural resources of the country do not allow for complete self-sufficiency. Wheat and cereals must be imported. However, some fruit and dairy products are available for export. In 1945 the cantons with the greatest amount of land under cultivation ranked in the following order: Bern, Vaud, Zürich, Fribourg, Aargau. Those with the least land under cultivation were Uri, Glarus, Unter-

walden, and Appenzell. The total of hectares under cultivation (one hectare equaling 2.47 acres) has increased from 191,668 in 1917 to 335,292 in 1945. Most sheep and goats are produced in the canton of Graubünden. The cantons which led in the production of cattle were Bern, Zürich, Luzern, Fribourg, St. Gallen, and Vaud. The timber industry is sufficient to meet the local needs.

*A shepherd bringing home his flock passes an old château in the Tarasp-Schuls-Vulpera region of the lower Engadine, one of the most picturesque regions of Switzerland.*

COURTESY OF THE SWISS NATIONAL TOURIST OFFICE

**Mining.** Despite its mountainous terrain, Switzerland is not rich in minerals, and hence mining is not too prominent in the economy. Salt is mined in two districts, Bex and the area of Schweizerhalle, Rheinfelden, and Ryburg. The cantons in both cases hold a monopoly. However, at Bex the canton of Vaud has leased the mines to a private company, while in the other district the cantons themselves work the mines through a joint stock company. The two chief iron mines in the country are the Fricktal Mines in the canton of Aargau and the Gonzen Mines, near Sargans. In 1937 Switzerland exported 148,580 tons of iron ore, 17,180 tons of copper, and 27,310 metric tons of aluminum and aluminum products. In recent years extensive geological surveys have been made to ascertain the oil resources of the country. As a result, a small quantity of oil is now being produced by a few wells in the canton of Vaud.

**Transportation and Communications.** The Swiss have a well-developed system of railroads. In 1947 the total length, normal and narrow gauge, was 3,245 mi., of which 1,708 mi. were electrified. All the main trunk lines are owned and operated by the federal government. The system connects all principal cities. Motorized transport and airlines supplement the railways. There were in 1950 some 10,000 mi. of good highways. There is considerable transport by water, especially on the Rhine River. Basel has developed into one of the major inland ports in Europe. The government owns and operates all telephone and telegraph lines and Radio Suisse.

**Money and Banking.** Economic and political stability has enabled Switzerland to develop one of the most advanced banking systems in the world, far disproportionate to the country's size. Foreign funds have flown in a steady stream into Switzerland, seeking safety in a war-torn and politically unstable world. The banking system can be divided into the state system and the private system, although the tendency has been for the state system to absorb the private. The state system centers around the Swiss National Bank and the cantonal banks. The Swiss National Bank started operations June 20, 1907. It has the exclusive right to issue paper money, and is a stock company in which the cantons hold shares but the federal government does not; however, the latter has power to control the bank. It establishes the amount of metallic reserve that the bank must

*The entrance to the Simplon railway tunnel, 12¼ miles long, at Brig*

COURTESY OF THE SWISS NATIONAL TOURIST OFFICE

maintain and may change the reserve ratio when it so desires. It performs the usual central bank services for the government. The cantonal banks supplement the functions of the central bank. The private banking system centers around a few great commercial banks, which in 1926 were eight in number and were members of the Cartel des Banques Suisses. At that time their paid-in capital stock was one-fourth that of all the banks. The country's monetary unit is the Swiss franc, worth about 23½ cents in United States money.

**Labor.** The chief trade union federation in Switzerland is the Union Syndicale Suisse. Its total membership was 312,935 in 1945. It contained most organized workers, but there are a number of other labor organizations, some of them with marked religious leanings. More akin to the Union Syndicale Suisse, in that the federative principle is employed, is the Federative Union of Personnel of Administrations and Public Enterprises, which is composed of unions of workers in various branches of the federal government, especially the munitions industries, the postal services, the railways, and the central administrative offices. Some of the member unions of this federative organization are also attached to the Union Syndicale Suisse, such as the railroad, public service, telephone and telegraph, munitions, and postal workers. The membership of the Federative Union of Personnel of Administrations and Public Enterprises was 84,541 in 1945. The Federation of Swiss Societies of Employees is the third large federative organization. In 1945 it was composed of seven unions, of which workers in retail establishments formed the largest union, and had a total membership of 71,983. The various cantons have conciliation committees to settle trade disputes. In 1945, out of 354 cases submitted to these boards, 313 were settled.

## SOCIAL AND CULTURAL ACTIVITIES

**Cultural Development.** Switzerland has a rich cultural heritage. It has produced many outstanding men of art, literature, and science. Both Nikolaus Manuel (1484-1530) and Hans Holbein the Younger (c.1497-1543), the gifted Renaissance artists, were Swiss, and so was the physician Paracelsus (c.1493-1541), sometimes considered the first modern scientist. Nicholas of Flüe (1417-1487), a theologian, achieved wide recognition and was canonized in recent years. Huldreich Zwingli (1484-1531) and John Calvin (1509-1564), great religious reformers, are claimed by the Swiss. Swiss artists of repute include Heinrich Füssli (1742-1825) and Ferdinand Hodler (1853-1918).

*Literature.* Though small in size, Switzerland has a great literary tradition. Johann Bodmer (1698-1783) and Johann Breitinger (1701-1776) exerted influence on German literature. Mme. de Staël (1766-1817) was of Swiss parentage. The Swiss are also proud of their outstanding educator, Heinrich Pestalozzi (1746-1827). Other well-known Swiss writers are Jeremias Gotthelf, Gottfried Keller, Conrad Ferdinand Meyer, Rodolphe Töpffer, and Carl Spitteler. Among contemporary writers Hermann Hesse, novelist, Karl Barth, Protestant theologian, and the novelist C. F. Ramuz are probably best known. The people of Ticino have produced a somewhat provincial literature. Their outstanding present-day writer is Francesco Chiesa. Among the Romansh, Peider Lansel is the foremost poet. Two Swiss historical writers are outstanding: Jakob Burckhard, author of a classical history of the Renaissance, and Johannes von Müller, author of *The History of the Swiss Federation.*

**Education.** Education is compulsory, though the age limit is set variously by the cantons. Generally speaking, however, primary and a certain amount of secondary education is required of all Swiss youth. Education in the primary and secondary levels is free. In 1947 the total enrolled in the primary schools was 433,332. Teachers numbered 13,692. All secondary schools for the same period showed an enrollment of 75,546 with 3,043 teachers. There are seven universities: Basel, Zürich, Bern, Geneva, Lausanne, Fribourg, and Neuchâtel. In addition to these, a great number of technical schools offer specialized training in the crafts and professions. The Federal Polytechnic School attracts students from all over Europe. The Commercial University at St. Gallen is also well known. The last two schools, though ostensibly offering university work, are considered technical schools.

## HISTORY

**Founding of the Swiss Confederation.** The Helvetians, the first recorded inhabitants of the region now known as Switzerland, were subjugated by the Romans under Julius Caesar. When the Roman Empire went into decline in the fifth century, the territory was occupied by the Alamanni, Franks, and Burgundians. During the period of Charlemagne the Franks extended their control over the entire area, ruling through the duke of Swabia. When the Carolingian empire disintegrated in the ninth century, the Swabian dukes came forward and took over the government of the region, but they were unable to maintain their control because of the era's feudalistic tendencies. As the thirteenth century opened the territory presented an array of feudal principalities. The counts of the House of Hapsburg exercised suzerainty over a number of these and at this time began to expand their feudal claims in the remaining number. Fearing that the growing power of the Hapsburgs would circumscribe the liberties that they enjoyed under their local lords, the cantons of Uri, Schwyz (from which the name of Switzerland comes), and Unterwalden appealed to Frederick II, ruler of the Holy Roman Empire.

*Charter of 1231.* In response to their plea, Frederick issued a charter in 1231 granting them exemption from the authority of the local feudal lords and bringing them under the direct authority of the emperor. With the death of Frederick II in 1250 the imperial power entered a period of rapid decline, marked initially by a civil war in which two factions contended for the throne and during which the empire was without a head (the Great Interregnum). The disturbed condition of the empire allowed the three Swiss cantons to develop their own political institutions, but at the same time it gave the Hapsburg counts an opportunity to extend their control in the region.

*Defeat of the Hapsburgs.* However, the counts were busy with the conquest of Austria and delayed sending forces against the cantons. The cantons used this time to mature their separate governments and form a defensive league in 1291. When the Hapsburgs finally moved against the cantons in 1315, the forces of the league inflicted a smashing defeat at the Battle of Morgarten. After this triumph the league proceeded to enlarge itself between 1315 and 1353 by admitting to membership the cantons of Luzern, Zürich, Glarus, Zug, and Bern. By winning the battles of Sempach and Näfels, the eight cantons achieved real independence; the Hapsburgs in the treaty of 1389 renounced all feudal claims on the cantons. Thereafter the only authority with which the cantons had to reckon was that of the emperor, and that became increasingly ineffective as the empire declined.

**Rise to Power.** After the peace of 1389 the Swiss League or Confederation (*Eidgenossenschaft*), as it was called in the Priest's Charter of 1370, proceeded to follow the pattern of

development so clearly outlined by the events of the fourteenth century. New cantons were admitted, and by 1513 the confederation consisted of thirteen members. The cantons perfected their alliance so that it assumed more of the aspects of a federal union, although regular meetings of a constitutionally established diet were not yet inaugurated. In the fifteenth and sixteenth centuries the confederation began to play a role as a European power, fighting wars with Charles of Burgundy, concluding alliances with Louis XI of France, and even holding a feeble and tentative balance of power in the Italian wars of the French kings with the Hapsburgs. The Reformation saw Zwingli leading Zürich, and Calvin dominating Geneva, while the southern cantons remained within the Catholic fold. But the confederation was disrupted only temporarily by these religious differences; the menace of the outside powers promoted unity in spite of such profound differences and gave added substance to the federal principle. The Peace of Westphalia in 1648 marked the recognition of Swiss independence by all the European states.

AERIAL VIEW OF THE CITY OF GENEVA, SWITZERLAND

J. GABERELL

**The Helvetic Republic.** The French Revolution had a profound effect on the Swiss cantons. In 1797 the French armies, to counter a similar military move by Austria, invaded the cantons and by the spring of the following year had completed the conquest of the comparatively weak cantons. The French established the Helvetic Republic in place of the loose arrangement of the Swiss Confederation. The Constitution of 1798 established for the first time in Swiss history a strong central government. The government exercised control over money, trade, justice, police, and even the army. The French administrative system was adopted, and the central government was empowered to appoint prefects and subprefects to the cantons and districts. These powers were exercised by the central government through a bicameral legislature, a supreme court, and a directory which was ostensibly responsible to the legislature. Such basic doctrines as the ultimate sovereignty of the people and inalienable rights were clearly stated in the 1798 constitution. The remnants of feudalism were abolished, and the estates of the Church were confiscated. Though accepted by some of the Swiss, the constitution was opposed by others, and the Swiss were divided into two factions, the Centralists and the Federalists. Napoleon tried to reconcile the factions and in 1802 issued a new constitution.

**Recovery of Independence.** This, like the Helvetic Constitution, could only be maintained by force of arms, and with the French defeat in 1815 the Swiss cantons individually disavowed the French-sponsored government and tried to resurrect the old confederation. But the advantages of a stronger federal union had been clearly seen during the period of French control, and the cantons signed the federal pact on Aug. 7, 1815, continuing the Diet, though with powers greatly modified. The next three decades saw the enactment in Switzerland of reactionary Metternichian measures. Nevertheless, there was evident a steady growth of liberal sentiment in the country, and in 1847 the federal Diet, reflecting this sentiment, ordered the expulsion of the Jesuits, whereupon seven Catholic cantons tried to secede. The federal government, marshaling the military forces of twelve and one-half cantons, very quickly forced the secessionists to capitulate. In 1848, as a result of the War of the Sonderbund, a new constitution was adopted giving the federal government greater powers. This constitution existed until it was replaced in 1874. Possibly the most important aspect of recent Swiss history has been the development of the socialist movement in Switzerland.

**International Developments.** After World War I Switzerland made every effort to find a convenient formula that would enable it to join the League of Nations and yet not jeopardize its policy of neutrality. On Feb. 13, 1920, Switzerland obtained from the Council of the League the recognition that its neutrality was not incompatible with the Covenant of the League. In the May elections the Swiss nation decided by a small majority to enter the League.

For a short time after the end of World War II Swiss public opinion was in favor of Switzerland's entry into the United Nations on conditions similar to those under which it had joined the League of Nations. However, since Switzerland had not declared war on the Axis, it was eliminated at the start from membership. Moreover, the country was criticized by some of the powers, particularly the Soviet Union, for its wartime role and alleged undemocratic practices. As

the tension between the Western powers and the Soviet Union grew, the Swiss attitude toward the United Nations correspondingly changed. Switzerland's strategic position demanded observance of a strict neutrality lest it be involved in a future war. The division of the United Nations into two camps, which had become increasingly obvious, would have jeopardized Switzerland's neutrality had it joined the United Nations.

In April 1946 the League of Nations Liquidation Commission opened negotiations with Switzerland in connection with the League of Nations premises in Geneva and the proposed establishment of a European regional headquarters for the United Nations. In June 1946 the Swiss government informed the United Nations that it would not allow the meetings of the Security Council in Geneva, on the ground that any action ordered by the Council from Swiss soil might be considered a breach in Swiss neutrality. In November Switzerland placed the former premises of the League and a site of more than 144 acres at the disposal of the United Nations with the provision that if the Security Council or Military Staff Committee should move to Geneva they must not order any warlike action from that city. Further, Switzerland has exhibited interest in those United Nations activities which are of a purely economic or humanitarian nature: the International Court of Justice, the Food and Agricultural Organization, and the United Nations Educational, Scientific, and Cultural Organization. The Security Council prescribed special conditions under which Switzerland could become a party to the statute of the International Court of Justice.

To strengthen its international position as a neutral nation, Switzerland attempted at the end of World War II to re-establish diplomatic relations with the Soviet Union, which had been terminated in 1924 as a result of the assassination of a Soviet delegate to the Conference of Sèvres at which the peace treaty with Turkey was deliberated. The first Swiss overtures were turned down by the Soviet Union in December 1944. Largely through the initiative of the Swiss minister to Belgrade the negotiations were resumed, and diplomatic relations were re-established on Mar. 19, 1946. The renewal of diplomatic relations was followed by a series of commercial agreements between the two countries. In January 1950 Switzerland recognized the Communist government of China. W. S. V.

**SWORD.** *See* Arms and Armor (*Edged Weapons*); Duels and Dueling; Fencing.

**SWORD, KNIGHTS OF THE.** *See* Knights of the Sword.

**SWORD FERN,** a popular name for the genus *Nephrolepis* of about 12 ferns of the true fern family, natives of the tropics and subtropics. Some are terrestrial, some epiphytic. Several are grown as house and conservatory plants, especially the popular Boston fern. G. M. Sm.

**SWORDFISH** or **BROADBILL,** *Xiphias gladius,* a large marine fish of the family Xiphiidae with long sword-shaped snout. The flattened snout, short high dorsal fin, toothless mouth, and lack of scales distinguish it from the marlins, *Makaira.* Only one species of swordfish is known. The fastest swimmer of all the fishes, it ranges around the world in warm and temperate seas. It may attain a length of 14 ft. or more. A record individual, which was taken off New England, weighed 1,000 lb. The swordfish is said to charge through schools of fish, killing by striking to either side with its sword, then returning to devour its prey. Sometimes it feeds in water of 100 fathoms; in calm seas it may swim at the surface, with the tip of the dorsal fin and the tail above water, and frequently leaps clear of the surface. Although the swordfish, when hooked, can drive its sword through the planking of a boat, the broken swords which have been found embedded in the bottoms of ships may have been the result of accidental collision. Reported attacks on boats by swordfish were probably made, instead, by marlin. An excellent food fish, the swordfish is also in great demand for the high vitamin content of oil in the liver. It is one of the finest of big game fishes. E. C. R.

**SWORDTAIL,** *Xiphophorus helleri,* a small cyprinodont fish found native in fresh waters of Mexico and Central America. The male is easily recognized by the long lower lobe of the caudal fin, which may be almost as long as the rest of the fish. A favorite aquarium species, the swordtail hybridizes with the platy, *Platypoecilus maculata,* producing many interesting and beautiful varieties. The female may bear from 100 to 200 living young. Thriving on small vegetation such as algae, swordtails are easily kept in a five-gallon aquarium if the temperature is about 75° to 80° F. Since they are active jumpers, the tanks should be covered. The males are pugnacious and too many should not be kept in a small tank. The females are larger, measuring 5 in. in length. The platy, which is similar in form but not so slender, and without the extension of the tail fin, may be kept under the same conditions. E. C. R.

**SWOYERSVILLE** [swɔi′ərzvɪl], a borough in northeastern Pennsylvania, situated in Luzerne Co. on the Susquehanna River, 3 mi. north of Wilkes-Barre. Swoyersville, incorporated as a borough in 1888, is governed by a mayor and council. The borough was named in honor of Henry Swoyer, a coal operator. Coal mining is the chief occupation of the borough's residents. Local factories produce textiles and ornamental iron and steel. Pop. 1950, 7,795.

**SYCAMORE** [sɪ′kəmər], the name given in the United States to the native species of *Platanus.* The Old World species of sycamore are commonly known as plane or plane tree. The common sycamore, *P. occidentalis,* called also buttonwood, of the eastern United States, attains a greater diameter than any other American broadleaf tree, having a trunk 11 ft. in diameter above its enlarged base. It sometimes reaches a height of 170 ft. The reddish-brown bark exfoliates in large, thin scales, exposing irregular patches of a whitish inner bark. The tree has broad, slightly lobed leaves and globular fruit heads suspended on slender stalks. The moderately strong and hard, reddish-brown wood is used principally for furniture and food containers.

The smaller California sycamore, *P. racemosa,* having three- to five-lobed leaves, grows abundantly in valleys from the upper Sacramento to Lower California. It grows to 90 ft. The similar Arizona sycamore, *P. wrighti,* having deeply lobed leaves, is found in Arizona, New Mexico, and Sonora.

The name sycamore was originally applied to *Ficus sycamorus,* a species of fig native to Egypt and Syria. Sycamore is also the commonly accepted name in England for the sycamore maple, *Acer pseudo-platanus.* W. D. B.

**SYDENHAM, THOMAS** [sɪ′dənəm] (1624-1689), British physician, called the "English Hippocrates," was born in Wynford Eagle, Dorset, Sept. 10, 1624. He entered Oxford in 1642, left to enlist in Cromwell's army, but later returned and was graduated as a Bachelor of Medicine in

1648. Sydenham did research study at Montpelier and in 1663 was licensed by the College of Physicians to practice in London. In 1676 he received the degree of Doctor of Medicine from Cambridge University. Sydenham was primarily a great clinician and emphasized personal observation, simple remedies, and the best possible care for the patient. He was the first to differentiate satisfactorily between measles and scarlet fever, and between acute rheumatism and gout. He introduced the cooling method in the treatment of smallpox and fevers, and was one of the first to prescribe iron for anemia. He popularized the use of quinine from cinchona bark in ague or malaria, treated syphilis with mercury compounds, and prescribed a life in the open for phthisis. "Sydenham's laudanum," a tincture of opium with cinnamon, cloves, and saffron added, was a popular remedy for many years. Sydenham made a special study of epidemics in relation to seasons, years, and ages, and revived the Hippocratic idea of "epidemic constitution"; he classified and defined chorea, hysteria, and gout, as well as malaria and smallpox. His conception of infectious conditions as specific entities was far in advance of its time. Sydenham was not a court physician, probably because his radical methods angered and alienated the influential physicians of that period, but his practice included many important people and among his close friends were the chemist Robert Boyle and the philosopher John Locke. Sydenham's fresh approach to the subject of medicine did much to free it from the antiquated theories and practices of the Middle Ages. His writings include treatises in Latin on epidemics, gout, hysteria, smallpox, fevers, and venereal diseases, and discussions of pathology and therapeutics. Sydenham died in London, Dec. 6, 1689. D. D. M.

**SYDENHAM'S CHOREA.** *See* CHOREA.

**SYDNEY,** the capital of New South Wales and largest city of Australasia, situated on the east central coast of Australia in County Cumberland, at 33° 52′ S. lat. and 151° 12′ E. long. It lies 60 mi. south of Newcastle and 450 mi. northeast of Melbourne, at a distance of 6,647 nautical mi. from San Francisco and 4,306 mi. from Singapore. The actual city limits encompass an area of about 9 sq. mi. along the southern shore of Port Jackson, one of the largest and best protected natural harbors in the world; clustered around the city in three directions, southward to the shores of Botany Bay, westward across the Sydney Basin, and northward along the northern shore of Port Jackson, are 48 suburban municipalities which, with Sydney, comprise a metropolitan area inhabited by a fifth of the total population of Australia. The climate is of the modified, humid subtropical type, with an average annual precipitation of 48 in. and an average annual mean temperature of 72° F. July, the coldest month, has an average mean of 52° F.; January, the warmest, 72° F. During the winter (May to September) westerly winds prevail.

Although Captain James Cook sighted and named Port Jackson in 1770, he did not enter it. In January 1788, Captain Arthur Phillip arrived at Botany Bay with a shipload of convicts to establish a British penal station. The colony was removed the same year from Botany Bay to Port Jackson.

COURTESY OF THE AUSTRALIAN NEWS AND INFORMATION BUREAU

*Airview of the harbor at Sydney, New South Wales, Australia, one of the world's finest and most active ports*

At first there were very few free settlers, but after the transportation of convicts from Great Britain was halted, about 1840, the number rapidly increased. The population, only 3,000 in 1815, had grown by 1861 to 97,061 and by 1901 to 487,932; since then the total population of the metropolitan area has tripled.

Public buildings of special note include Government House, a castellated structure in Victorian Gothic style; two cathedrals, Anglican and Roman Catholic; and many buildings of modern architectural design. Adjoining are the Botanic Gardens, notable for their tropical flora, and the National Historical Museum, oldest in the Commonwealth, founded in 1836.

From Dawes Point on the south to Milson Point on the north, a 3,770-ft. bridge, completed in 1932, spans the harbor; it has a main span of 1,652 ft. providing a clearance of 170 ft. for vessels. Port facilities have been extensively developed to make Port Jackson one of the busiest of the British Commonwealth, handling more than 11,000,000 tons of cargo annually. Cockatoo Island is a naval shipbuilding and repair base, with a huge graving dock; here in 1940 and 1941 the *Mauretania, Queen Elizabeth,* and *Queen Mary* were converted for use as troop transports, and later many American warships were repaired. Cultural facilities include the University of Sydney; the public library, with more than half a million volumes; the Mitchell Library of Australiana; a technological museum; a conservatory of music; and art galleries and theatres. The Town Hall is the chief auditorium for concerts. The city and its suburbs constitute the chief industrial, commercial, banking, shipping, and communications center in Australia. The apparel, metalworking, machinery, food and beverage, electrical equipment, and shipbuilding industries are among the more important. Of prime importance in the local economy is wool marketing. Chief exports, besides wool, include wheat, meat, butter, and fruit. Pop. 1947, 1,484,434. W. McE.

**SYDNEY,** a port city and the county town of Cape Breton Co., Nova Scotia, Canada, situated on a good harbor, about 200 mi. northeast of Halifax. Rail facilities are provided by the Sydney and Louisburg and the Canadian National railways. Air service is furnished by the Trans-Canada Air Lines. The city has steamer connections with the Bras d'Or Lake ports, northern Cape Breton, Prince Edward Island, and Newfoundland. Founded in 1784, Sydney was incorporated as a town in 1885 and as a city in 1904. Nearby are the extensive Cape Breton coal fields. Large quantities of coal are shipped from the city to St. Lawrence River ports. Iron ore is brought by ship from Bell Island, Newfoundland, for processing in Sydney, which is one of the most important steel centers in Canada. Rails, ship plates, nails, and wire are leading products of the city's industries. Pop. 1951, 31,317. D. F. P.

**SYDNEY, UNIVERSITY OF,** at Sydney, Australia, on a campus of 140 acres. The university was incorporated by an act of the legislature of New South Wales, which received the Royal Assent of Great Britain on Oct. 1, 1850. By a royal charter, issued on Feb. 7, 1858, the graduates of the University of Sydney were accorded the same status as that of other university graduates within the United Kingdom. A number of colleges are included within the organization of the university: St. Paul's (Anglican), St. John's (Roman Catholic), St. Andrew's (Presbyterian), Wesley (Methodist), Women's (undenominational), and Sancta Sophia (Roman Catholic Women). New England University at Armidale is an associate college. The teaching staff includes faculties of agriculture, architecture, arts, dentistry, economics, engineering, law, medicine, science, and veterinary science. A. L. H-Q.

**SYDNEY MINES,** a town in Cape Breton Co., Nova Scotia, Canada, situated on Sydney Harbor, 8 mi. north of Sydney and 200 mi. northeast of Halifax. It is on Provincial Highway 5 and is served by the Canadian National Railways. It was incorporated in 1889. It is the North American terminus of a transatlantic cable. Coal mining is the chief occupation of the district. About 800,000 tons of coal are mined annually. Pop. 1951, 8,410. D. F. P.

**SYENITE** [sai′ənait], an intrusive igneous rock similar to granite in appearance, but containing little or no quartz. Essential minerals are potash feldspar, with lesser amounts of plagioclase feldspar (oligoclase), hornblende, biotite, and pyroxene. Common accessory minerals are apatite, magnetite, sphene, and zircon. Syenite, by an increase in quartz content, grades into granite; an increase in plagioclase makes it a monzonite; and an increase in both quartz and plagioclase produces granodiorite. On the other hand, an increase in the darker minerals, accompanied by a change of feldspar from the potash-soda to the soda-lime types, causes syenite to pass into diorite. Changes in texture from granitoid to porphyritic result in syenite porphyry, and the fine-grained border zones of syenite intrusions are trachytic. Nepheline syenite is a variety containing greasy-looking grains of the feldspathoid nepheline. Sodalite or corundum may also be present in these rocks. Both syenite and nepheline syenite occur in large intrusive bodies, which, however, are by no means as extensive or widespread as are the granite batholiths. Syenite rocks occur in the White Mountains of New Hampshire, in northern Wisconsin, south and west of Little Rock, Arkansas, and, in Europe, in especially well-known exposures in the vicinity of Oslo. It is quarried to a minor extent and marketed as granite. Nepheline syenite, on the other hand, has separate use as a substitute for feldspar in the manufacture of glass and other ceramic products. It is exploited for this purpose in Ontario, Canada, and in the U.S.S.R. About 40,000 tons of Canadian nepheline syenite is imported annually into the United States. K. K. L.

**SYLACAUGA** [sɪləkɔ′gə], a city in central Alabama, situated in Talladega Co., 40 mi. southeast of Birmingham, in an agricultural area where corn, cotton, and hay are important crops. Pine timber and marble are natural resources of the region. In 1950 the government was of the mayor-council type. Sylacauga has the distinction of having supplied from its quarries marble for such world-famous buildings as the presidential palace in Havana, Cuba, and the United States Supreme Court Building in Washington, D.C. Transportation is afforded by the Central of Georgia and the Louisville & Nashville railroads. In addition to marble, local industries include cotton ginning and the manufacture of cottonseed oil, cotton cloth, mattresses, caskets, soft drinks, fertilizer, lumber, and bricks. Pop. 1950, 9,606.

**SYLLABLE,** in linguistic science, a unit of utterance which is variously defined. The concept expressed by the term *syllable* is by no means clear, and it has provoked much discussion, some phoneticians going so far as to deny its validity altogether.

The existence of the entity called "syllable" is assumed in the metrics of most languages, which are based, in great part, and sometimes predominantly, on a count of syllables.

Thus Sanskrit, Greek, and Latin metrics are based on a certain number of long and short syllables, alternating with each other according to certain schemes. The number of syllables is strictly observed in Vedic and Classical Sanskrit verse and in Greek and Latin Alcaics, Sapphics, and other Aeolic verse forms. In Greek and Latin epic and tragic verse it is limited to a certain range; for example, the epic hexameter of Homer and Vergil is limited to no less than 12 and no more than 17 syllables, the two extremes being comparatively rare. Among the modern languages, those of the Romance group are relatively strict in the matter of syllable counting; Italian verses, indeed, receive their names from the number of syllables they contain (*settenario, ottonario, novenario, decasillabo, endecasillabo, dodecasillabo,* etc.). The ancient Germanic verse (as found in the *Edda* or *Beowulf,* for example) was much freer, and some of this freedom still survives in modern English and German poetry. However, an arbitrary alteration of the number of syllables in a verse shocks a reader of English poetry probably no less than it shocks a reader of Italian, and this sensitivity offers excellent evidence of the existence of the syllable as a clear acoustic entity. In fact, the syllable is perhaps best defined in precisely those terms, as a unit of utterance that constitutes "a clear acoustic entity."

One widely accepted definition of the syllable, "a word, or a section of a word, containing a single vowel," is dangerously close to being tautological, for a vowel may be defined as a sound that is capable, in itself, of forming a syllable. Thus, *oil* may be called a syllable on the ground that it contains only one vowel, inasmuch as the *i* is essentially a consonant or a half consonant (usually called a *semivowel*); but this reasoning is circular, for all that prevents the *i* in *oil* from being a vowel is the fact that it is not syllabic. Moreover, sounds that from the point of view of their articulation are usually considered consonants, such as *r, l, m, n, z,* and *s,* occasionally "carry" the syllable and so perform the essential function of vowels. Thus, in English, the *l* of *battle* and the *m* of *rhythm* are called "syllabic" or "vocalic," and similar sounds existed in Indo-European and still exist in German and in several Slavic languages. In like manner, the *s* in *pst, sst,* and similar articulations may be called syllabic, for even though it is voiceless, it has the vocalic element of duration.

In general, every syllable is marked by a single high pitch of sonority. It follows that syllables are separated by depressions of sonority, which are usually represented by consonants, but sometimes simply by a short silence or hiatus (as in *naïve*). The lowest depression of sonority is the limit or boundary between the syllables; it varies a great deal in the different languages, and is by no means easy to recognize.

Syllables are called checked or closed when they end in a consonant (Lat. *ac, nec, et;* Eng. *as, pot, fat*); unchecked or open when they end in a vowel (Lat. *nē, dā;* Eng. *bee, she*). When the vowels of two successive syllables are separated by a single consonant, this consonant belongs, in Greek, Latin, and the Romance languages, to the following syllable. Thus, the first syllable of Latin *a-mor,* French *a-mour,* Italian *a-more,* and Spanish *a-mor* is open. On the other hand, when the two vowels are separated by two consonants (as in Latin *fac-tum,* Italian *can-to,* French *par-tage*), usually the first consonant goes with the preceding syllable (which is closed), and the second with the following syllable. When three or four consonants appear between two vowels, the first consonant usually belongs to the first syllable, the others to the following (Latin *cas-tra, tem-plum*). These rules also apply in general to English, with the exception that a consonant following a short vowel is usually regarded as belonging to the preceding syllable (*nev-er, cit-ies, ad-amant*). The division of syllables at the end of the written or printed line is in some cases arbitrary and does not correspond to the real syllabification; it is frequently based on the etymology rather than the sound of words.

Some indirect conclusions as to the division between syllables can be drawn from the metric of quantitative languages and, in some cases, from historical linguistics. In Greek and Latin metrics a closed syllable is always considered long, just as an open syllable is long when it contains a long vowel. It follows that *făctum,* which (like *fātum*) constitutes a trochaic foot (— ◡), must be divided *făc-tum,* for its first syllable has a short vowel and could not fulfill its function in the trochee if it were not closed.

An exception may be made, both in Greek and in Latin metrics, for the so-called *positio debilis* ("weak position"), which arises when an occlusive is followed by *m, n, r,* or *l.* In words like *pătrem, intĕgrum,* or *tenĕbrae,* for example, the penultimate syllable can be either short or long, as the poet chooses. The Romance languages show that in spoken Latin the short articulation prevailed in the end, for these languages regularly have an open syllable in these cases: French *père* from Latin *pa-trem, entier* from *intĕgrum,* Spanish *tinieblas* from *tenĕbrae.* However, the penultimate syllable of *tenebrae* and *integrum* must have been long at some time, for otherwise the accent would be on the antepenult in accordance with the laws of Latin accent.

Many languages show a trend toward a certain quantitative equalization of syllables, shortening those that are relatively long and lengthening those that are relatively short. Latin, for example, shortens all long vowels before the combination of a nasal or liquid with a stop; thus **calēntem,* from **calēre,* becomes *calĕntem,* Spanish *caliente.* The same development takes place in Greek and in Lithuanian. In the Romance languages, which have lost the Latin distinction between short and long vowels, all vowels in open syllables tend to become long and all vowels in closed syllables tend to become short. Thus Italian has *fā-to, dā-to, viē-ne, pā-ni,* and also *făt-to, găt-to, vĕn-ne, păn-ni.* Since in closed syllables the consonants add a certain length of time to the articulation of the syllable, all syllables thus tend to equality of duration. Some languages, including Japanese, have only open syllables (*Hirohita, Hiroshima, Nagasaki,* etc.), and Protoslavic approaches the same condition. This tendency, which is frequent in many languages, is also discernible in French and Spanish, Latin *testa* becoming (bisyllabic) French *tête* and *factam* becoming (bisyllabic) *faite.* However, in recent times French has started dropping the so-called "mute *e*," and thereby many syllables that were once open become closed again. Thus many consonantic groups, which had long disappeared from the language, have now been revived, and groups that never existed (such as *šv* in *cheval,* now pronounced *šval*) are appearing. This tendency is favored, in French as in all modern European languages, by the introduction of enormous numbers of foreign learned words, especially of Italian, Latin and Greek origin.

In all modern European languages, stressed syllables are, as a rule, longer and stronger than unstressed ones. In the Germanic languages, especially, the consequence has been that unstressed syllables weaken or fall, Latin *eleēmosynās* becoming English *alms* and *paraverēdus* becoming German *Pferd.* The same trend exists, in a weaker degree, in the Romance languages, in Russian, and elsewhere; thus French has *manger* for Latin *manducāre* and *août* for *augustum.* It appears that there was no such trend in ancient languages in which pitch rather than quantity predominated.

The number of syllables in a word has an important effect on the duration of the component syllables. Other things being equal, the monosyllable is, as a rule, longer than either of the syllables of a bisyllabic word, and each of these is longer than any of the syllables in a polysyllabic word. The longer the word, in fact, the shorter the syllable. The monosyllable *pork* is longer than the syllable *pork-* in *porker,* and this in turn is longer than the *porc-* in *porcupine.*

The number of syllables composing a word varies enormously from one language to another. Chinese, at least in its literary variety, has only monosyllables. Monosyllables are very frequent in English; in fact, the Germanic element in English is almost exclusively monosyllabic. French and German have many monosyllables, whereas Italian has almost none and Spanish very few. There is in Europe a general trend toward a reduction in the size of words, but in some languages, including the Slavic ones and Spanish and Italian, this trend has not gone very far. In English, while most Germanic words and many others that are in common use are monosyllabic, the learned words, whether French, Italian, Latin, or especially Greek, are in their vast majority polysyllabic. This division in the English vocabulary suggests to many speakers of English the notion that polysyllabics are learned, pretentious, technical, and pedantic words, which the average mind does not understand and the average man does not use. The English language is therefore virtually split into two sections, and the gap shows no sign of closing. The same gap exists in several other European languages, and it is widened, as it is in English also, by the special consonantic clusters that characterize learned words of Latin and Greek origin.

The tendency of spoken English toward monosyllabism is also apparent in abbreviations and nicknames, which are usually monosyllabic (e.g., *Jap, Kraut, Yank; Jim, Jack, Fred*). In French and in Italian, abbreviations are usually bisyllabic, French having *le métro* (*le métropolitain*), *le bachot* (*le baccalauréat*), *Loulou, Nana, Fifi, Mimi, Kiki,* and Italian having *Gigi, Gianni, Toto,* and many more.

**SYLLOGISM.** *See* Logic.

**SYLPHIDES, LES** [lɛ si'lfi'd], an abstract ballet in one scene by Michel Fokine, danced to orchestrations of piano selections of Frédéric Chopin. Using the same music, Fokine originally prepared an elaborate ballet called *Chopiniana,* which was first presented at the Maryinsky Theatre in St. Petersburg on Mar. 21, 1908. This was soon transferred into the classically simple *Les Sylphides,* which had its première at the Théâtre du Chatelet in Paris on June 2, 1909, during the first Parisian season of the Diaghilev company. Perennial opening number for ballet programs, *Les Sylphides* has probably been presented more times than any other ballet. Anna Pavlova, who appeared with Vaslav Nijinsky in its first performance, often included in her programs a ballet called *Chopiniana,* which was probably an adaptation of the original version of *Les Sylphides.*

The costumes worn by the female dancers in *Les Sylphides* were designed in the early nineteenth century by the painter Eugène Lami (1800-1890) for *La Sylphide,* a ballet in two acts by Filippo Taglioni to a score by Jean Schneitzhoeffer. The libretto of this early work was by Adolphe Nourrit, tenor of the Paris Opéra, and was based in part upon the novel *Trilby, ou Le Lutin d'Angail* (1822) by Charles Nodier. Maria Taglioni as Sylphide wore the so-called long *tutu,* which became the traditional costume of the Romantic ballet. *See also* Ballet.

F. G. P.

**SYLT** [zɪ'lt], a German island in the North Sea, the largest of the North Frisian Islands. It lies off the west coast of the Jutland peninsula opposite the Danish-German frontier. Sylt is 22 mi. long from north to south and in most parts less than a mile wide, except near the middle of the island where a peninsula extends 7 mi. eastward. The total area is about 37 sq. mi. The interior is low, for the most part, with marshes, heath, and moor predominating.

Sylt was virtually independent during the Middle Ages; it became part of the Duchy of Schleswig in 1435. The island was invaded by Sweden in 1643 and held for a year by the Swedes before they were driven out. The Danes had possession in 1864 during their war with Prussia, but the Prussians captured the island before the end of the war and it has remained in German hands since. Fortified in the 1930's, Sylt was the first German territory bombed in World War II, and after the war was included in the British zone of occupation. Sylt, connected to the mainland by rail via the Hindenburgdamm, a causeway, is a popular resort and its main source of income is the tourist trade. Keitum is the largest town on the island, while Westerland and Kampen are two of the most popular resort villages. Despite protective measures, the island is continually menaced by the erosive action of the sea, which has washed away considerable land over the years. Pop. 1950, 22,238.

**SYLVAN LAKE PARK.** *See* Canadian Provincial Parks.

**SYLVANUS.** *See* Silvanus.

**SYLVESTER I, ST.** (c.275-335), a Roman by birth, became pope in 314, shortly after Constantine had revolutionized religious conditions in the Roman Empire by showing official favor to Christianity. For lack of authentic information, many legends became attached to Sylvester's name in the course of centuries. The best known is the so-called "Donation of Constantine," a document which relates how Constantine, who was afflicted with leprosy, sought out Sylvester in his hiding place on Mount Soracte and was baptized after being cured by the pontiff. In return Constantine is said to have granted Sylvester the privilege of wearing imperial insignia, and to have given him not only supremacy over all the Christian churches of the Empire, but also temporal dominion of Rome, Italy, and the West. This document is an early medieval forgery. Reliable information on Sylvester is scanty despite his long pontificate (314-335). His feast is celebrated Dec. 31.

E. A. R.

**SYLVESTRINES** [sɪlvɛ'strɪnz], members of a Roman Catholic minor monastic congregation that was founded by St. Sylvester Gozzolini at Monte Fano near Fabriano, Italy, in 1231, and approved by Pope Innocent IV in 1247. Following the strictest form of the Rule of St. Benedict, yet not federated with other Benedictine congregations, the blue-clad Sylvestrines place great stress on poverty. Long confined almost exclusively to Italy, the congregation established a mission in Ceylon in 1855. In 1942 the congregation numbered one hundred and twelve professed monks. In 1947 there were twelve in the diocese of Detroit, where they were established in 1910. The Sylvestrine nuns have never been numerous.

W. C.

**SYMBIOSIS** [sɪ'mbaio'sɪs], or mutualism, an intimate association of two different organisms, the symbionts, in which each is benefited by the partnership. There are degrees of symbiosis, just as there are degrees of parasitism.

The partnership is sometimes essential to the life of each symbiont, the death of one often resulting in the death of the other. But the association is not always so strict, for each symbiont, if conditions warrant, may be capable of independent existence. However, growth and multiplication are more vigorous in association than when either species lives alone. In still other instances, the balance may be so delicate that, if one of the symbionts is favored, it will outgrow the other and eventually become a parasite, or predator, on its associate.

The phenomenon of symbiosis occurs in most of the plant and animal phyla. The association between leguminous plants and nitrogen-fixing bacteria is an excellent example. The bacteria cause the roots to develop nodules, and take their nourishment from the plant, in return for which they transform atmospheric nitrogen into compounds which the plant can utilize. Many bacteria live symbiotically with other organisms. Cellulose-eating animals, such as the horse, the cow, and the sheep, have bacteria in their stomachs which partially digest their food. In exchange, the bacteria receive all their food from them.

Another example of symbiosis is found in the lichens. These plants represent intimate associations between various species of colorless plants (fungi) and unicellular green plants (algae). The fungus supplies attachment and protection, and absorbs the raw materials of food. In turn, the fungus obtains the photosynthetic products from the algae. Each can live independently under favorable conditions, but in partnership they can withstand hardships which many plants cannot. Thus lichens often populate rocky regions which otherwise would be barren.

Symbiotic relations between unicellular green (Zoochlorellae) and brown or yellow algae (Zooxanthellae) and animals are not uncommon. Here the algal symbiont supplies the organic products of photosynthesis, while the animal, in return, affords a favorable abode and materials necessary for the life of the chlorophyll-bearing organisms. Zoochlorellae are found living in association with fresh-water protozoa such as *Paramecium bursaria, Stentor polymorpha,* and *Stentor amethystinus.* Among the fresh-water Metazoa, these green algae are associated with *Chlorohydra viridissima* and with certain fresh-water sponges. Zooxanthellae are found living with marine Protozoa such as *Paraeuplotes tortugensis,* and with certain Foraminifera and Radiolaria. Similar algae are found associated with certain corals (Millepora), sea anemones, and in certain flatworms (e.g. Convoluta).

Symbiotic relations between Protozoa and Metazoa also occur. The protozoan symbionts are usually found in the stomach and intestine of wood-eating animals, such as termites and wood roaches. They perform the same function as do the cellulose-digesting bacteria. The association of the termites and their Protozoa is strict; neither can live without the other.

An instance of symbiosis between two Metazoa is that involving the hermit crab and sea anemones: the latter give additional protection to the crab by concealing it, and by means of many poisonous stinging threads with which their tentacles are covered. The anemones in turn are transported from place to place into new feeding grounds, and also may gather in food which is missed by the crab. Another interesting example is represented by ants and plant lice, or aphids. The defenseless aphids are protected, herded, and "milked" by the ants in order to obtain honeydew from them, a secretion of the plant lice, which the ants eat. R. F. N.

**SYMBOLIC LOGIC** (or mathematical logic), the science of correct inference, especially as developed by use of mathematical methods and with the help of special symbols that enable one to avoid much of the ambiguity of ordinary language.

This field of study arose in the eighteenth and nineteenth centuries as an outgrowth from both traditional mathematics and the ancient logic of Aristotle. It joined these hitherto diverse subjects into a single subject, or at least provided them with a common foundation. The earliest writers on symbolic logic were such mathematicians and philosophers as G. W. Leibniz, George Boole, C. S. Peirce, Gottlob Frege, Ernst Schröder, and Giuseppe Peano. During the first half of the twentieth century numerous important contributions to the subject were made by scholars in Europe, Great Britain, and the United States. Especially notable among European scholars were David Hilbert and Kurt Gödel. Some of the well-known British and American contributors were Bertrand Russell, A. N. Whitehead, H. M. Sheffer, E. L. Post, C. I. Lewis, Alonzo Church, H. B. Curry, and W. V. Quine.

Symbolic logic seeks to attain all the rigor and clarity of the most exact mathematics, but without the restrictions that limit ordinary mathematics to dealing only with numbers and numerical relationships. Any subject-matter whatsoever is susceptible to analysis by symbolic logic. Much use is made of the notions of "class" (as in any classification), "relationship," and "proposition." A great weakness of Aristotelian logic was its lack of any adequate account of the logical nature and structure of relationships. Until the advent of symbolic logic, no systematic way had been provided for reasoning about any relationships other than those appearing in geometry or in numerical mathematics. This perhaps accounted in part for the great advances that had been made by the physical sciences in contrast to the lesser progress achieved by ethics, political science, philosophy, and the social sciences generally. The first important application of symbolic logic to an empirical science occurred in 1937 with the appearance of J. H. Woodger's book, *The Axiomatic Method in Biology.* Subsequent writers have applied symbolic logic to psychology and neurophysiology.

The problem of proving that certain systems of mathematical logic are free from contradiction has been regarded as a crucial problem by symbolic logicians ever since some previously acceptable methods of reasoning were found to give rise to contradictions. The sort of contradiction that may be obtained by use of such previously acceptable methods is well illustrated by the Russell Paradox (discovered by Bertrand Russell), which may be stated as follows: Let $Z$ be the class of those classes which are not members of themselves. (For example, the class of all books is not itself a book. Hence it is not a member of itself. Hence it is a member of $Z$.) Now either $Z$ is a member of $Z$, or else $Z$ is not a member of $Z$. If $Z$ is a member of $Z$, then $Z$ is a member of itself, so $Z$ is not a member of $Z$ after all. On the other hand, if $Z$ is not a member of $Z$, then $Z$ is one of those classes which are not members of themselves, and so $Z$ is after all a member of $Z$. Hence, paradoxically, $Z$ can neither be a member of itself nor fail to be a member of itself. Paradoxes of this kind can be avoided by various more or less satisfactory methods. One of these methods is the "theory of types," according to which a class always is treated as being of a different "type" from its members, and any assertion or denial that a class is a member of itself is regarded as "meaningless" owing to a confusion of types. Thus it becomes a meaningless question to ask whether or not $Z$ is a member of $Z$.

There is no complete uniformity or standardization in the choice of symbols employed by writers in symbolic logic, but there is a certain amount of agreement. The following table

illustrates approximately and in part the kind of notation that is most commonly employed:

| *Symbolic Expression.* | *Meaning of the Expression.* |
|---|---|
| $a=b$ | $a$ is identical with $b$. |
| $\backsim(a=b)$ | $a$ is not identical with $b$. |
| $p\cdot q$ | (It is the case that) $p$ and $q$ (are both true). |
| $p \mathrm{v} q$ | (It is the case that) $p$ or $q$ (is true). |
| $\backsim p$ | Not $p$. (Or: $p$ is false.) (Or: It is not the case that $p$.) |
| $p \supset q$ | If $p$ then $q$. (Or: $p$ only if $q$.) |
| $p \equiv q$ | $p$ if and only if $q$. |
| $a \in b$ | $a$ is a member of $b$. |
| $\backsim(a \epsilon b)$ | $a$ is not a member of $b$. |
| $a \subset o$ | $a$ is included in $b$. (Or: Every member of $a$ is a member of $b$.) (Or: $a$ is a subclass of $b$.) |
| $Fa$ | $a$ has the attribute $F$. |
| $(\exists x)$ | There is something $x$ such that . . . |
| $(\exists x)Fx$ | There is something $x$ such that $x$ has the attribute $F$. (Or: Something has the attribute $F$.) |
| $(\exists x)(x=a)$ | There is something $x$ such that $x$ is identical with $a$. (Or: Something is identical with $a$.) |
| $(x)$ | Each thing $x$ is such that . . . |
| $(x)(x=x)$ | Each thing $x$ is such that $x$ is identical with $x$. (Or: Each thing is identical with itself.) |
| $(\hat{x})$ | The class of things $x$ such that . . . |
| $\hat{x}Fx$ | The class of things $x$ such that $x$ has the attribute $F$. (Or: The class of things having the attribute $F$.) |
| $(a \epsilon \hat{x}Fx) \equiv Fa$ | $a$ is a member of the class of things having the attribute $F$ if and only if $a$ has the attribute $F$. |
| $Fa \supset (a \epsilon \hat{x}(Fx \mathrm{v} Gx))$ | If $a$ has the attribute $F$ then $a$ is a member of the class of things having the attribute $F$ or the attribute $G$. |
| $((a \epsilon b) \cdot (b \subset c)) \supset (a \epsilon c)$ | If $a$ is a member of $b$, and $b$ is included in $c$, then $a$ is a member of $c$. |

The last three symbolic expressions above (as well as "$(\exists x)\ (x=a)$" and "$(x)\ (x=x)$") are illustrations of expressions that are regarded true on logical grounds alone. Such expressions would be expected to appear as theorems in any fairly adequate system of logic.

In formulating a system of symbolic logic it is usual to specify which expressions are regarded as "axioms" of the system and then to state certain "rules of procedure" according to which other expressions, known as "theorems" of the system, are derivable from the axioms or from previously derived theorems. This process is supposed to require no reference to the actual or possible meanings of the symbols concerned, and so is said to belong to the "syntax" of the system concerned. The "semantics" of a system, on the other hand, does involve the assignment of meanings to various expressions of the system, but it is not concerned with indicating which expressions are axioms or theorems of the system.

**SYMBOLISTS,** a group of French poets of the end of the nineteenth century, among whom are included Stéphane Mallarmé, Jules Laforgue, Gustave Kahn, Francis Viélé-Griffin, Stuart Merrill, Jean Moréas, Paul Fort, Maurice Maeterlinck, Remy de Gourmont, Emile Verhaeren, Henri de Régnier, Albert Samain, René Ghil, Francis Jammes, and others. Arthur Rimbaud and Paul Verlaine are sometimes considered forerunners of the movement, and among the poets of the twentieth century, Paul Valéry and Paul Claudel are sometimes presented as the direct heirs of the Symbolists.

Symbolism, like Impressionism in painting, is an attempt to abandon ready-made patterns and rules and to seize purer and more essential qualities in the artistic medium. Valéry has defined Symbolism as a common attempt, made by schools of poetry which often seemed at odds, to borrow for poetry the properties of music. This definition includes in its scope such poets as Mallarmé, Verlaine, Laforgue, and Ghil, who were all musical in different ways. All tried to lift French poetry out of its traditional oratory and to use words not for their expository qualities but for their shades and undertones of meaning. The union of the arts, the fusion of sensations, abstract words used concretely, and concrete words used adjectivally are some of the devices that they employed. At the root of all these experiments lay a belief in the supremacy of art over every other means of expression or knowledge, a belief incorporated in an idealistic philosophy: the world that humans look at is not the world they would see if they knew it through the "correspondences" that their various senses could establish among sensations.

After 1900, there was a strong reaction against the Symbolists. They were considered café poets, lacking in vigor, too fond of artificial ornaments, and too much like J. K. Huysmans' hero, Des Esseintes. Nevertheless, the literary experiments of Symbolism cannot be dismissed. Among these, the most important is free verse, which resulted from a long process of dissolution of traditional forms and has now become an important department of poetry. The attacks the Symbolists faced were often undeserved. There existed indeed a "fin de Siècle" or "decadent" affectation and a foggy or atmospheric type of art which were identified by some with Symbolism; but at no time since the Renaissance have so many experiments been carried out on the poetic values of words, and no school of poetry has so much enriched the technical means of poets.

The Symbolist movement in the theatre is best represented by Maurice Maeterlinck, who tried to revive the poetic drama and dissolve the characters of his plays in thematic composition. Among the adherents of the movement was one ex-

cellent critic, Remy de Gourmont. As for the novel, Proust's works can be considered as a brilliant finale to the life and the ideas of the Symbolist period. R. Ta.

**SYMMACHUS, ST.** [sĭ'məkəs] (c. 450-514), pope, born a pagan in Sardinia, was baptized at Rome. In the troubles following the death of Anastasius II, whose policy in regard to the schism of Acacius was unpopular, Symmachus was elected pope by the anti-Byzantine majority. The faction of Anastasius opposed to him the priest Laurentius. Both sides appealed to Theodoric the Great, who decided in favor of Symmachus. The early years of the pontificate, 498-506, were troubled by charges and countercharges. Notable is the decision of the Roman Synod of 501, which declared that the quarrels must be submitted to the tribunal of God since the chair of Peter must not be judged by any man. It was only in 506, when Theodoric vigorously supported the cause of Symmachus, that the Laurentian schism ceased to divide the Roman Church. The violent persecution of the orthodox Eastern Christians by the Monophysite emperor Anastasius prevented Symmachus from healing the schism between Rome and Constantinople. E. A. R.

**SYMONDS, JOHN ADDINGTON** [sĭ'mənz] (1840-1893), English historian, scholar, poet, was born in Bristol on Oct. 5, 1840. He was educated at Harrow and at Oxford, and he remained at the latter for some time as a tutor. His most important work, the *History of the Renaissance in Italy* (1875-1886), is rich in valuable comment and picturesque detail, although it is not a highly unified study nor a continuous one. In 1887 he translated the *Autobiography of Benvenuto Cellini*. He wrote brief studies of Jonson, Sidney, and Shelley. His verse is best represented by *Many Moods* (1878) and *New and Old* (1880). He translated the Greek poets and the sonnets of Michelangelo and Campanella. Symonds died in Rome on April 19, 1893. C. D.

**SYMONS, ARTHUR** [sai'mənz] (1865-1945), English editor, poet, and critic, was born in Wales, on Feb. 28, 1865, of Cornish parents. In the eighties and early nineties he wrote for the *Athenaeum,* the *Saturday Review,* and the *Academy*. He contributed frequently to the *Yellow Book,* and in 1896 he founded the short-lived but brilliant *Savoy*. His criticism, impressionistic and trenchant, ranged over a variety of subjects in both French and English literature, some of his best-known critical works being *The Symbolist Movement in Literature* (1899), *The Romantic Movement in English Poetry* (1909), and *Studies in Elizabethan Drama* (1920). Symons' poetry is in the decadent tradition characteristic of the nineties. His volumes of poems, *Days and Nights* (1889), *Silhouettes* (1892), and *London Nights* (1895), indicate his general disillusionment and illustrate the perfection of his technique. He died in Wittersham, Kent, on Jan. 22, 1945. C. D.

**SYMPATHETIC INK.** *See* Inks.

**SYMPATHETIC NERVOUS SYSTEM.** *See* Nervous System (*Autonomic Nervous System*).

**SYMPHONIC POEM** or **TONE POEM,** a one-movement orchestral composition based on a poetic or other nonmusical "program" and treated in the manner of the symphony; it is chiefly identified with nineteenth-century Romanticism. The ancestor of the symphonic poem, which was evolved and popularized by Franz Liszt around the middle of the nineteenth century, was the program symphony, examples of which are Beethoven's *Pastoral Symphony* (first published 1809) and Berlioz' *Symphonie Fantastique* (1831). Liszt also wrote program symphonies in "Dante" (1856) and "Faust" (1857); the chief differences between them and his thirteen symphonic poems, especially *Prometheus* (1856), *Tasso* (first published 1856), and the very popular *Les Préludes* (first published 1856), are the greater influence of the program in the symphonic poems on the character and form of the music, and the use there of but one movement, although that may be subdivided into sections of considerable contrast.

Where Liszt's programs had been chiefly ideas, subsequent composers often based their works on more concrete subjects and treated them more literally. Among celebrated examples, Smetana's *The Moldau* (from the suite *My Country,* 1879) patriotically depicts the course of the great Bohemian river, Saint-Saëns' *La Danse macabre* (1874) (*The Dance of Death*) describes a grotesque graveyard frolic, Tchaikovsky's *Romeo and Juliet* (1870) emphasizes the main forces and conflicts in the Shakespeare classic, and Paul Dukas's *The Sorcerer's Apprentice* (1897) relates an amusingly dramatic incident. On the other hand, Debussy's *Prelude to the Afternoon of a Faun* (1894) merely reflects moods and impressions.

Richard Strauss's literal and highly successful tone poems, especially *Don Juan* (1888), *Death and Transfiguration* (1889), *Till Eulenspiegel's Merry Pranks* (1895), and *A Hero's Life* (1898), qualify him as the principal successor to Liszt and perhaps the greatest composer of symphonic poems. But while Arthur Honegger, in *Pacific 231* (1924), and Alexander Mossolov, in *The Steel Foundry* (1930), have attained at least as great a degree of literalism in the twentieth century, many twentieth-century composers have turned away from program music in general. However, in spite of time-honored objections to a dependence on extramusical factors, one may note that the best nineteenth-century symphonic poems, quite apart from their programs, are constructed according to the soundest principles of "absolute" music. W. S. N.

**SYMPHONY,** an extended musical composition for orchestra, usually in four contrasting movements, following the plan of the sonata. The word "symphony," which has a connotation of "consonance" or "harmony" in its original Greek form, was first generally employed to designate a musical composition in the early seventeenth century. Until the second quarter of the eighteenth century, however, in its Italian form (sinfonia) it meant an introductory piece of some sort, especially an overture to an operatic work. Nevertheless, the three-movement (fast-slow-fast) opera sinfonia, evolved at the end of the seventeenth century by Alessandro Scarlatti and others, was an important ancestor of the modern symphony. Its significance was demonstrated by the sinfonie that were composed independently of opera and performed as concert pieces, such as the early sinfonie by Giovanni Battista Sammartini (1701-1775).

The modern symphony is the instrumental product par excellence of the fully developed Classical era, the first great examples being among the most mature works of Mozart and Joseph Haydn. Many other antecedents of musical Classicism beside the Italian sinfonia contributed to produce the modern symphony around the middle of the eighteenth century. Of prime importance were major refinements in the art of orchestration: the strings became the melodic foundation, and the figured bass was discarded, an act which resulted in more precise harmonic and soloistic assignments for the wind instruments. Notable among the composers who brought about these orchestral refinements were Jean Philippe Rameau and François Joseph Gossec in Paris, Johann Stamitz in Mann-

heim, C. P. E. Bach in Hamburg, and Haydn and Mozart in Vienna. Also of great importance to the development of the symphony, and in part influenced by the new orchestration, were the trends toward broader, more pliant themes, capable of varied development, dissection, and expansion; a more homophonic texture, at its best enlivened by the interplay of thematic motives in harmonic counterpoint; the clear opposition of moods or ideas, both within a single theme and between contrasting themes; and highly organized, sectional designs, in particular that design subsequently known as "sonata form."

Among the larger Classical instrumental forms, all of which followed the sonata form more or less closely, the symphony was quite naturally given the most extensive treatment since its "instrument" (the orchestra) provided the widest range of expression. In the main, the Classical symphony represented a more serious and developed treatment of the sonata idea than either the solo keyboard sonata or the string quartet. It made more extensive use of the introduction, the bridge, and the coda; it exploited its material more thoroughly; and it achieved greater climaxes and contrasts. A further distinction was to be found in the use of a minuet or, beginning with Beethoven, a scherzo before the finale of the symphony; this was used in the principal chamber-music forms but not, as a rule, in either the concerto or the solo sonata.

Although Haydn wrote at least 104 symphonies in the usual eighteenth-century sets of three or more, and Mozart forty-one, only a few of their last and greatest symphonies are frequently performed. These include the E-flat major, G-minor, and C-major, or "Jupiter," symphonies written in 1788 by Mozart and the "Surprise" (G-major, 1791), "Military" G-major, 1794), and "Clock" (D-major, 1794) symphonies among the twelve written by Haydn between 1791 and 1795 for the London impresario Johann Peter Salomon. Subsequent composers preferred to write fewer symphonies, endeavoring to imbue each with relatively more distinctive and consequential character.

The nine symphonies by Beethoven—including the Third in E-flat major ("Eroica," 1804), the Fifth in C-minor ("Fate," 1805), and the Ninth in D-minor (known as the "Choral Symphony" because of the introduction of soloists and chorus in the finale, 1823)—mark a peak in symphonic literature, being unexcelled in formal logic and intensity of expression. Fitting successors are the nine symphonies of Schubert, especially the "Unfinished" (the Eighth in B-minor, 1822), a work of great melodic and dramatic power which the composer cast aside after completing only two movements, and the monumental and heroic Ninth in C-major (1828), which was called the "Seventh" in the days before the scores of the "Unfinished" and a fragmentary E-minor symphony (1821) had been discovered. Beethoven and Schubert both combined elements of Classicism and Romanticism in their symphonies; Schubert not infrequently revealed a characteristic Romantic penchant for intimate harmonic color and lyricism at the expense of close-knit formal structures.

A major part of the nineteenth-century symphonic activity went into the symphonic poem, but full-fledged symphonies continued to be written, although these were frequently programmatic. Among those that were not programmatic are the four great symphonies by Johannes Brahms, completed between 1876 and 1885, which go far toward reconciling the formal logic of Beethoven with the rich harmonic and melodic content of full Romanticism. Other enduring symphonies, all showing the influence of Classicism, are several by Mendelssohn and Schumann, written in the 1830's and 1840's; the programmatic *"Symphonie fantastique"* (1830) by Berlioz and the "Dante" (1856) and "Faust" (1857) symphonies by Liszt; the nine gigantic symphonies (1863-1894) by the devout and inspired mystic, Anton Bruckner, who often built up his initial ideas into full chorale-like themes; and a like number (1888-1909) by the impassioned and philosophical epicist, Gustav Mahler, who made extensive use of choruses and solo voices. Among the most popular symphonies composed more recently are César Franck's (the D-minor, 1888); Anton Dvořák's Fifth Symphony in E-minor, "From the New World" (1893); Tchaikovsky's Fourth in F-minor (1877), Fifth in E-minor (1888), and Sixth, or *"Pathétique,"* in B-minor (1893); Rachmaninoff's Second in E-minor (1907); and Sibelius' First in E-minor (1899), Second in D-major (1901), and Fifth in E-flat major (1915).

Among the contemporary composers who have convincingly demonstrated the continuing vitality of the symphony are Ralph Vaughan Williams, Paul Hindemith, Dimitri Shostakovich, Sergei Prokofiev, Igor Stravinsky, Roy Harris, and Aaron Copland. Notwithstanding the very different styles of these composers, their more recent symphonies are remarkably alike in their strong rhythmic vitality and in their efficient and compact terseness of expression. The old elements of the sonata form survive in these symphonies chiefly as general principles and seldom as structural details. W. S. N.

**SYMPLEGADES** [sɪmplɛ′gədiz], or the "Clashing Islands," in Greek legend, two islands or rocks at the north end of the Bosporus which crushed ships that passed between them. The Argo was the first vessel to sail through safely. G. E. D.

**SYNAGOGUE** [sɪ′nəgɒg], a Jewish house of worship. The term is derived from the Greek word *συναγωγή* ("assembly") and corresponds to the Hebrew word *ḳeneseth*. The Hebrew terms for synagogue are *bet ha-ḳeneseth* ("house of assembly") and *bet ha-tefilah* ("house of prayer"). The Yiddish word *shul* (from German *Schule*) and the term *temple* also commonly designate Jewish houses of worship: in popular American usage the former usually applies to Orthodox synagogues, the latter to Reform synagogues.

The date of the origin of the synagogue is uncertain, though it is highly probable that the institution was developed soon after the destruction of the First Temple (586 B.C.), and it is known that numerous synagogues existed in the period of the Second Temple (516 B.C.-A.D. 70). The synagogue has played an immensely important role in Jewish spiritual history. From its earliest days it served as a meeting house and a house of study as well as a house of prayer. In modern times many of the larger synagogues function as community centers, offering cultural, educational, and social, as well as religious facilities. A great number of synagogues conduct a *Talmud Torah,* or a religious school for children.

Since there is no prescribed architectural form for a synagogue, examples have varied from the simplest of buildings, or even a room in a building used for other purposes, to magnificent structures in a wide variety of architectural styles. On the inside, the essential furnishings are a platform (called *almemar* or *bimah*) and the holy ark in which the scrolls of the Torah (Pentateuch) are kept; other traditional furnishings are the perpetual light, a representation of the tables of the law (both over the holy ark), and two candelabra. In Orthodox synagogues men and women are seated apart, some synagogues having separate galleries for women.

Synagogues operate independently, and each congregation elects its own officers. The number of paid functionaries

generally include a rabbi who preaches and acts as spiritual leader of the congregation; a *hazzan,* or cantor, who leads the services; a reader, who reads from the scrolls of the law; and a *shammas* (*shammash*), or sexton, who supervises the building and fulfills a number of miscellaneous duties. The position of *hazzan* originally entailed numerous duties, but in the course of time these have been relegated to the *shammas* and other personnel, his sole remaining duty being to lead the prayers. On festivals the *hazzan* may be assisted by a male choir. Mixed choirs are found only in Reform (or advanced Conservative) temples, and it is only in these that organs or other musical instruments are played at services.

**Synagogue Council of America.** In the United States, the Orthodox, Conservative, and Reform synagogue groups have formed national synagogue associations. An over-all synagogue association is the Synagogue Council of America, founded in 1925, in which all the groups are represented and which concerns itself with problems regarding the entire American Jewish community.

**Great Synagogue.** The Great Synagogue (or Synod) was a legislative assembly which according to Jewish tradition functioned in Palestine between the fifth and third centuries B.C. Historical data on this subject are slight; it is not certain how long the assembly functioned and in fact some have doubted whether it existed at all. In the Book of Nehemiah there is an account of Nehemiah's convention of the elders of the community and this assembly presumably became the Great Synagogue; scholars have questioned, however, whether this group met for more than the one occasion or, if it did, whether it functioned for more than one generation.

Traditionally, however, the Men of the Great Synagogue (who supposedly included many of the Scribes) were the spiritual heirs of the prophets. There are a number of references to them in the Talmud and other Jewish writings, and they are credited with the establishment of certain religious institutions. *See also* Ark; Judaism (*Organized Judaism in America*); Perpetual Light; Rabbi; Scribes.

**SYNCHROSCOPE.** *See* Measurements, Electrical.

**SYNCHROTON.** *See* Electron and Ion Accelerators (*Synchronous Accelerators*).

**SYNCOPATION** [sɪŋkope′shən], in music, a disruption or contradiction of regular accents and rhythms. Since the end of the sixteenth century, Western music has been based on groups of two or three beats recurring regularly, the first of each group being accented, and whenever this regular pulse of beats and accents is "contradicted" by conflicting patterns, syncopation results. It may be partial, as in most jazz, wherein melodies are "syncopated" against a steady rhythmic background; or it may be complete, with all parts following the new pattern, which thus conflicts with the old pulse still "throbbing" in the listener's memory, as in the scherzo of Schumann's First Symphony, or in many parts of Stravinsky's *Rite of Spring.* W. Li.

**SYNCRETISM** [sɪ′ŋkrɪtɪzəm], in philosophy and religion, the attempt to combine elements taken from different systems of thought, e.g., the fusion of pagan religions by the identification of their gods. The term may be used with disapprobation when the divergent systems are irreconcilably opposed, so that the resulting combination is internally inconsistent or so superficial that the real difficulties are avoided. This was the case with the philosophical development from 200 B.C. to A.D. 250, when the Stoic, Peripatetic, and Platonic schools lost their original distinctiveness. The word is also used as a term of praise when the borrowings are harmonized and integrated by a dominating principle. In this sense it is applied to the work of Plotinus. The term also regularly refers to a movement in seventeenth-century Lutheranism that aimed to submerge the differences among Protestants and Roman Catholics. *See also* Eclecticism.

G. H. Cl.

**SYNDICALISM.** *See* Political Science and Philosophy (*Political Philosophy*).

**SYNGE, JOHN MILLINGTON** [sɪ′ŋ] (1871-1909), Irish dramatist, was born near Dublin on Apr. 16, 1871, and educated at Trinity College, Dublin. After leaving college, he studied music, abandoned it, and tried critical writing. In 1898 he met W. B. Yeats in Paris and received from him the suggestion to study the Irish of the Aran Islands and to write about them. Synge's subsequent work was largely based on the knowledge of the Irish folk that he gained by following this advice. In 1907 he published *The Aran Islands,* a journal and sketches.

JOHN MILLINGTON SYNGE

BROWN BROTHERS

Synge's first play, *In the Shadow of the Glen,* in one act, was produced in 1903 by the Irish National Theatre Society, headed by Yeats. *Riders to the Sea* followed in 1904, and *The Well of the Saints,* in three acts, in 1905. Synge became a director of the Abbey Theatre, along with Yeats and Lady Gregory in 1904.

*In the Shadow of the Glen* and *The Well of the Saints* had been somewhat criticized as irreverent or as misrepresenting the Irish. In 1907 Synge's *The Playboy of the Western World* was presented amid great disorder and Synge and his plays were thereafter for some years regarded with deep suspicion by many of the Irish; his *The Tinker's Wedding,* published in 1909, has never been performed by the Abbey company. Synge's last play, *Deirdre of the Sorrows,* was unfinished when he died in Dublin on Mar. 24, 1909, but in 1910 it was produced as he left it.

Synge's great achievement lay in the writing of an unusually musical and poetic dialogue, which in the mouths of his peasant or folklore characters creates a compelling and deeply moving effect. His humor, though occasionally ironic and bitter, is marked and at times even becomes boisterous. Though his parts are difficult to act, especially

by those not Irish, he has created highly individualized and memorable characters. *See also* PLAYBOY OF THE WESTERN WORLD, THE; RIDERS TO THE SEA. B. Pr.

**SYNOD** [sɪ′nəd], a gathering of ecclesiastical representatives, lawfully convoked, for discussion of and decision on Church matters. It is practically the equivalent of a council, and hence there may be said to be five kinds of synods. The first is ecumenical and is so recognized when the decisions of the synod have been approved by the whole Church; the second is general and may later become ecumenical, if and when its decisions receive universal acceptance; a national synod is a council of the chief ecclesiastics of a nation or country; a provincial synod is a council of the same kind in an ecclesiastical province; and a diocesan synod is the same thing in a diocese. The term *mixed synod* is sometimes used of a council of clergy and laity combined.

In the graduated system of the Presbyterian Church, a synod is the court next above the presbytery, but it is in turn lower than the general assembly. Similarly, in the Methodist Church, the synod is the meeting that functions between the circuits in the conference. In the Russian Church, until World War I, the supreme authority lay in the Holy Governing Synod. It had been created in 1721 by Peter the Great in order to transfer control of the Church from the Patriarch of Moscow to the Crown. While the Holy Synod was composed largely of ecclesiastics, its procurator was the personal representative of the tsar, and in this manner the Church in Russia lost most of its independence.

The term *Robber Synod* is applied in history to the synod which met at Ephesus in the year 449. It was a disorderly and turbulent assembly, and when the report of it was brought to Pope Leo the Great, he remarked that it evidently was not a lawful council at all but a *latrocinium,* or synod of robbers, and the name thus given has persisted through the ages. L. C. L.

**SYNODIC PERIOD** [sɪnɒd′dɪk]. The synodic period of a planet is the time interval between two successive similar aspects of a planet with the sun, as for example between two conjunctions or oppositions. In a synodic period, the faster moving planet gains one lap on the other. A planet's synodic period corresponds to the lunar synodic month, which is, for instance, the interval between two successive new moons. The synodic period of a planet thus differs from the sidereal period, which is the actual period of revolution around the sun with respect to the stars and not to the earth. The relation between the two periods is:

$$\frac{1}{\text{syn.}} = \pm\frac{1}{\text{sid.}} + \frac{1}{\text{sid.}_e},$$

in which syn. is the synodic period of the planet, sid. its sidereal period, and $\text{sid.}_e$ the sidereal period of the earth. The upper signs of the plus and minus symbols are for an inferior planet, and the lower signs are for a superior one. H. S. R.

**SYNTAX** [sɪ′ntæks], in linguistic science, the study of the way in which words are associated to form clauses or sentences. Morphology, the study of forms that indicate the relationship of words, is usually distinguished from syntax, but some scholars deny that any such distinction can be drawn. The difference between the two may be illustrated by an analogy from the game of chess, in which a study of the potential moves of every individual piece is comparable to morphology, while a study of the association of those moves—that is, of the strategy of the game—is comparable to syntax. According to B. Croce and the Neolinguists, however, any such distinction is unscientific because language is an inseparable unity. *See also* MORPHOLOGY; SENTENCE; SUBORDINATION. G. B.

**SYNTHETIC FIBERS,** a term used to describe man-made textile fibers, as distinguished from such naturally occurring fibers as cotton, linen, wool, or silk. Natural fibers have been used for many thousands of years for making ropes and for weaving or knitting fabrics. Beginning about 1890, however, and continuing with growing impetus, there has been a series of attempts by man to make his own fibers from natural and synthetic raw materials, and to control the processes of their manufacture so well that he may predetermine the nature of the product. The success of many of these attempts is attested by the magnitude of the synthetic-fiber industry and by the large number of domestic and industrial products made from rayon, nylon, and similar man-made filaments.

The term synthetic fibers, here applied to all man-made textile fibers, is sometimes used in a narrower sense to describe those filaments which have been completely synthesized from relatively simple chemical units; examples are nylon, dynel, Dacron, etc. These fibers will be referred to here as synthetic-base fibers. On the other hand, those man-made fibers which are formed from relatively complex chemical substances (e.g., cellulose or proteins) are frequently known as regenerated fibers; rayon is an example of this type of fiber. The principal commercial and experimental synthetic fibers are subdivided into regenerated and synthetic-base fibers.

REGENERATED FIBERS:

1. Cellulosic
   a. Viscose rayon
   b. Acetate
   c. Saponified acetate, e.g., Fortisan
   d. Cuprammonium rayon
2. Proteinaceous
   a. Zein (corn protein), e.g., Vicara
   b. Peanut protein, e.g., Ardil
   c. Casein
   d. Chicken-feather keratin
3. Alginate

SYNTHETIC-BASE FIBERS:

1. Acrylonitrile copolymers, e.g., dynel, Vinyon N, Acrilan, X-51
2. Glass, e.g., Fiberglas
3. Polyacrylonitrile, e.g., Orlon
4. Polyamide (nylon)
5. Polyester, e.g., Dacron, Terylene
6. Polyethylene
7. Polystyrene, e.g., Polyfibre
8. Polyvinyl alcohol
9. Vinyl chloride-vinyl acetate copolymer, e.g., Vinyon
10. Vinylidene chloride-vinyl chloride copolymer (saran)

**Characteristics.** In partial explanation of the motivation behind the development of synthetic fibers, it should be realized that each type of textile fiber, whether natural or synthetic, possesses certain physical and chemical characteristics which serve to distinguish it from all other types of fibers, and which recommend or contraindicate its use in any particular application. These properties, which are discussed at greater length in a later section, include both strong points and limitations: some fibers are very strong but brittle, others are weak but flexible; some can be stretched and will resume their original length, others can scarcely be extended at all without breaking; some can be dyed easily with many

types of coloring agents, whereas others are severely limited in the dyes which can be used. The major result of the development of synthetic fibers has been a vast increase in the range of materials from which man can make his cordage and textiles, and many new and useful combinations of properties. Thus, in many instances where a projected use requires a combination of properties not to be found in any existing natural fiber, a synthetic fiber can be "tailor-made" to serve the purpose.

**Distribution.** A second factor which has made the development of synthetic fibers of great importance is the relatively widespread distribution of their raw materials throughout the world, in contrast to more restricted distribution of areas for growing natural fibers. For example, although cotton and wool are grown in many countries, linen, silk, jute, and many other natural fibers are produced in only a few localities, and even cotton must be imported from great distances into some of the world's foremost textile centers. In special circumstances the chief sources of supply of important natural fibers may be cut off; for example, World War II saw the virtual denial of jute, abacá (Manila hemp), and silk imports to the United States and its allies, and synthetic fibers were called upon to perform many of the functions which previously had been in the domain of the natural materials.

## PHYSICAL AND CHEMICAL PROPERTIES OF FIBERS

Among the most obvious physical characteristics of a fiber are size (length and width) and density. The term width is used here in preference to diameter because the cross-section of most fibers is either highly irregular or somewhat oval, instead of round. It is important to know whether a fiber is produced in continuous lengths (as are most synthetic fibers), in relatively-short staple lengths (for example, Vicara), or in both, since this factor affects the manner in which the fiber will be handled in textile machinery as well as influencing the texture or "feel" of yarns and fabrics. Those synthetic fibers which are produced as continuous filaments are ordinarily twisted into yarns containing many of these filaments before leaving the factory, and may be used in weaving or knitting without further mechanical manipulation. Staple fibers, however, must be spun into yarns in a manner similar to that employed for cotton or wool. Yarns composed of continuous filaments are very smooth and may be extremely fine, whereas yarns made from synthetic staple fibers more closely resemble those spun from the natural products.

**Width.** The width of a fiber, which is usually so fine as to be measured in microns (1 micron = 0.00004 in.), may determine, in part, the type of fabric for which it is suited and the manner in which it must be fabricated. Fiber density, the weight per unit volume, not only influences the use to which a fiber may be put but is also employed as a component of a special measure of fiber fineness called denier. The denier of a fiber is defined as the weight in grams of 9,000 meters, and is dependent on both density and cross-sectional measurement. Denier measurements were originally applied to silk but are also commonly used to express the fineness of many synthetic fibers, among them rayon, nylon, and Vinyon. With reference to yarns made from filaments of synthetic fibers, such an expression as 60/20 indicates that the yarn is 60 denier and contains 20 filaments, each filament being approximately 3 denier. A similar unit for expressing yarn fineness is the grex, which is the weight in grams of 10,000 meters of yarn. In addition to these two systems, the older yarn numbering systems designed originally to apply to cotton, wool, and other natural fibers are sometimes used to describe the fineness of synthetic fibers, especially those produced in staple form. Thus, when cotton and rayon are to be blended in a yarn, the rayon-fiber fineness may be expressed in terms of the cotton count, in order to facilitate calculations in the spinning operation.

**Strength and Elasticity.** Probably the most important physical properties of fibers are strength and elasticity. Tensile strength, usually expressed in pounds per square inch, defines the load required to produce rupture of a given fiber. Fiber strength is sometimes reported as tenacity, a term that has acquired a somewhat specialized meaning in fiber technology. In referring to the strength of textile fibers, tenacity is usually expressed in grams per denier; these units cannot be equated with an expression of tensile strength in pounds per square inch unless the density of the fiber is taken into account. Among the synthetic fibers, nylon, glass, and saponified highly-stretched acetate rayon exhibit the highest tensile strengths.

*Elongation.* Ultimate elongation, a measure of the amount a fiber can be stretched before breaking, is customarily expressed in per cent of original length. Usually the extent to which a fiber can be elongated is less for fibers of high tensile strength, whereas low-strength fibers, such as the regenerated proteins, can sometimes be stretched to more than 50 per cent of their original length. Some types of fabrics are required to maintain their original dimensions under stress; for these, a high-strength low-elongation fiber would be chosen. In other cases, a fabric might be required to yield or stretch under a load without breaking; for this purpose, a fiber with a relatively-high ultimate elongation would be used.

*Elastic Recovery.* Elastic recovery refers to the ability of a fiber to recover from various types of deformation, such as extension, compression, and twisting. This property affects the utility of fibrous materials for a great many apparel and industrial purposes, since it is frequently necessary to produce a fabric that will regain its original dimensions and shape after distortion, as in such apparel as women's hosiery and men's suits.

*Stiffness and Toughness.* Among other properties of fibers of the same general category as strength and elasticity are stiffness and toughness. Stiffness is a measure of the resistance of the fiber to deformation; for example, it indicates how much effort must be expended to stretch a fiber a given amount. Stiffness is frequently expressed as the modulus of elasticity. Toughness is a measure of the work absorbed by the fiber while it is stressed to the point of rupture. The nylon used in making glider towropes is an example of a material exhibiting a high degree of toughness; it absorbs a relatively large amount of work before it breaks, for its high tensile strength enables it to withstand large loads and its high ultimate elongation permits large amounts of extension before rupture.

**Moisture Relations.** With the exception of a few synthetic-base fibers, all textile fibers tend to absorb water from a moist atmosphere and to release it as the atmosphere becomes drier. The amount of water held at a specified temperature and humidity, expressed as per cent of the dry fiber weight, is known as "moisture regain." ("Moisture regain" should not be confused with "moisture content" which, as applied to fibers, refers to the amount of water held expressed as a per cent of the total weight of fiber and moisture.) The moisture regain affects the suitability of fibers for many textile applications, as well as governing the conditions under which they may be fabricated. In addition, the absorp-

tion of moisture results in dimensional changes, most important of which is cross-sectional swelling.

**Electrical Properties.** Electrical properties of fibers are important when they are considered for use in condensers, or for insulation on electric wires and cables; the dielectric constant, power factor, and insulation resistance are frequently employed as dimensions of these properties. The retention of electrical charge resulting in "static" in textile fibers is an important consideration, especially in those fibers which absorb very little moisture, such as the synthetic-base fibers.

**Physical and Chemical Resistance.** In nearly all applications of fibrous products, their resistance to the effects of various physical and chemical agents must be considered. The most important of these agents are heat, sunlight, acids, alkalies, and miscellaneous chemicals and organic solvents such as those used in dry cleaning. Resistance to attack by moths and mildew must also be considered in many cases.

**Affinity for Dyes.** A further property of textile fibers is their ability to absorb dyes. The kinds of dyes which may be used vary according to the type of fiber and may influence its utilization for certain purposes, especially in apparel, upholstery, and similar applications. Fastness to light, washing, perspiration, and atmospheric gases depends primarily on the kind of dye used but is also influenced by the fiber to which the dye is applied. For many fibers, notably acetate rayon, special dyes and methods of application have been developed. Some fibers, such as saran, are colored by introducing a pigment into the spinning solution. A special instance of this process is the delustering of rayon by the addition of titanium dioxide to the spinning solution to give yarn with a dull, less reflective appearance.

Physical Properties of Synthetic Fibers

| Fiber | Length | | Width (*Microns*) | Density (*g./cc.*) | Tensile Strength | | Ultimate Elongation (% *at 65% Relative Humidity*) |
|---|---|---|---|---|---|---|---|
| | *Continuous* | *Staple (Inches)* | | | *Dry (Lb./Sq. In.)* | *Wet (% of Dry)* | |
| Viscose rayon* | Yes | 1-8 | 10-43 | 1.50-1.54 | 29,000-78,000 | 44-65 | 9-30 |

## COMPOSITION, MANUFACTURE, AND USES OF SYNTHETIC FIBERS

**Regenerated Fibers.** ***Viscose Rayon.*** Either bleached sulphite wood pulp or cotton linters, or a mixture of both, are used as the source of cellulose in the manufacture of viscose rayon. The cellulose is treated with sodium hydroxide to produce alkali cellulose, which is shredded into crumbs and allowed to age. The aged crumbs are churned with carbon disulphide, and the resulting compound, called cellulose xanthate, is converted into viscose by treatment with dilute sodium hydroxide. After filtering and maturing, the viscose is extruded through a spinneret into a coagulating bath, where the filaments are formed as regenerated cellulose. The yarn, composed of a group of filaments from a single spinneret twisted together, is then washed, desulphurized, bleached, and dried. The filaments can be cut into short lengths of staple fiber instead of being twisted into yarn. In the two oldest viscose-spinning methods, utilizing either the centrifugally operated Topham box or a perforated bobbin for winding the yarn from the spinning bath, subsequent operations such as twisting and washing must be performed separately. A newer system provides for a continuous process of spinning, washing, desulphurizing, and other necessary aftertreatments.

*Uses.* Viscose rayon is produced in greater volume than any other synthetic fiber. It is manufactured in a wide range of deniers and in three tenacities, the latter depending on the extent to which the yarn has been stretched during the spinning operation. Viscose rayon is used, either alone or blended with other fibers, in almost every type of apparel and household fabric, from hosiery and suitings to upholstery, draperies and rugs. Special high-strength viscose-rayon yarns are used for tire cords.

***Acetate.*** The first step in the manufacture of acetate is the acetylation of cellulose, in the form of purified cotton linters, to cellulose triacetate by treatment with acetic anhydride, glacial acetic acid, and a small amount of sulphuric acid as a catalyst. The cellulose triacetate, known as the primary acetate, must then be partially hydrolyzed to a secondary acetate with a somewhat lower acetyl content. The secondary acetate, in the form of flakes, is then washed, dried and dissolved in acetone, and the resulting solution is extruded through a spinneret into warm air. The highly volatile acetone is drawn off as vapor and the cellulose acetate filaments are ready to be twisted into yarn or cut into short lengths of staple fiber. Acetate may be modified by stretching and saponification to produce a regenerated cellulose fiber of unusual strength; Fortisan is an example.

*Uses.* Acetate is produced in several deniers and in two tenacities, regular and high-impact. In addition to its uses in lingerie and other light apparel, it has been extensively employed for electrical insulation by reason of its low moisture regain and excellent dielectric properties. Saponified acetate yarns, because of their unusually high strength and dimensional stability, have been utilized in military and industrial applications where such properties are of special importance.

***Cuprammonium Rayon.*** In the manufacture of cuprammonium rayon, purified cotton linters are mixed with cuprammonium solution, composed of basic copper sulphate and ammonia. The resulting viscous solution is formed into filaments by a stretch-spinning technique in which the solution is forced through a spinneret into a funnel containing deaerated, soft, running water. During passage through the funnel the filaments are stretched, and the ammonia and part of the copper are removed. Most of the remaining copper is removed in a coagulating bath containing dilute sulphuric acid, and the filaments, now combined to form a yarn, are wound into skeins. Any remaining acid and copper sulphate are washed from the skeins with water, and the yarn is left as practically pure regenerated cellulose.

*Uses.* Cuprammonium rayon, which is capable of being spun in extremely fine deniers, has been used mainly in hosiery, lingerie, and similar sheer garments.

***Nitrocellulose Rayon.*** The source of cellulose for the production of nitrocellulose rayon was purified cotton linters, which were treated with a mixture of concentrated nitric and sulphuric acids. The resulting viscous nitrocellulose was extruded through a spinneret and the filaments thus formed were hardened in a bath or air-dried in a special drying chamber. The next step was de-nitration of the filaments to reduce their flammability. The end product, as in the case of viscose and cuprammonium rayon, was a filament of nearly pure regenerated cellulose, though small percentages of nitrogen were sometimes present.

*Uses.* Nitrocellulose rayon was used primarily for apparel such as lingerie and blouses. The yarns were strong and could be produced in fine deniers, but the relatively high manufacturing cost, combined with the hazards involved in handling the raw materials, resulted in the gradual withdrawal of the product from the market. Nitrocellulose rayon has not been manufactured in the United States since 1935.

***Regenerated Protein Fibers.*** The first of the regenerated protein fibers to appear on the market was the Italian product Lanital, made from the milk protein casein according to a process developed by Ferretti from investigations begun in 1924. Another casein fiber, Aralac, was introduced in the United States in 1939. Production of this fiber ceased in 1948, being replaced by zein (corn protein) fiber, e.g., Vicara. More recently, pilot-plant production of protein-base fibers from peanut protein has been started, and experimental fibers have been made from egg albumin, soybeans, chicken-feather keratin, collagen, and other proteins.

The process for manufacturing synthetic protein fibers generally includes dissolving the protein in aqueous alkali, extruding the ripened spinning solution into an acid bath to form filaments, and subsequently treating these by various physical and chemical methods to give the finished fiber. The physical manipulations usually involve stretching, and sometimes steaming followed by stretching. Chemical treatments subsequent to acid precipitation usually include "hardening" or tanning reactions; the most common hardening agent used is formaldehyde. Aftertreatments, such as acetylation, are also used in some cases, such as in commercial casein fiber, to improve the resistance to boiling water.

*Uses.* Protein fiber has been used in blends with wool, cotton, rayon, and other fibers. Its dyeing properties and moisture relations approximate those of wool, and it imparts a wool-like feel to the fabrics in which it is employed. Its applications, usually in blends with other fibers, include suitings, coatings, sweaters, sportswear, and garment linings, and it has been widely used to blend with wool and rabbit hair in the manufacture of felt hats.

***Alginate Fibers.*** The newest members of the family of regenerated fibers, the alginates, stem from researches begun in England in 1937. Alginate fibers are derived from a constituent of seaweed called alginic acid and are produced by extruding an alkaline-earth metal alginate, into an acid bath. Properties of the filaments (such as resistance to aging or to alkalies) may be varied by changing the metal employed in the compound or by treating alginic acid yarn with basic acetates of chromium or beryllium.

*Uses.* A suggested use for alginate fibers is as "scaffolding" yarns for the production of novelty fabrics, where they would be used to support other types of filaments during weaving and would later be dissolved out of the fabric, leaving only a lacy structure composed entirely of the nonalginate filaments.

**Synthetic-base Fibers.** ***Nylon.*** The first commercial nylon yarn was produced in the latter part of 1939, although nylon bristles had been marketed a year earlier. This new substance was the culmination of 10 years of basic research, directed by W. H. Carothers in the laboratories of the E. I. duPont de Nemours Corporation.

Nylon is produced by the reaction of a diamine with a dicarboxylic acid to produce a polyamide chain. Since there are a great many diamines and dicarboxylic acids, the number of possible types of nylon is almost unlimited. The nylon produced commercially on the largest scale is polyhexamethylene adipamide, sometimes known as nylon 66. The hexamethylene diamine and adipic acid are combined to form a nylon salt, which is polymerized to polyhexamethylene adipamide, or nylon. This nylon, which may be cut into chips for storing or blending, is melted and extruded through a spinneret to form nylon filaments. The filaments are drawn out to about four times their original length, in order to provide the necessary tensile strength and elasticity. An elastic nylon, with properties approaching those of rubber, was developed in 1946.

*Uses.* In addition to the use of nylon for women's hosiery, which has absorbed the greater portion of its nonmilitary production, nylon has been employed in the manufacture of other garments such as lingerie, neckties, hats, and dresses. Its unusual tensile properties, combining high strength and good elasticity, have resulted in its use in ropes, parachute fabrics, and similar articles. Other applications of nylon include electrical insulation, tent fabrics, sewing thread, brush bristles, surgical sutures, and insect screening. More recently, nylon staple has been developed and is being used in blends with other fibers, where it contributes markedly to the strength and durability of the product.

***Vinyon.*** Vinyon yarn was first produced in 1939 from a synthetic resin. Vinyon is a copolymer resin of vinyl chloride and vinyl acetate. The resin is dissolved in acetone and spun in air through a spinneret, after which the acetone is recovered and the fibers are stretched. Vinyon N and dynel, more recent products, with improved dyeing properties and greater resistance to heat and organic solvents than regular Vinyon, are copolymers of vinyl chloride and acrylonitrile.

*Uses.* Because of its high resistance to the action of acids, alkalies, and other chemical agents, Vinyon has been used chiefly in the form of industrial filter cloths. Other applications include tent fabrics, awnings, marine cordage, chemically resistant hose, shoe fabrics, and upholstery.

***Saran.*** Development of vinylidene chloride began in the early 1930's, and commercial production of the thermoplastic resin saran, a vinylidene chloride-vinyl chloride copolymer, was announced in 1940. The vinylidene chloride and vinyl chloride are polymerized and the resulting copolymer is extruded into a die and stretched; the filaments thus produced are considerably larger in diameter than most other synthetic fibers. Saran is sold to producers of plastics and filaments, who may adopt other names for their products.

*Uses.* Saran is highly resistant to the action of light and of chemical agents, and has been used primarily in upholstery fabrics, special ropes, filter fabrics, screens, and handbags.

***Glass Fibers (Fiberglas).*** Commercial production of the only man-made inorganic textile fiber, Fiberglas, was begun in 1938. Glass filaments had been drawn to fairly fine diameters for many years and had been used for insulation and, occasionally, in novelty fabrics. Prior to the development of Fiberglas, however, the diameter was still too coarse to allow the flexibility necessary in most textile applications.

To produce Fiberglas, glass marbles, the chemical composition of which varies with the use intended for the end product, are melted in an electric furnace. The molten glass flows through a bushing containing many small orifices. If it is desired to manufacture a continuous filament, the streams emerging from the tiny holes are caught on a high-speed winding mechanism and drawn out to extremely fine diameters in continuous strands. Staple fibers of glass are made by subjecting the streams of molten glass emerging from the bushing to jets of high-pressure steam or air.

*Uses.* Because of its high tensile strength, electrical insulation resistance, noninflammability, and resistance to the action of most chemicals except alkalies, Fiberglas has been employed in a wide range of industrial applications. Masses of glass fibers are used for thermal and sound insulation, and for air filtration. Fabrics woven from Fiberglas are used for filtration of chemicals, electrical insulation, and for industrial textiles where resistance to high temperatures is required. In the domestic field, glass textiles have been used in draperies and novelty fabrics.

***Polyethylene Fibers.*** Polyethylene fibers were announced in 1944 as a result of the synthesis of straight-chain polymers from ethylene, a derivative of petroleum. Polyethylene resins are produced by direct polymerization of ethylene at high temperatures and pressures. The polymer is then melted, extruded through many fine holes, and drawn.

*Uses.* Polyethylene monofilaments (single large-diameter fibers) have been used in marine cordage, insect screening, and filter cloths, where their excellent resistance to attack by chemical agents is utilized. Experiments are continuing in an effort to develop polyethylene filaments suitable for additional applications.

***Polyester Fibers.*** Dacron is an example of a polyester fiber, a long-chain polymer resulting from the condensation of a dicarboxylic acid and a dihydroxy alcohol. In this case, the reaction takes place between terephthalic acid and ethylene glycol under high vacuum and high temperature in the absence of air. The resulting polymer is melted and spun at high temperatures.

*Uses.* Actually there are two varieties of this fiber which are produced. The high strength of the filament form is suggestive of uses similar to those of nylon. The staple form is better adapted to garments and is suggested for typical wool uses.

***Polystyrene Fiber.*** Polyfibre, announced in 1944, is a highly oriented fiber of unusually small diameter, produced by the polymerization of styrene to polystyrene. The fibers are not spun from a spinneret in the usual manner but are drawn from the molten polymer.

*Uses.* Polyfibre has been used primarily for low-temperature thermal insulation.

***Polyvinyl Alcohol Fibers.*** Development of polyvinyl alcohol fibers has been carried on since 1937. Polyvinyl alcohol is obtained by the hydrolysis of a polymerized vinyl compound, such as polyvinyl acetate, with an alcohol. The resulting compound may be rendered insoluble in hot and cold water and common organic solvents, if desired, by further reaction with a compound capable of forming a cross-linked structure between the chains of polyvinyl alcohol; one such substance is methacrylic acid monomer. Filaments may be spun from spinnerets in the usual manner.

*Uses.* Polyvinyl alcohol fibers have been suggested where solubility in water is advantageous, e.g., as an auxiliary yarn in knitting nylon hosiery and for surgical sutures.

***Polyacrylonitrile Fibers.*** Orlon is spun from a polymer of acrylonitrile. Other fibers are formed from copolymers of acrylonitrile and such substances as itaconic acid esters. Vinyon N is a copolymer of acrylonitrile and vinyl chloride.

*Uses.* The uses of polyacrylonitrile fibers are similar to those of Dacron.

**Blends.** There is a steadily growing trend towards the use of synthetic fibers, especially synthetic-base fibers, in blends with natural textile fibers. In this way, the advantages of both types of fiber may be exploited and the disadvantages, minimized. *See also* Cellulose; Plastics.

**SYRA.** *See* Síros.

**SYRACUSE** or **SIRACUSA** [sɪ′rəkyus, si′rɑku′zɑ], a province and the capital of that province, situated in southeastern Sicily.

**The City.** The main, and older, section of the city lies on Ortygia Island in the Ionian Sea, separated from the mainland by a narrow canal. The newer sections are found on the mainland. Syracuse's main harbor comprises a bay 3 mi. long and 1½ mi. wide, formed in large part by the peninsula and island on which the city is situated. A smaller port, accessible only to very small vessels, lies north of the island. The city is a popular tourist spot, and it is the focal point for excursions to the extensive ruins of the powerful ancient Greek metropolis of the same name lying mainly on the low plateau northwest of the modern city. These ruins include a Greek temple and theatre, sections of ancient fortifications and walls, aqueducts, a Roman amphitheatre, and catacombs. During World War II the city's populace used these catacombs as places of refuge. The ruins did not suffer any damage during the fighting and bombing raids prior to Syracuse's capture by British forces in July 1943, but the city itself was damaged, including a number of the historic monuments, notably the archaeological museum, the cathedral (the former Temple of Athena), and the Beneventano Palace. The Fountain of Arethusa, noted since Classical antiquity, is one of the city's most outstanding landmarks.

Syracuse flourished in ancient times, when it was Sicily's most powerful city and the center of Greek civilization on the island. It was first settled by settlers from Corinth in the eighth century B.C., and the city grew and prospered politically and commercially. The fifth century B.C. was marked by wars involving Athens and other Greek states in the Greek motherland. In the fourth century attacks by Carthage were rebuffed, but in the following century Syracuse joined the Carthaginians in the Second Punic War against Rome. In the famous Siege of Syracuse, which lasted for three years, Roman forces attacking by land and sea under the command of Marcellus finally captured and sacked the city in 212 B.C. Archimedes, the noted scientist who was a native of the city, was instrumental in prolonging the siege by devising various machines to repel the enemy. He employed beams swinging outward from the walls with heavy weights attached to crash down on the Roman ships. The story of Archimedes' attempts to burn the enemy fleet with huge reflectors is unlikely for there is no mention of its occurrence until the second century of the Christian Era.

*THE BATTLE OF SYRACUSE IN SEPTEMBER 413 B.C., A NAVAL ENGAGEMENT OF THE PELOPONNESIAN WAR IN WHICH THE BESIEGING ATHENIANS WERE DEFEATED AND THEIR FLEET WAS DESTROYED*

FROM AN OLD WOOD ENGRAVING

CULVER SERVICE

Under Roman rule Syracuse lost its importance, though it retained its status as the capital of Sicily. With the decline of Rome the city came under the control of the Vandals and Ostrogoths, and in 535 it fell to Byzantine armies under Belisarius. The Moslems, after repeated attacks, took the city in 878 and remained in control, save for two very brief intervals of Greek rule, until 1085, when the Normans conquered it. Thenceforth Syracuse generally shared the political history of Sicily. During the Napoleonic Wars its port was used by Lord Nelson in his blockade of the Italian peninsula. The Bourbon garrison of Syracuse surrendered to the liberating forces of Garibaldi on Sept. 3, 1860. Pop. (off. est. 1947), 64,584.

**The Province.** The province of Syracuse, encompassing 849 sq. mi., is Italy's southernmost province. In general the

terrain is low and flat along the coast with hilly country farther inland. The soil is fertile and produces large crops of cereals, fruits, olives, and vegetables. Over half the population works on the land. In addition to the capital, the other cities of consequence are Lentini, Avola, Noto, Pachino, Augusta, and Floridia. Pop. (off. est. 1947), 312,000.

R. G. W.

**SYRACUSE** [sɪ′rəkyus], a city in central New York, the county seat of Onondaga Co., about 75 mi. southeast of Rochester, on the New York State Barge Canal, near Onondaga Lake. The city lies on hilly ground overlooking the southern end of the lake in a rich farming region, near the Finger Lakes and Adirondack Mountains vacation areas.

The Syracuse region was the home of the Onondaga Indian Nation and the meeting place of the Five Nations of the Iroquois. When the Jesuit missionary Simon Le Moyne visited the city's site in 1654 he discovered that the springs which the Indians contended to be the home of evil spirits were salt springs. Ephraim Webster became the first permanent white settler of the city when he opened a trading post, which came to be known as Webster's Landing, in 1786. The original development and prosperity of the city of Syracuse was based on the exploitation of the numerous springs, and for nearly a century the district was the country's principal source of supply for salt. Asa Danforth and Comfort Tyler began commercial production in 1788. Salina and Geddes villages grew up around the salt works. Syracuse developed in the 1820's at the junction of great north-south and east-west valleys which placed it on the route of canals, turnpikes, railroads, and, later, airlines. Syracuse was incorporated as a village in 1825, and as a city in 1848. Absorbing the earlier villages, its commercial and industrial activity offset the transfer of salt manufacturing to rock salt centers. Nevertheless, present use of Syracuse area salt in chemical production in the vicinity greatly exceeds quantities formerly shipped from the city for table and dairy use. The city is the seat of Syracuse University and Le Moyne College. Syracuse has the mayor-council form of government.

Transportation is supplied by the New York Central and the Delaware, Lackawanna & Western railroads and the American and Colonial airlines. Syracuse's chief industries manufacture furniture, typewriters, farm implements, automobile gears and accessories, iron and steel products, electrical and electronics equipment, cans, pottery, air conditioning equipment, drugs, and clothing. Pop. 1950, 220,583.

**SYRACUSE UNIVERSITY,** an accredited, coeducational, privately controlled institution (except for the New York State College of Forestry), founded and fostered by the Methodist Episcopal Church. The university occupies a 795-acre campus in Syracuse, N.Y. Syracuse University, chartered in 1870, absorbed Genesee College that was at Lima, N.Y., chartered in 1849. Instruction began at Syracuse in 1871. The numerous divisions of the university were founded as follows: College of Liberal Arts, 1871; College of Medicine, 1872 (a continuation of the Geneva College of Medicine, 1835-1872; incorporated into the State University of New York, 1950); College of Fine Arts, 1873; College of Law, 1895; L. C. Smith College of Applied Science, 1901; Summer Session, 1902; Teachers College, 1906 (became the School of Education, 1934); Library School, 1908; New York State College of Forestry at Syracuse University (founded by New York State, 1911; became part of the State University of New York, 1949); Graduate School, 1911; School of Speech and Dramatic Art, 1913; School of the University Hospital of the Good Shepherd, 1915 (became the School of Nursing, 1943); College of Home Economics, 1921 (established as a school, 1918); University College, 1918 (founded as the School of Extension Teaching and of Adult Education); College of Business Administration, 1920 (first established as a school, 1919); Maxwell Graduate School of Citizenship and Public Affairs, 1924; School of Journalism, 1934; Institute of Industrial Research, 1946; Utica College of Syracuse University, 1946.

Degrees offered include the A.B., B.S., B.E. in various engineering curricula, B.F.A., B.Mus., B.Arch., LL.B., B.L.S., M.A., Ed.D., M.S., M.D., and Ph.D. The D.D.S. emphasizes broad preparation as well as research in the social sciences. A new one-year program leads to the M.S. in radio and television. Army and Air Force R.O.T.C. units have been established; military training is optional and may be substituted for the physical education requirement.

The extensive library houses many special collections, some of which are Stephen Crane; Frederic Goudy; local and regional history; Methodism in New York; the Smallwood collection of natural history in the United States before 1875; Syracuse University archives; Wolfe-Leavenworth collection of portraits of early scientists; forestry library; Russian collection on history, economics, geography, literature; journalism library; library science collection; and French literature of the early nineteenth century.

Scholarship and fellowship aid is extremely generous, with some of it being set aside specifically for foreign students. Funds are available for loans, and opportunities for self-help enable many of the students to earn part or all of their expenses. Dormitories and fraternity and sorority houses provide living accommodations for men and women. *For statistics see* COLLEGES AND UNIVERSITIES.

**SYR DARYA** [sɪ′r daryɑ′], the ancient Jaxartes, a river flowing principally through the Kazakh Soviet Socialist Republic of the Soviet Union. The Naryn, rising in the Petrov glacier of the Ak-shurak Hills, and the Kara Darya, rising in the snowfields of the Fergana Hills, in the Kirghiz S.S.R., join at Namangan to form the Syr Darya. The upper course of the Syr Darya flows from east to west, but near Leninabad the river turns north and then northwest, flowing into the Aral Sea at its northeastern extremity. In its 1,100-mi. length the Syr Darya flows through deep gorges with steep gradients in the east near the high Tien Shan, through a broad basin, the Fergana, in its middle course near Kokand, and through a desert, where the river constantly loses water in its course north of Tashkent. It enters the Aral Sea through a low marshy delta which is continually increasing. The river is at its widest in its middle course, where it averages a width of 400 ft. The tributaries of the Syr Darya are unimportant, with the exception of the Chirchik, which passes through the ancient town of Tashkent, the main center in the river's drainage basin. The Syr Darya has little value as a navigable waterway, since its mouth is blocked by a bar covered by only 3 ft. of water most of the time, and its middle course is broken by many sand bars. Extensive irrigation works have been built in the Fergana Basin in which cotton and melons are the chief crops.

J. E. V.

**SYRIA** [sɪ′rɪə], a republic located in the Near East. Confusion sometimes arises concerning it since Syria for centuries has been the name given to the geographical area between the Toros (Taurus) Mountains and the Sinai Peninsula and from the Mediterranean Sea eastward into the desert. Following World War I, when separate governments were established for Palestine and Transjordan, Syria usually

was the general name used to designate only the northern part of geographical Syria. After World War II, however, the two independent republics of Syria and Lebanon were established. Syria, therefore, is in modern usage the name of the state located approximately between 32° 25′ and 37° 25′ N. lat. and 35° 50′ and 42° 25′ E. long. It is bounded on the north and northeast by Turkey, on the east and southeast by Iraq, on the south by Jordan, and on the west by Israel, Lebanon, and the Mediterranean Sea. It covers a total area of about 72,000 sq. mi.

## GEOGRAPHICAL FEATURES

**Topography.** Much of Syria is plateau country. East of the Anti-Lebanon Mountains, which parallel the coast, are the plains of Aleppo, Hama, Homs, Damascus, and Hauran, with altitudes of 3,000 ft. or more. They fall off gradually to the north and east to the lowlands bordering the Euphrates River. The Euphrates rises in Turkey and flows southeastward for nearly 400 mi. through Syria before passing into Iraq. Its main Syrian tributary is the Nahr Khabour, which rises in Jezireh and waters much of the cultivated land of that province. The Orontes River flows northward through the plains of Homs and Hama but enters Turkey before emptying into the Mediterranean south of Antakya (Antioch). The south of Syria is a rugged, mountainous region still largely cut off from the main areas of the country. The province of Druz is located here, where the irregular topography has for centuries maintained the independent and local characteristics of the people and their society without significant change. The eastern sections of the provinces of Damascus, Homs, and Euphrates are called the Syrian Desert and this region merges with the Arabian Desert in Iraq and Transjordan to the south.

**Mineral Resources.** In Syria the known mineral resources are scanty and at present quite uneconomical to develop. Rumors of oil deposits in the provinces of Latakia, Euphrates, and Jezireh have circulated, and in 1949 an oil concession was granted to the Syrian-American Oil and Gas Company on the condition that three wildcat rigs be kept in operation continuously. Rich asphalt deposits exist in Latakia and along the Euphrates River and bitumen is found near Damascus. These as yet remain largely undeveloped. Excellent stone quarries are available in all of the provinces but the lack of transportation and their inefficient operation limit use of the stone to the immediate vicinity. Salt is extracted from numerous marshes throughout Syria and can be done in a manner to provide for an export market. Insignificant deposits of coal, iron, copper, lead, and gold have been discovered.

**Climate.** The climate of Syria is varied. Along the Mediterranean coast in Latakia, the winters are mild, with considerable rainfall, and the summers are dry though not excessively hot. In the interior, the plains of Aleppo, Hama, Homs, Damascus, and Hauran have cool, almost cold winters and hot, dry summer days with cool nights. Annual rainfall in this region averages between 10 and 20 in., but irrigation is a necessity since most of the rain falls in autumn and winter. Eastward, the plains merge into the Syrian Desert, where precipitation averages less than 2 in. a year.

**Soil.** About 50 per cent of the land is arable, but only half of the arable land is cultivated. Much of the land is exhausted from excessive use and lack of crop rotation. Water is scarce in most regions. In 1955 a five-year irrigation and farm-development program, eventually to cost $530,000,000, was begun, partially financed by a loan from the International Bank.

## ETHNOLOGY AND POPULATION

**Origins of the People.** Syrians are for the most part Semitic in origin. Throughout historic times and probably in prehistoric periods, Syria, the very center of the Fertile Crescent, has continuously received an influx of people from the eastern desert. Phoenicians, Canaanites, Hebrews, Aramaeans, and Arabs have inhabited various parts of Syria in the past, but the gradual infiltration of desert nomads, individually, by families, or even by whole tribes such as the Tanukhids, Ghassanids, and Taghlibids, has maintained the strong Semitic and Arabian character of the people.

**Language.** When the Aramaean state ruled from Damascus, the language of Syria and even of neighboring regions was Aramaean. Today Turkish and Kurdish are spoken in Jezireh, where a number of refugees from Turkey have settled since 1923. Another dialect, called Syriac, and the Greek tongue survive in Syria, but the language of the country and its people is primarily Arabic. Syrians contend that their Arabic is closer to the classical Arabic than any other form except possibly that spoken in Saudi Arabia.

**Religion.** About 85 per cent of the people of Syria are Moslems, and of these some 85 per cent are of the Sunnite sect. Christians form about 14 per cent of the population, and they are for the most part members of the Greek Orthodox and Armenian churches. Jews and others form less than one per cent of the population.

**Population.** The population of Syria is estimated to be about 3,568,000. At least 75 per cent of the people derive their livelihood from agriculture or from their herds. There are relatively few cities; their 1952 populations were: Aleppo, 380,919; Damascus, 372,708; Homs, 261,904; Hama, 155,671; and Latakia, 105,363.

## GOVERNMENT AND POLITICS

**Administration.** The country has in general followed the French type of republic, except to have a unicameral leg-

EWING GALLOWAY

*A tiny year-around stream waters the small town of Aadra which stands in the desert of southern Syria within the walls of an ancient caravanserai on the old Damascus-Cairo route.*

islature, the Chamber of Deputies, to which members are elected for a four-year term. The practice has been for an assembly to be elected by the people to draft a constitution. The president is the head of the state, and the cabinet, with a prime minister who acts as the executive, is chosen from the members of the Chamber. Theoretically, the president has a five-year term, but thus far no president has had a full term because of the numerous revolts.

**Civil Rights.** In 1949 the vote was extended to women, and more than 10,000 broke many of the traditions of the past and cast ballots for the Constituent Assembly in November of that year. Freedom of speech and the press have been greatly curtailed by the several *coups d'état.* Newspapers have been severely suppressed and various news items withheld.

**Political Parties.** The political parties of Syria are numerous; the strongest in the short history of the republic have been the Independents, the People's Party, the Nationalists, and the Resurrection Arab Socialists. The Communists, although active, have not been able to organize effectively. All parties are essentially nationalist, but they vary in the degree to which they wish to remain Syrian; some advocate a union with Jordan and Iraq to form a Greater Syria. All are hostile to Israel. Some prefer an alliance with Turkey and the West rather than a continuance in the exclusive Arab League.

**Finance.** Taxes in Syria are numerous. The most significant one for state and individual is the tithe which is collected from the produce of most lands. There are taxes on buildings, animals, land, and income as well as a general poll tax. There are many excise taxes and the usual import duties. From time to time, difficulties over the latter have arisen with Lebanon, for normally much of the Syrian external trade passes through Beirut and Tripoli.

**Government Enterprises.** Since water is so vital to the economy, the government has been most concerned with irrigation, which is almost entirely under government control. Various state power enterprises have been established, and early in 1950 a new project was started to harness the Yarmuk River. The government purchased one third of the stock in the company developing the port of Latakia and agreed to underwrite the whole enterprise. The Syrian government refused aid from the United States until 1954, has nationalized electricity, transport, and water, and is determined to use local capital in new developments and industries.

**Armed Forces.** The army, of about 40,000 men, is an important element in Syrian life and politics. All of the recent *coups d'état* were inspired and led by the army. The war in Palestine presented many problems. Although several divisions were deployed in northern Palestine, the Syrian armies were so ineffectual against the Israeli army that the military *coups* were reactions from foreign failure.

**International Relations.** The international position of Syria is exceedingly complex. A member of the Arab League, Syria was definitely opposed to the partition of Palestine and the establishment of Israel. Syria, however, has not been on easy relations with any of its neighbors. Financial and economic problems with Lebanon have led to the closing of that frontier on several occasions. Syria recognized the Arab government in Palestine at Gaza but considered Abdullah's annexation of Arab Palestine to Jordan as a threat to Syrian independence. Conversations with a view to creating a union with Iraq led to a *coup d'état* in 1949; the presence of many Armenians in Aleppo and refugee Turks and Kurds in Jezireh, as well as the award of the province of Alexandretta to Turkey in 1939, has caused much bitterness. Syria has been a member of the Security Council of the United Nations. Its somewhat anti-United States attitude was not the result of pro-Soviet or pro-Communist leanings but was related to the lead taken by the United States in promoting and recognizing Israel.

## ECONOMIC ACTIVITIES

**Agriculture.** In agriculture little fertilizer is used and the land is planted to wheat year after year. About 75 per cent of the cultivated acreage is given over to cereals, the principal ones being wheat, barley, oats, sorghum, corn, sesame, millet, and rice. Wheat, however, accounts for about two thirds of the total cereal production. Under the stimulus of high prices during and immediately after World War II and from the encouragement of the Middle East Supply Council in Cairo, swamp lands in Syria were drained, new areas in Jezireh were brought under cultivation, and new crops were introduced. Syria produces fine tobacco in Latakia, and a great increase has been made in cotton, potatoes, sugar cane, beans, peas, and lentils. In the environs of Damascus there are many apricot orchards, and sheets of dried pulp are a major item of Syrian export. Other agricultural products of importance are silk, olives, citrus fruits, figs, pistachio nuts, and grapes. Sheep and goats are raised abundantly, but very little cattle.

**Industry.** Industry for the most part is in the handicraft stage. In Aleppo, Damascus, Homs, and Hama handicrafts are important, and skill of a high order is attained by many of the artists and artisans. Weaving of cloth and rugs is the most important of these industries, and the finest of silk brocades are made in Syria. Damascus and Aleppo have always been noted for their excellent metalwork in brass, copper, silver, and iron. Only the silk-spinning industry has been organized on a factory basis. The government realizes the lack of many basic industries and plans to utilize local resources more fully. Progress has been made in the production of olive oil, cigarettes, dried fruits, rope, cement, and more recently, sugar and alcohol.

**Commerce.** Every village in Syria has its market, and the exchange of goods is an active and exciting experience. Local products make up the major part of the trade within Syria. The large trading cities are Aleppo, Damascus, Latakia, Homs, and Hama. Soap, olive oil, wheat and wheat flour, and cloth are the chief domestic products. Syria's imports are manufactured goods of every kind—metals, oils, gasoline, and similar products. Since a great deal of the country's trade passes through Lebanon, the port of Latakia is being developed to give more independence to Syria. Exports include cereals, olive oil, soap, animals, fruits, and tobacco. In the main, exports go to Palestine, Iraq, the United States, and France; the imports come from the United States, Great Britain, France, and Italy.

**Banking and Currency.** Until recently, banking in Syria was dominated by the Banque de Syrie et du Liban, which was a French bank with Paris headquarters. Since World War II, French influence has waned and local banks have grown in importance. Much of the banking and moneylending in Syria is controlled by Egyptian bankers. In 1948, when Syria divorced the pound from the franc bloc, Egyptian bankers visited Damascus to discuss and arrange for the exchange backing of the independent Syrian pound, the monetary unit established in common with Lebanon. In September 1955 it was worth approximately 25 cents in United States currency. The financial and economic position of Syria in the period following World War II has been rendered more difficult by the serious inflation that the war brought.

**Transportation.** In general, transportation remains in a backward condition. Damascus is connected by rail, through Lebanon, with Beirut, and then with Homs, Hama, and Aleppo, and by extensions with all the neighboring countries. Motor roads fan out from Damascus to the major cities and Palestine; the famous automobile road from Baghdad has its terminus in Damascus. Most transportation, however, is over poor wagon roads or caravan trails. In 1946 the Syrian Aviation Company began service between Damascus and Baghdad, Cairo, and Jidda. International airlines, such as Air France, KLM (Dutch), the Scandinavian, the British Overseas Aviation Corporation, and Pan American World Airways, have scheduled stops at Damascus.

## SOCIAL AND CULTURAL ACTIVITIES

**Education.** Education has not yet become available to all. Many Christian sects have their own schools and advanced institutions, so that frequently one finds only Moslems attending the public schools. There is an American school in Damascus and an American college in Aleppo, the latter being supported and operated by the American Board for Foreign Missions of the Congregational Church. Many children of the wealthier families study abroad. Elementary school is free and compulsory, but secondary schools are lacking. In 1947 an Institute of Technology was opened at Aleppo. There is a new Syrian State University at Damascus, specializing in law, pharmacy, medicine, and political science. However, 64 per cent of Syria's population is illiterate.

**Social Conditions.** In every aspect of the living conditions in Syria the standards are low. Fuel is scarce; consequently dung is frequently burned, depriving the fields of much needed fertilizers. Agricultural methods are outmoded and the yield is poor. Since the economy of Syria is almost entirely dependent upon this livelihood, the standard of living does not approach western standards. Nevertheless, there has been a rapid influx of western methods and ideas since 1940. Upper and middle class Syrians quite openly have adopted many Western ways. French and English are known, if not always spoken, by the educated classes. Many women in Damascus appear in mixed society no longer wearing the veil. As these changes continue, the customs and habits of the masses are affected.

## HISTORY

Prior to the establishment of separate mandates for Palestine, Lebanon, and Syria following World War I, that part of the Fertile Crescent west of the Euphrates River had historically formed one political, economic, and geographic division, usually termed Syria.

**Early Peoples and Cultures.** In the earliest period of

history Syria was the land where the civilizations of Mesopotamia and the Nile met and were fused. Dominated usually by one or the other, the Syrians, a mixture of Mediterranean and alpine peoples speaking a Semitic tongue, assimilated and transformed these civilizations into one of their own. However, repeated waves of immigration, mainly from the eastern desert, maintained the Semitic character of Syrian civilization. Phoenicians, Canaanites, Aramaeans, and Hebrews migrated into Syria in the third and second millenniums B.C., and at different times created independent governments. The Phoenicians extended their commercial empire to embrace much of the Mediterranean area, the Aramaeans developed their trade overland to the Indian Ocean, and the Hebrews brought to the world a greater knowledge of God; but, ordinarily, ancient Syria was only a province in an empire ruled by Egyptians, Babylonians, Assyrians, Hittites, or Persians.

Following conquest by Alexander the Great in the fourth century B.C., Syria became a part of the Greek world under the Seleucid emperors and was Hellenized to such an extent that it rivaled Asia Minor and Alexandrian Egypt as a center of Greek culture. Toward the end of the Seleucid era such local principalities as the re-established Hebrew Kingdom and that of the Maccabees appeared. In the first century B.C., however, Syria fell to Rome, to remain under Roman and Byzantine rule until the advent of Islam. For seven hundred years Syria was an integral and influential part of the Mediterranean world, and Syrians were found in every part of the empire as merchants, generals, scholars, lawyers, poets, churchmen, and bureaucrats. At least two Syrians became Roman emperors. In the development and spread of Christianity Syria was important. Antioch and Edessa were centers where many Christian doctrines were formulated and where the Nestorian, Monophysite, and Monothelete sects began.

*The giant columns of the Temple of Jupiter are among the ruins of an ancient city which lies west of the modern town of Baalbek.*

PHILIP GENDREAU

Nevertheless, as the Mediterranean area became less unified, Syria entered a period of political and economic decline. In the third century A.D. the kingdom of Palmyra in the Syrian Desert appeared, but the strength of the empire was still sufficient to meet and crush this threat of desert nomads. Moreover, the administration from Constantinople grew exceedingly oppressive and decadent, and under the burden of Justinian's wars the economic situation intensified popular discontent. To this situation was added the Byzantine policy of persecuting the many Syrian sects not conforming with the Eastern Orthodox Church and of using Syria as a battleground when the neglected defenses of the empire invited a series of wars between the Sassanid and Byzantine empires.

**First Moslem Period.** Thus Islam met little local resistance in Syria. First invaded in 633, by 640 Syria had become a part of the Moslem Empire. However, the Arabization of Syria did not begin with the conquest, since desert nomads had been infiltrating the country for two thousand years. Conversion to Islam was slow and voluntary. Christians and Jews were definitely outside the Moslem community and did not enjoy full civil rights, but they were granted a greater degree of religious tolerance than had been enjoyed under Byzantine rule, and were allowed to keep their property and manage their own communities according to their ancient customs and laws. In less than a generation the wealth, industry, and size of the Syrian cities had shifted the center of the Moslem Empire from Mecca and Medina to Damascus. From 661, when Muawiyah, the governor of Syria, proclaimed himself caliph, until 750 Damascus was the seat of the Ommiad dynasty and the center of the Moslem world. The Ommiad Empire was administered by Syrians—Christian and Moslem alike—and its wars against the Byzantine emperors were waged by Syrian soldiers. Under the Ommiads, the caliphate remained wholly Arab and Moslem, and Arabic became the language of government in Syria, replacing Greek and Aramaic. However, the Hellenistic civilization of Syria prevailed, since the Arabs succumbed gradually to the culture, the social organization, and the political systems which they found. The Arabs "gained in technical mastery and maturity of the intellect; they lost the pristine simplicity of their faith and way of life."

Sectional, religious, and dynastic controversies in the eighth century shattered the glory of Damascus and Syria as the Abbasside caliphs established their chief residence in Baghdad. Syria's population decreased and its prosperity waned. During the subsequent three centuries of depression many changes occurred in the character and culture of Syria. Individual Christians and their communities found existence more difficult to endure; conversions to Islam were numerous, and the Arabic tongue became almost universal. Whole Christian communities were moved to mountainous regions for safety, especially during periods when weak caliphs ruled in Baghdad.

With the decay of the Abbasside government, Syria's north frontier became more vulnerable to Byzantine attacks. Along this uneasy line developed local principalities, Moslem and/or Christian in civilization, which looked to Baghdad or Constantinople for friendship, depending upon which was stronger or more generous in its subsidy. Heresy flourished and often was more popular than orthodoxy. Shiitism was popular and was the source of the extreme Alawite and Druse sects, which originated in this period. In addition, many movements were imported from Persia, Mesopotamia, and Egypt; these were built around various initiatory secret societies with revolutionary political, social, religious, and philosophical views.

The intellectual and emotional freedom which gave rise to this heterodox situation in northern Syria also created a condition that stimulated poets and authors. At the Hamdanid court at Aleppo, the philosopher al-Farabi (Alfarabius) composed psychological, political, and metaphysical works, and wrote treatises on Plato and Aristotle and books on medicine, mathematics, occult science, and music. He is considered the greatest music theorist among the Arabs. A contemporary at the Hamdanid court was the great Arab anthologist abu-al-Faraj al-Isfahani. His *Book of Songs* is called by the Arabs "the final resource of the student of belles-lettres." However, the two greatest cultural figures of this era in Syria were the poets abu-al-Ala al-Maarri and al-Mutanabbi. The former is particularly well known for his *Treatise on Forgiveness,* which some scholars assert influenced Dante in his composition of the *Divine Comedy,* and many quatrains of which had a strong influence upon the poetry of Omar Khayyām. Al-Mutanabbi was the poet laureate at the Hamdanid court at Aleppo, and his flowery style makes him still the most popular poet of the Arab world.

**Turkish Conquest.** This Syrian renaissance of the tenth and early eleventh centuries was ended rather abruptly with the conquest of Syria by the Seljuk Turks, who entered the country from Asia Minor and northern Mesopotamia. These invaders at first were a minor branch of the great Seljuk state in Persia, but, like their cousins at Konya, the Syrian Seljuks soon severed all outside allegiances and then split into two states, Damascus and Aleppo. The Seljuks, however, never penetrated into southern Syria, which remained under the control of such local families as the Tanukhids or recognized the suzerainty of the Egyptian Fatimids. At the end of the eleventh century this fragmentation of Syria was further complicated by the arrival of the Crusaders from western Europe, who ushered in a new epoch in the history of the Middle East.

**The Crusades.** In the last years of the eleventh century the Crusaders, mostly French, invaded Syria from Asia Minor and from the sea, conquering all of the coastal region and some of the interior. The feudal states of Edessa, Antioch, and Tripoli were organized by these European lords and knights, whose power and hold were maintained by a steady succession of reinforcements. Fully as important for the influence of Syria upon the west and for Syrian prosperity were the many Italian merchants and shippers who came with the Crusaders and established Frankish quarters in every coastal city of Syria, and in many of the cities of the interior. Sidon, Acre, Tyre, Aleppo, Antioch, Tripoli, Beirut, and many others came to have quarters inhabited by Pisans, Genoese, and other Italians, where vast quantities of pepper, sugar, and other eastern articles were gathered for shipment to western Europe. Crusaders who remained in Syria as long as five or ten years showed a marked tendency to mingle with the native population and to adopt much of their civilization. Subsequently most of the adaptations were transferred in one way or another to their western homes, and thus Syria played an important role in raising the cultural level of Europe. Syrian Christians were urged to submit to the papacy, a step which the Maronite Church took at this time. Moslems were treated with tolerance, although warfare between invader and inhabitant was intermittent from the first invasion in 1097 until 1291, when Acre, the last fortress of the Crusaders, fell.

Even at their best the crusaders never held more than a tenuous grasp on a narrow strip of Syrian coastland. The Moslem sway in Damascus was never threatened. When Zangi, the Turkish governor of Mosul, razed the city of Edessa, the Second Crusade was instigated, and in 1187 the fall of Jerusalem to the forces of the great Saladin precipitated the Third Crusade of Richard I of England, Philip Augustus, and Frederick Barbarossa of Germany. These and other crusades failed in their general purposes, leaving the remaining Crusaders in Syria to shift for themselves. Upon the death of Saladin, however, the Moslems were so divided that the remnant Christian principalities were able to hold on until 1291. In this period the Mongol invaders under Hulagu swept over Syria, massacring 50,000 at Aleppo and destroying many churches and mosques in Damascus. Stopped in 1260 by Baybars I, Mameluke sultan of Egypt, in a battle near the Palestinian coast, the Mongol horde retired to inner Asia, leaving Syria broken and depressed.

**Mameluke Rule.** Until 1516, Syria was ruled, except for brief interludes, by the Egyptian Mamelukes. This was a period of unrest, economic difficulties, population decline, poverty, and political and social decay. In the late thirteenth century the rebellion of the Druses and Shiites was ruthlessly suppressed by the Mamelukes, and in 1401 Aleppo and Damascus again were sacked, this time by Tamerlane, who carried off their artisans to his capital, Samarkand. The final blow to medieval life in Syria came from the Portuguese rounding of Africa, with its subsequent shifting of the trade routes between India and Europe to bypass the Middle East entirely. With the Syrian and Egyptian entrepots almost empty of oriental goods, political and economic chaos developed to such an extent that these areas fell easily and quickly in 1516-1517 to the Ottomans under Sultan Selim I.

**Ottoman Period.** For the next four hundred years Syria was a part of the Ottoman Empire. The first three centuries were, in general, periods of stagnation. The Turks divided the area at first into three provinces: Tripoli, Aleppo, and Damascus, the latter embracing all of the land south of that city to the borders of Egypt. Later, other provinces were created, such as those of Saida and Acre. Each of these provinces was governed by a pasha who was directly responsible to the government in Istanbul, so that Syria ceased to exist as a single state. The economic decline which had begun under the Mamelukes continued under the Ottomans, although taxes imposed by Turkey were less than formerly. Aleppo and Beirut became the main trading centers, and colonies of Europeans enjoying special privileges under the capitulations were established in many Syrian cities; most of the trade with Europe passed through their hands. In addition to these merchants, many missionaries, especially Roman Catholics—Franciscans and Jesuits—came to work among the Christians of Syria. They gave the area its first modern schools and were the first to succeed in bringing western ideas into the country to such a degree as to have a real influence upon Syrian society. However, since Syria did not attract Turkish settlers, the Turkish pashas frequently were unable to exercise any authority beyond the walls of the garrison city. This was especially true after the death of Suleiman the Magnificent in 1566, when power was held by Syrian feudal families, which ruled according to the ancient laws and customs of the land. Many of the families, such as the Maani and the Shihabi, were independent of the Ottoman government, except that formal respects were paid in the mosques to the sultan, who had taken the title caliph. Many of these families carried on feuds among themselves, and as a result of one of these conflicts the area southeast of Damascus called Jebel ed Druz was settled by a defeated Druse faction. At the end of this period much of Syria fell into the hands of Jazzar, pasha of Acre, who oppressed the people relentlessly until 1804.

Toward the end of the eighteenth century a radical influ-

ence began to permeate Syrian society. European powers, finding the Ottoman Empire only a shadow of its former glory, sought to establish spheres of influence. France cultivated the Maronites and other Catholics, the Russian tsars asserted the right of protection over Greek Orthodox Christians in Syria, and the British proffered their friendship to the Druses. Each of these powers thus interfered in the domestic affairs of Syria and each in its way aided in bringing European ideas of sovereignty to the Syrian people. The first great shock to the old order appeared to come in 1798-1799, when the French under Napoleon came to Egypt and marched up the Syrian coast. But, with the aid of the English fleet, Jazzar Pasha held Napoleon long enough at Acre to induce him to abandon the project and return to France. Thus, for the first three decades of the nineteenth century, the old order prevailed and rule from Constantinople was virtually nonexistent. Tax farmers, feudal lords, and predatory Bedouins made the life of the settled peasant almost unbearable, and the flow of commerce through the principal cities was the only evidence of prosperity.

In 1833, however, Mehemet Ali of Egypt compelled his nominal suzerain, the Ottoman sultan, to permit Syria's annexation to Egypt. The next six years under the rule of Ibrahim Pasha, Mehemet Ali's son or adopted son, began the modern era for Syria. Law and order prevailed, government schools were founded, and agriculture and trade were promoted. Ibrahim's government originally was popular, but the establishment of various state trade monopolies, heavy taxation, forced labor, and disarmament, as well as political and social discrimination against the important local families, led to considerable friction. The great powers of Europe came to look upon Mehemet Ali's proprietorship as a menace to their interests and were particularly irked by his commercial policies which discriminated against them. Thus, in 1839, when trouble arose between Turkey and Mehemet Ali, the great powers, except France, intervened to force Mehemet Ali to submit and evacuate Syria. This was done by diplomacy and by sending arms to the Druses and Maronites, who rose in revolt and drove Ibrahim back to Egypt. Nevertheless, a large portion of Ibrahim's accomplishment with respect to government, trade, agriculture, education, and westernization remained. Throughout the nineteenth century the great powers from time to time pressed the Turkish government to enact reforms of various kinds, but most of these were inadequately executed. The sultan, however, was strengthened by the creation of an army along European lines, so that the Ottoman government succeeded in curbing local feudalism in certain areas in northern Syria. Although the Pilgrims' Railway was built from Damascus to Medina, and other public works were begun under Abdul-Hamid II, Syria was far from prosperous and was very discontented. Many intellectuals subscribed to pan-Islamism and others to the Young Turks' Committee of Union and Progress, but after 1908 most Arabs realized that Arab interests were wholly disregarded and that Arab nationalist aspirations would only be served by their own political endeavors.

**World War I.** In 1914, when the Ottoman Empire entered World War I, negotiations were opened between the British and Grand Sherif Husein ibn-Ali of Mecca with regard to Arab participation in the war on the side of the Allies, on the basis that Arab independence would be recognized upon the successful termination of the war. Husein was promised that Syria, except for lands west of Damascus and Aleppo but including Palestine, would be held as an Arab independent state. In 1916, however, France and Great Britain signed the Sykes-Picot Agreement, which, in effect, gave the Syrian coastal area north of Acre to France, and the territory south of Acre and including Palestine and Transjordan to the British, leaving only the interior of north Syria to be independent. In 1917 the Balfour Declaration pledging British support for "the establishment in Palestine of a national home for the Jewish people," in addition to the Bolshevik disclosure of the Sykes-Picot arrangements, gave the Arabs considerable grounds for questioning Allied sincerity, although the British repeatedly in 1917 and 1918 promised recognition of Arab national existence and President Woodrow Wilson in his Fourteen Points held that the Arabs should be assured an "unmolested opportunity of autonomous development." In spite of Allied duplicity, the Arabs revolted against the Turks and aided materially in Marshal Allenby's capture of Damascus in 1918. Thereupon Syria was occupied by British, French, and Arab troops.

**Under French Mandate.** At the Paris Peace Conference violent disagreement arose over the disposition of Syria. President Wilson sent the King-Crane Commission to Syria to investigate, but its recommendation to create a Syrian independent constitutional monarchy under King Faisal, son of Husein ibn-Ali, was ignored. At the San Remo Conference, Syria was assigned to France as a mandate and Palestine and Transjordan were cut off and placed under British administration. Nevertheless, Faisal accepted the crown of Syria from a congress of notables meeting at Damascus in 1920 and, although agreeing to recognize the French mandate, he would not accept all the French demands. Thereupon French troops fought their way into Damascus, provoking the hatred of the Syrians. French rule in Syria began in an atmosphere charged with bitterness, suspicion, and resentment.

Under the mandate, a French high commissioner and a staff of French officials directed the policies of the state. In accordance with the terms of the mandate to France, organic laws were drafted for the establishment of local government, but Syria was divided into several states: Lebanon, Latakia (the Alawite state), Jebel ed Druz, and Syria. Latakia and Jebel ed Druz, however, were merged with Syria in 1936. Representative councils were chosen and a semblance of local government initiated. Unrest in Syria appeared almost immediately. High commissioners and administrators were changed too frequently, a Syrian federation was created and quickly dissolved, and the general instability of French policy led to forming the People's Party which advocated the independence of Syria and the union of the Arab world. In 1925 a rebellion occurred, first in Jebel ed Druz, and a sizable French force was defeated. The French quelled the outbreak in 1926, although Damascus was twice bombarded. As a result, Jebel ed Druz was placed under strict surveillance of a French governor, but Syria was permitted to elect a representative council. Ahmad Nami became the head of the first ministry.

In 1928 a constituent assembly was elected and the state of siege lifted. The assembly, under Hashim al-Atassi, drafted a constitution which proved unacceptable to France, and in 1930 the assembly was dissolved. France prepared a constitution for Syria, and in 1932 called for the election of a chamber of deputies, which, it was hoped, would arrange a Franco-Syrian treaty and the termination of the mandate. The treaty draft was placed before the chamber, but nationalist parties made acceptance impossible, so that the high commissioner dismissed the chamber and authorized the president to govern by decree. This situation prevailed until 1936, although Syrian discontent and national feeling grew apace. Early in 1936 a general strike occurred in Damascus

as a protest at the failure of France to grant Syrian independence. Leaders were invited to Paris to negotiate a Franco-Syrian treaty, which was signed Sept. 9, 1936. The treaty, allowing special privileges to France for twenty-five years, granted freedom whenever Syria was admitted to the League of Nations. A new Syrian chamber was elected, and Hashim al-Atassi was elected president of the republic. The treaty was approved and formally signed Dec. 22, 1936. Meanwhile, Latakia and Jebel ed Druz were annexed to Syria. The French government, however, failed to ratify the treaty, and this fact, together with concern over Palestine, the loss of Alexandretta to Turkey, and the administrative difficulties of the Syrian government, led to the collapse of this experiment of 1936. In 1939 the constitution of the republic was suspended, and the high commissioner appointed a provisional government.

**Syrian Independence.** Upon the outbreak of World War II in 1939, the country's prominent political figures declared their loyalty to France and the democracies, although most Syrians showed little interest. The capitulation of France to Germany in 1940 did not change the status of Syria until April 1941, when France withdrew from the League of Nations. Syria at this juncture considered the mandate as terminated, but no steps were taken to change the organic political structure until the occupation of Syria by British and Free French troops in July 1941 and the declaration of Syrian freedom and independence. Sheik Taj ad-Din al-Hasani, of Damascus, was recognized by the Free French as president of the Syrian republic, and in 1942 the British sent General Sir Edward Spears as British minister to the Syrian republic. General Spears controlled Syria until the end of World War II, since the French showed no desire either to transfer power to the Syrian government or to establish valid Syrian independence. Nevertheless, new elections were held in July 1943, the national bloc winning a decisive victory. Various difficulties with respect to finance, inflation, scarcity of goods, foreign trade, transportation of oil, irrigation, and administration confronted the new state. With full and complete recognition in 1944 by the United States and the U.S.S.R., Syrian independence was assured.

Since the formation in 1944 of the Arab League, Syria has taken an active part in its affairs. Syria is a member of the United Nations and has taken part in its deliberations. Syria served as a temporary member of the Security Council and the Committee on Trusteeship, and the Syrian delegate won respect by his skill in serving as chairman of the Council.

The partition of Palestine by the United Nations sharpened all of the problems confronting the Syrian republic and added new ones to trouble the leaders of the government. Although agreements had been made with the Iraq Petroleum Company and the Trans Arabian Pipeline Company for the right of transporting oil across Syria, the work of the latter was halted when the United States advocated the partition of Palestine. When fighting began in Palestine, tension mounted in Syria. The legations of France and the United States in Damascus were stoned and Communist Party headquarters was burned and the party outlawed. In December 1947 a draft was formally instituted and Druse offered to recruit 10,000 men for war in Palestine. The Syrian government, however, greatly irritated by the pronouncements of King Abdullah of Transjordan in calling for the establishment of a Greater Syria, countered with an invitation to Transjordan to rejoin the Syrian republic. In October 1948 it recognized the Arab government for Palestine at Gaza.

Unfortunately, Syrian politics have been very unstable. Already two constitutions have been drafted and adopted since 1945, and no president has served his legal term, not even Adeeb Shishekly, the strong man of Syria, who himself directed several *coups d'état.* The army overthrew most of the governments, but the Arab Suicide Redemption Falange was responsible for murders and assassination attempts between 1948 and 1950. The instability in government was partially due to intense national feelings that gripped the nation in relation to some of the issues. Military defeats by Israeli forces, trade and customs differences with Lebanon, reorientation of diplomatic policy toward the West and Turkey, have created dissension and strife. Nevertheless, after delays, in indication of protest, the world's biggest pipeline, extending from Saudi Arabia to Saida (1,069 mi.), was completed in 1950; the pipeline from Kirkuk oilfields in Iraq to Banias, 556 mi., was completed in 1952. After several years of bickering Jordan and Syria established diplomatic relations in 1951 and signed a friendship pact; a similar pact was signed with Iran in 1953; in 1955 Syria was invited to join the Turkey-Iraq friendship and defense pact. Even though Syria at one time refused aid under the United States Point Four Program, it applied for and received monetary aid from the International Bank in 1955, has received American military aid on several occasions, and in 1954, after an initial rebuff, accepted the United States plan and aid for the diversion of water from the Hule swamp area, with the purpose of developing electric power for Jordan, Israel, and Syria. S. N. F. and H. C. K.

**SYRIAC LITERATURE.** Syriac, originally the Aramaesic dialect spoken in Edessa, Northern Mesopotamia, whence Christianity spread over the whole of the Near East, became important only in connection with and in dependence upon the development of the Syrian Church. Most works composed in it deal, therefore, with religious subjects; their study belongs to church history and presents none or few features of artistic significance. With the earliest manifestations of Syriac literature, Greek influence was prominent, and many translations from the Greek were made of works dealing not only with religion but also with philosophy and science; many of these were later translated into Arabic, thus securing the survival of Greek thought during the Middle Ages. No interest was ever shown in the poetic achievements of the Greeks, although Theophilos of Edessa (died A.D. 785) translated Homer into Syriac.

Very little, indeed, was ever written in Syriac for the sake of entertainment. However, some Syrian authors were not devoid of a certain amount of artistry. *The Book of the Laws of the Countries,* a dialogue after Greek patterns, in which Bardesanes (c.154-c.223) refutes the tenets of the astrologers, is one of the earliest products of Syriac literature and contains some valuable passages. Bardesanes' son, Harmonios, composed hymns in which he expressed in poetry the gnostic system for which his father is held responsible, and in the scanty fragments that have survived we find real poetic inspiration. Another gnostic poem, *The Hymn of the Soul,* embodied in the apocryphal Acts of St. Thomas, is worthy of appreciation. The greatest personality in the ancient Syrian Church, St. Ephraem (c. 306-373) composed metrical hymns (*madrâshê* and *soghyâthâ*) and homilies (*mêmrê*) in order to counteract the impact of Harmonios' heretical poems upon the popular mind. The style and the meters (based on the number of syllables) introduced by St. Ephraem remained standard in later church literature; outstanding in this field were Isaac of Antioch (fifth century), of the Nestorian branch of the Syrian church, and Jacob of Serugh (sixth century), of the Jacobite branch, who was responsible, for instance, for a vivid descrip-

tion of the invasions of the Huns. Homily and theological polemics, generally in the form of epistles or short tracts, afforded some gifted authors the opportunity to develop an elegant and precise prose style: the best among them, especially for the vigor of his eloquence, is Philoxenus of Mabbogh (sixth century).

A historical novel, the *Romance of Julian the Apostate,* anonymously written about the same time, may be reckoned among belles-lettres, although its purpose is chiefly religious; two other outstanding literary products, more or less contemporary with *Julian,* are translations: the *Legend of Alexander the Great,* from the Greek; and the fable book known as *Kalilag and Damnag* (which became famous under the Arabic title *Kalîla and Dimna,* from the Pahlavi or Middle Persian, and ultimately from the Indian *Panchatantra*). Records of the deeds and acts of saints and especially of martyrs (those who suffered death under the Sassanid kings of Persia are particularly important) not only are valuable as historical documents but often are of considerable artistic achievement through the immediate appeal of their candid and unsophisticated style; this is also true of the early large collections of lives of monks and hermits, the most famous of which are the *History of Superiors* by Thomas of Marga and the *Book of Chastity* by Îshô'denah (both Nestorians, from the ninth century).

After the Arabian conquests in the seventh century, Syriac gradually ceased to be spoken, and Arabic took its place. Although Syriac continued to be used as a learned language, its estrangement from actual life proved fatal to the previous high aesthetic standard of literature. A short-lived rebirth in the thirteenth and fourteenth centuries was chiefly due to the personal action of two men, Bar-Hebraeus (1226-1286) in the Jacobite area and 'Abdîshô' (died 1318) in the Nestorian: both were entirely under the spell of Arabic culture; the latter, in order to show that Syriac was by no means inferior to Arabic as far as the richness of its vocabulary was concerned, vied with the refinements and niceties of Arabic rhymed prose in his *Paradise of Eden,* which is as admirable for its elaborate skill as it is poor in its artistic content. The report on a mission to the Pope and the King of France with which a dignitary of the Nestorian Church, Yahballâhâ, was entrusted by a Tatar sovereign at the end of the thirteenth century, is an amusing and skillful work. G. L. D. V.

**SYRIAN ARCHITECTURE,** in general, the architecture of Syria throughout all of its history. The term is used more specifically, however, to designate the monuments built in the Hellenistic, Roman, and Early Christian periods (third century B.C. to the seventh century of the Christian Era). No extensive Hellenistic remains survive prior to the Roman period (first century B.C. to the fourth century of the Christian Era), but Hellenistic influence pervades much of the provincial Roman work, and is present also in buildings constructed directly under imperial supervision, such as the great temple complex at Baalbek.

**Characteristics.** Several features, the result of the fusion of Hellenistic and native qualities, distinguish the architecture of the Hellenistic and Roman periods from contemporary work in other parts of the Mediterranean world. Stone is the chief material, basalt in the south and limestone in the north, and immense blocks, at times reaching sixty feet in length, are used throughout all parts of the buildings. In the north, where wood seems to have been plentiful, the post and lintel system supporting a wooden gable roof appears. In the south, however, where wood was scarcer, stone was used not only for roofing but also in many cases for the framework of doors and windows. To support the stone roofs, transverse arches springing from low, heavy piers were thrown across the rooms. The space between the crown of the arches and the side walls was filled up level with the crowns, and long slabs were laid from the side walls to the central line of support. In buildings of two or more stories the same method was used to carry the intervening floors. Lintels of doors and windows frequently had a semicircle cut in them above the opening which they spanned, producing what is called an arcuated lintel. Columns are usually unfluted, although fluted ones are found at Palmyra.

An outstanding characteristic, found on the façade of structures, is the arching of the entire entablature over the central intercolumniation which is wider than the others. This arching appears as early as the end of the first century B.C. in the temple of Dushara at Sî, and continues in use until the end of the Roman period. Examples may be seen in the west temple at 'Atîl (A.D. 151), the octagonal court at Baalbek (first and second centuries), and in the fragment of a Roman gate at Damascus. Two other typically Syrian features are the use of the niche as wall decoration, found at Palmyra, Jerash, Baalbek, 'Atîl, and elsewhere, and the development in the temple cella of an adytum (sanctuary) with a chamber on either side. Examples may be seen in southern Syria in the Tychaion at iṣ-Ṣanamên, the temple of Slêm, and the Serâyā and temple of Zeus at Ḳanawât.

**Carvings.** Rich carvings and moldings decorate the buildings of the pagan period, especially in southern Syria, in a style modeled on the Hellenistic. All three orders appear, the Corinthian most frequently. The acanthus leaf is usually the crisp, thorny *acanthus spinosus* of the Greeks, but the softer, rounded *acanthus mollis* of the Romans also appears. At Baalbek, both types are found side by side. Architraves commonly have a meander design, friezes are carved with scrolls of leaves and flowers, and pilasters carry rinceaux or arabesques in vine-leaf or acanthus patterns. The individual plants are naturalistically treated for the most part, but the design as a whole is conventionally arranged. At first the plant forms are handled plastically, but in the late second and third centuries the edges are more deeply undercut and an interest in contrasts of light and shade results. The coloristic manner so characteristic of later Byzantine work appears early in Syria.

**Secular Buildings.** Surviving ruins of cities and towns with temples, civic buildings, baths, inns, private dwellings of all kinds, and colonnaded streets attest the vigor and activity of Syrian builders during the Hellenistic and Roman eras.

**Religious Buildings.** No break exists between the pagan architecture and that of the Early Christian period (the fourth to seventh centuries). Churches take the place of temples, monastery construction begins in the fifth century and continues thereafter, and many of the varieties of secular buildings found in the previous ages are also to be found in the Christian cities and towns. The most extensive, and perhaps most interesting, remains of Early Christian architecture in Syria are the religious buildings, however, and the features they reveal are present also in the secular monuments.

The form of the churches is influenced by pagan antecedents. This influence is especially noticeable in the south, where both religious and civil monuments served as prototypes. Basalt was still the main material, and the transverse arch supporting a stone roof continued in use. In the north, closer to Hellenism, the most typical church type was the

three-aisled basilica with longitudinal supports, columns, and later piers, carrying architraves or arches. The building stone was limestone, laid dry, and the roofs were generally of wood, gabled and ending in a decorative pediment reminiscent of the Greek temple type.

**Ornamentation.** Ornament is the most distinguishing characteristic of Syrian Christian architecture. The northern monuments are more highly decorated than those of the south, where the interest in decoration decreased considerably from the fourth to the sixth century. In the north, in the fourth century, there was a marked reaction against Roman and Greek styles of ornament, and native forms were popular, such as ornamental and symbolic disks, cusped moldings around door frames, spiral terminations of window and door moldings, and geometric and foliate patterns treated in a flat, almost incised fashion with much stylization. In the sixth century, the reappearance of many Hellenistic and Roman motives gives the impression of a classic revival. Columns applied to the exterior walls, cornices with modillions or with dentils, molded string courses, details of capitals and friezes, all betray their pagan origin. These features may be seen in varying degree in the famous church of St. Simeon Stylites at Ḳal'at Sem'ân, at Ḳalb Lauzeh, at Dâr Ḳîtâ, and many other locations.

With the Arab and Moslem conquests in the early seventh century, Syrian architecture as a creative, vital force comes to an end. During its existence, however, it exercised a profound influence on Roman and Byzantine architecture.

J. M. H.

**SYRIAN DESERT.** *See* Arabian Desert.

**SYRINGA** [sɪrɪ′ŋgə], a name widely and erroneously given to the genus *Philadelphus,* shrubs of the saxifrage family. The proper common name of the genus is mock orange, for *Syringa* is the botanical name for lilac. About 40 species of *Philadelphus* are grown in the north temperate regions, mostly in the United States and Mexico. The shrubs are erect and vary in size from 6 ft. to occasionally 30 ft. or more; they have opposite simple leaves. The flower is usually white, and the supposed resemblance to an orange gives the shrub the common name mock orange. The best-known mock orange is the European *P. coronarius.* It has fragrant, cream-white flowers, and in a small way has escaped from cultivation and has naturalized itself in the eastern states.

Most of the species native to the United States, found in the South and on the West Coast, are without the fragrance of this European species, but some of the garden hybrids are extremely fragrant and have both single and double flowers. *See also* Lilac.

**SYRINX** [sɪ′rɪŋks], in Greek mythology, a beautiful nymph beloved by Pan. She fled from him and, calling upon the nymphs for aid, was metamorphosed into a bed of reeds. Pan took reeds of unequal length from this bed and made from them the first Pan pipe, which he named syrinx in honor of the nymph.

G. E. D.

**SYROS.** *See* Siros.

**SYRTIS** [sɜ′rtɪs], two gulfs on the north coast of Africa, known in ancient times as Syrtis Major and Syrtis Minor, now known as the Gulf of Sidra and Gulf of Gabés.

G. E. D.

**SYZRAN** [sɪ′srəny], a commercial town in the Kuybyshev Region of the Russian Soviet Federated Socialist Republic, in the western Soviet Union, about 80 mi. west of Kuybyshev on the Syzran River, near the Volga. It originated in 1683 as a fort against the Tatars and Circassians and became an important center for grain trade. Later, numerous manufacturing plants sprang up in the town. Oil production began near by in 1937. Syzran is an important rail junction and has a port on the Volga. There is considerable transshipment of grain from the lower Volga for points to the northwest. Manufactures include leather goods, lumber, prepared foods, textiles, clothing, tobacco products, bricks, and distilled spirits. Pop. (est. 1950), 160,000.

C. C. H.

PHILIP GENDREAU

*The elaborate grillwork and carved arches of this ancient gateway at Beirut are excellent examples of Syrian architecture.*

**SZCZECIN** or **STETTIN** [shtshɛtsi′n, shteti′n], a Polish port city, in the former German province of Pomerania, located on both banks of the Oder River, about 285 mi. northwest of Warsaw, 80 mi. northeast of Berlin, 30 mi. from the Baltic Sea. Originally settled by Slavs, by the twelfth century the city was the largest in Pomerania, and from the twelfth to the seventeenth centuries it was the residence of the dukes of Pomerania; in 1360 it became a member of the Hanseatic League. The city was under Swedish control twice prior to its passing to Brandenburg in 1678 and finally to Prussia in 1720. Stettin, always a leading port and trade center, was the chief Baltic port for Berlin, with which it was connected by a ship canal. During World War II it was subjected to frequent and severe bombing raids in 1944 and 1945, and its harbor facilities and large shipyards were badly damaged. On Apr. 26, 1945, after a long siege and battle during which this important port was further devastated, the city was taken by Soviet forces. At the conclusion of the war Stettin was awarded to Poland, and its name was changed to Szczecin. Pop. 1946, 140,000.

S. D. M.

**SZÉCHENYI, COUNT ISTVAN** [se′tshɛnyɪ] (1791-1860), Hungarian statesman and writer, was born in Vienna, Sept. 21, 1791. Growing up in Vienna, he studied with Hungarian tutors. He fought through the Napoleonic wars, and between 1815 and 1822 traveled through western Europe, principally England, studying economic, social, and political conditions. He first attracted public notice by donating £5,000 for the creation of an Academy of Sciences in Hungary, in 1825, and he also founded a National Casino. In his first book, *A Hitel* (1830) ("Credit"), and *Stadium* (1833) he pointed out his country's ills—the feudal and antiquated farm system, stagnation in trade and com-

merce, lack of credit, backwardness of constitution. He demanded the elimination of serfdom and the abrogation of tax exemption of the nobility.

From 1830 to 1840 Széchenyi took the initiative in plans to make the Danube navigable, introducing the steamboat, and being instrumental in the building of roads, the bridging of the Danube, and the building of the National Theatre. He hoped to lift his nation out of economic and social backwardness and lead it toward independence. He was active in making proposals, criticizing others, and defending himself in numberless publications. Lajos Kossuth called him "the greatest Hungarian," but politically his liberalism was more and more outstripped by Kossuth's revolutionary spirit.

After the Revolution of 1848, Széchenyi became a member of the first responsible Hungarian Government, only to resign when an armed clash with Austria impended. He suffered a breakdown and was moved to a sanitarium at Döbling. When he regained his faculties in the early 1850's, his satirical articles against absolutism appeared often in Hungary under assumed names or were published abroad. Fearing to lose his reason, Széchenyi took his life on Apr. 8, 1860, in the asylum at Döbling near Vienna. His works on economic, financial, political and social subjects were republished collectively after his death. L. A. V.

**SZECHWAN** [sʌ′tshwɑ′n], a province in central China, on the upper reaches of the Yangtze River. It is bordered by Kansu and Shensi provinces on the north, Hupeh and Hunan provinces on the east, Kweichow and Yünnan provinces on the south, and Sikang Province on the west. Its area is 117,080 sq. mi. Chengtu is the provincial capital.

Szechwan was probably more Indian than Chinese in ancient times, but by the period of the Three Kingdoms (A.D. 220-589) it was thoroughly Chinese and was included in the Kingdom of Shu, by which name it is still sometimes called. It was divided into four *taos,* Chienan, Eastern Shanan, Western Shanan, and Chienchung, during the T'ang Dynasty (618-907), and into four routes, Yi, Tse, Lee, and Kwei, during the Sung Dynasty (960-1279.) It was made a province during the Mongol Dynasty (1279-1368). When the capital of China was moved to Chungking in Szechwan during World War II, the province became the economic and political center of China. Most of the inhabitants are Chinese of the Han race, although some Lolos and Miaos are found. The dialect is Upper Yangtze Mandarin, which is understood along most of the Yangtze River.

Szechwan extends more than 400 mi. east and west at its widest point and more than 300 mi. north and south. It is a red-sand basin, completely encircled by mountains that isolate the province to a great extent. The mountains to the west are a continuation of the Tibetan Plateau and include the 9,957 ft. Mount Omei, sacred to Buddhists. To the south and southwest are the Talow and Taliang *shan,* while to the north is the Mien Shan. The Ta Pa Shan extends along the northeastern and eastern borders of the province.

The Yangtze River enters the southwestern corner of the province and is fed by four tributaries before it leaves through the Yangtze Gorges to the east. The four tributaries, the Min, To, Pei, and Kialing, are the source of the province's name, Szechwan, which means "four streams." The Yangtze is the principal means of communication with the rest of China; there are no railroads, and the highways that were built during the war with Japan provide few outlets from the province. The Yangtze Gorges, formed by the river forcing its way through the Ta Pa Shan, begin near the city of Wan in Szechwan and continue toward the east for more than 200 mi. to Ichang in Hupeh. Junks and river steamers ply the turbulent waters of the gorges.

The Chengtu Plain, in the area of the provincial capital, is a subregion within the Red Basin, as the Szechwan basin is called. This compact plain, no more than 70 mi. from north to south and 50 mi. from east to west, comprises less than one thirtieth of the total area of Szechwan but nevertheless contains more than 10 per cent of the total population of the province. A rich growing area, it benefits from an irrigation system devised three centuries before Christ; the system involves dividing and redividing the waters of the Min River until the entire plain is irrigated.

Szechwan's climate is mild and moist. Along the Yangtze valley the summer temperature seldom goes as high as 100° F. while the winter temperature usually averages between 45° F. to 50° F. Snow and frost are rarely in evidence, except in the mountains, but heavy fog prevails from November until April, making the winters extremely humid and unpleasant. Annual precipitation in the province ranges from 35 in. in the north to 45 in. in the south.

Farmlands are found throughout Szechwan, and intense cultivation is practiced. Rice is the principal summer crop, wheat the principal winter crop. Other important agricultural products include sugar cane, tobacco, corn, and beans. Green tea is grown in the Chengtu Plain while silk is produced in Loshan, Santai, Langchung, and Hochuan. Over 10 per cent of the world's supply of hog bristles and large quantities of salt are produced in Szechwan. The salt brine is drawn from deep wells, some of which were drilled centuries ago by primitive methods. Insect wax, used chiefly to coat lacquerware, is a product gathered after a painstaking process of breeding and nurturing the wax-producing insects.

Szechwan, largest in area of the original provinces of China Proper, is the most populous province in all of China, despite its relatively inaccessible position. Its leading cities, in addition to Chengtu, the capital, are Chungking, wartime capital of China and counting more than a million inhabitants, Tzeliutsing, and Wan. Pop. 1947, 47,107,720. A. C. T.

**SZEGED** or **SZEGEDIN** [sɛ′gɛd, sɛ′gedin], second city of Hungary, situated at the confluence of the Tisza and Maros rivers in the southern part of the republic. Like other cities of the Great Alföld, Szeged is really a group of rural villages or peasant cities with a modern section built about the industrial center. Expansion was favored by the coming of the railroads and industries, the growth being reflected by a population increase from 32,000 in 1930 to 135,000 in 1930. The mills of Szeged, because of the great agricultural hinterland, are mostly concerned with agricultural processing, such as flour milling, distilling, beet-sugar refining, jam manufacturing, and paprika processing. Leather processing, ropemaking, and a few metalworking establishments complete the industrial make-up of this great market town. Szeged is the home port of Tisza fishermen and the greatest paprika market in the world. Pop. (off. est. 1948), 140,000. H. J. R.

**SZELL, GEORGE** [sɛl] (1897- ), Hungarian pianist and conductor, was born in Budapest on June 7, 1897. As a precocious youth, he excelled both as a pianist and composer, and before coming to the United States in 1940 he also conducted in Strasbourg, Prague, Düsseldorf, Berlin (1924-1930), and Glasgow (1937-1938) and toured Australia. Prior to his appointment as permanent conductor of the Cleveland orchestra in 1946, Szell appeared as guest conductor with many orchestras throughout the United States and also as pianist with chamber-music groups. E. L. F.

# T

**T**, *t*, the twentieth letter of the alphabet, was the last in ancient alphabets. The Egyptian hieroglyphic, which may have meant "mark," bore no resemblance to the early Semitic *taw* which did mean "mark" and is in its form suggestive of the modern sign used by illiterates in signing their name with x. Beginning with the early Semitic, the letter *T* has maintained its characteristic form, a slight modification of the right-angle cross, in all of the major alphabets. The Hebrew *taw* is less like its relatives but a faint family resemblance may be noted. The Greek *T* (*tau*) and the modern *T* are identical. In the Latin, cursive 𝒯 becomes in the Caroline style 𝒯, derived from the uncial 𝒯. The following table shows the few variations of the letter *T* from the earliest times. O. W. H-Q.

**Pronunciation.** *T* is in English, in most cases, a voiceless alveolar stop, which shares its mode of articulation with the stops *k* and *p*, and its place of articulation with *d*, *n*, and *l*. In initial position, especially before an accented vowel, English *t* is slightly aspirated, like Armenian *tʿ* or ancient Greek *θ*. This aspiration does not occur after *s*, so that the *t* of *top* is different from the *t* of *stop*. In English, however, this difference is purely phonetic, not phonemic, and the average speaker is unaware of its existence. In the United States, *t* between vowels, as in *pity, better,* and *at eight,* is very short and voiced and approaches *d*; in fact, the distinction between *latter* and *ladder* is one of quantity (duration) rather than quality. *T* is sometimes silent, as in *Matthew, mortgage, hautboy, chasten, listen, castle,* and *often,* but in *often* the "spelling pronunciation" is becoming more and more frequent, especially in emphatic speech. Combinations containing *t-* are usually pronounced as *č* (*ch*) in words of the type *question, actual, nature, righteous; ti* is pronounced as *š* (*sh*) in *patience, martial, nation,* and many other words of this kind. The pronunciation of *tt* is very much the same as that of *t*, but in words like *battle, throttle, shuttle,* and *little,* the sound is rather weak, being little more than a flip of the tongue.

The graphic combination *th* represents in English two entirely different sounds, neither of which had a symbol in the Latin alphabet. One of these is a voiceless, interdental fricative *θ*, usually found in initial or final position (as in *thin, thick, thorn; mouth, length, youth, cloth*); the other is a voiced, interdental fricative *ð*, found in initial position in many pronominal words (e.g., *that, this, then, them, the*) and between vowels (as in *gather, whether, bathing, clothing,* etc.). The occurrence of the voiced sound between vowels has produced a semantic differentiation in the pronunciation of the verb and of the noun in the following group of words: *cloth: to clothe; bath: to bathe; mouth: to mouth; loath: to loathe,* etc. The sign *th* is also pronounced as *t* in a few words, most of them foreign; among them are *thyme* (by Latin tradition), *phthisic, Thomas, Esther, Theresa,* and usually *Anthony* (where *h* is a purely graphic addition, not found in Latin *Antonius*). Conversely, in *authority, Martha, Catherine,* and in thousands of Greek words like *theater, orthography,* etc., *th* has assumed the pronunciation of *θ* by "spelling pronunciation"; in Latin, whence these words came into English, *th* was pronounced *t*. For voiceless *θ*, as in *thorn,* Middle English had a special sign *þ*, which was called "thorn," but this has now gone out of use.

Etymologically, in accordance with the formulations of Grimm's Law, an English *t* of Old English origin corresponds to a *d* in Latin, Greek, Slavic, Sanskrit, and other Indo-European languages (Eng. *ten, two;* Lat. *decem, duo;* Gr. δέκα, δύο; Russ. *djesjat, dva;* etc.). An English *d*, according to the same law, corresponds to a Latin *f*, Greek *θ*, and Sanskrit *dh*, all representing very probably an ancient Indo-European aspirated sound (Eng. *door,* Lat. *fores,* Ital. *fuori,*

| *Origin* | *Form* |

| *English* | T |

Gr. θύρα). English *th*, in turn, corresponds to *t* in Latin, Greek, and other languages (Eng. *thin,* Lat. *tenuis,* Gr. ταν-ύς, etc.). In High German, in accordance with the consonant shift formulated in Grimm's Law, *t* became *ts* (Eng. *ten:* Ger. *zehn*); *d* became *t* (Eng. *door:* Ger. *Tür*); and *th* became *d* (Eng. *thin:* Ger. *dünn*).

Assibilation of *t* often occurs before an *i*, and even more before a *y*, *t* becoming either the affricate *ts* or (in a further stage) the sibilant *s*. Thus Latin *patientia, gratias* became *patsientsia, gratsias* in the third century of the Christian Era. This pronunciation was preserved in Italian (*pazienza,*

*grazia*); in Spanish *ts* became *θ* (*paciencia, gracia*); and in French *ts* became *s* (*patience, grâce;* whence English *patience, grace*).

Between vowels, *t* is apt, like all voiceless stops, to become voiced (as in English *pity*), to weaken progressively to a voiced fricative (*δ*), and even to disappear. This development is common to all the western Romance languages, including Portuguese, Spanish, Catalan, Provençal, French, Rhaeto-Romance, and Northern Italian. French has gone further than the others, for Latin *t* has entirely disappeared in words of direct tradition (Lat. *amata* > Fr. *aimée,* Lat. *pratum* > Fr. *pré*). Spanish is in the fricative stage (*chiflado, salado, prado,* with *d* pronounced *δ*), but pronunciations like *salao* are frequent among the lower classes. Provençal, Catalan, and Northern Italian are in the *d*-stage, their *t* being a voiced stop.

Some languages (Sicilian, Calabrese, Sanskrit) have also an "inverted," "retroflex," or "cacuminal" *t,* usually written *ṭ* by scholars, which is articulated farther back than the English *t*. The alveolar *t* is so characteristic of the English language that it marks the nationality of an English or American speaker whenever he pronounces it in a non-Germanic European language such as French.

*T* is the second most frequent letter of the English alphabet, averaging 95.9 per 1,000, immediately after *e,* which averages 123.1. It is far the most frequent consonant, the next being *n,* with 71.9. The letter *t* is used, however, alone and in the digraph *th,* to represent four different sounds: voiceless and voiced *t,* and voiceless and voiced *th*. G. B.

**TABARD INN,** the hostelry in Southwark, just across London bridge, where the pilgrims of Geoffrey Chaucer's *Canterbury Tales* spent the night before beginning their journey to Canterbury. The sign over the entrance was a short sleeveless coat with armorial bearings, then called a tabard. The host's name was Harry Bailey. In Chaucer's time there was in Southwark an actual inn with this name. R. K. R.

**TABER,** a town in Alberta, Canada, 32 mi. east of Lethbridge. It is the trade center for a rich irrigated agricultural and ranching area. Some oil is produced in the vicinity. The town is served by the Canadian Pacific Railway. Pop. 1951, 3,042. D. G. G. K.

**TABERNACLES, FEAST OF.** *See* SUKKOTH.

**TABLATURES** [tæ′blətshərz], old types of musical notation intended for use with certain specific instruments or families of instruments. They are all somewhat different from the normal notation used for most kinds of music. Tablatures are particularly characteristic of the fifteenth, sixteenth, and seventeenth centuries, although there are isolated examples in the fourteenth century. The most important kinds of tablatures were those for the organ, the clavichord, the harpsichord, and other keyboard instruments, and for instruments of the lute family. Of the keyboard tablatures, the German examples from the fifteenth and early sixteenth centuries are most characteristic. In these the highest part in the composition, corresponding to the soprano, is indicated in ordinary notation; the lower parts are indicated by letters written below the staff.

Lute tablatures began to appear in the early sixteenth century. German lute tablature, which had a short life, had a complicated system of letters and other symbols to refer to particular strings and frets on the instrument. The French, Italian, and Spanish systems were more practical. The lines, usually six in number, used in these tablatures do not constitute a staff but rather refer to the various strings of the lute, arranged in order from top to bottom. Letters or numbers placed upon a particular line refer to particular frets upon the corresponding string, or pair of strings, since most of the strings were doubled to increase sonority. Such a tablature thus provided the player with a clear picture of how he was to play the piece, but, on the other hand, the musical structure of the composition was not immediately apparent and could only be realized by translating the tablature into normal notation, as is done in modern editions of this music. Tablatures for ukulele and guitar came into use in the popular sheet music of the twentieth century. C. W. F.

**TABLE TENNIS,** an indoor adaptation of the game of lawn tennis, played on a table-sized court, with a small, very light, hollow celluloid ball and small wooden rackets or paddles. The exact origin of table tennis is not known, but the game became popular in England and the United States during the last part of the nineteenth century. Commercial interests in England and America popularized it under the trade name "Ping-pong," and during the first years of the twentieth century the game became sensationally popular, particularly in England. At that time, when a web-covered ball was used, the game was also called "whiff-whaff" and "gossima." The racket originally was a somewhat clumsy, paddle-shaped frame with a drumhead skin stretched tightly across it. When this racket was superseded about 1902 by the wooden paddle with stippled rubber face, and the celluloid ball was introduced, table tennis was greatly improved.

For a time table tennis waned in popularity, but after World War I there was a revival of interest in the game, and in 1926 the International Table Tennis Federation was organized. In the same year international team competition was inaugurated when Lady Swaythling of England donated the Swaythling Cup, which, like the Davis Cup in lawn tennis, has become emblematic of world team supremacy. The United States Table Tennis Association (U.S.T.T.A.) was organized in 1933 and is the governing body which establishes rules, sanctions tournaments, holds national championships, and fosters international play. Championships are held in men's and women's singles, men's and women's doubles and mixed doubles, boys' singles, and junior men's (ages 15 to 16) singles. Probably the best-known player to win the world championship singles title in table tennis was Fred Perry of England, who later won greater renown as a lawn-tennis player. Perry is said to attribute some of his skill in judging the spin of a ball in lawn tennis to his early training with the more highly reactive celluloid ball used in table tennis.

**Rules of the Game.** The game of table tennis is played on a firm, nonreflecting table, the surface of which is 2 ft. 6 in. off the floor. The table is 5 ft. wide by 9 ft. long and is divided into two equal courts for singles play by a net 6 ft. in length and 6 in. in height. The table must have a certain uniform resiliency as measured by the bounce (8 to 9 in.) of the regulation ball when dropped from a height of 12 in. There are no restrictions on the type or size of the racket. The ball, to be official, must meet certain size, weight, and quality specifications, in which case it bears the U.S.T.T.A. seal of approval.

Service in table tennis singles play is delivered by the same player until 5 successive points have been played, and no point is concluded until either the server or his opponent has scored a point. The ball must strike on the server's side

of the court before striking the top of the table on the opponent's court. Striking the ball before it bounces is not allowed. Unless the game goes to deuce (20 points each), the player first scoring 21 points is the winner of the game. If the game goes to deuce, the service thereafter changes with every point, and the winner is the player who first wins two points more than his opponent.

In doubles, the server serves for 5 successive points from his right-hand court into the right-hand court of the receiver, the table being divided by a line down the middle, parallel to the sides. Following receipt of service the partners alternate in playing until the point is decided. L. T. R.

**TABOO.** *See* PRIMITIVE RELIGION; TABOO, LINGUISTIC.

**TABOO, LINGUISTIC** [tăbu′], from Polynesian *tapu,* "sound," an interdiction of a religious kind, laid upon certain words and expressions. Akin to other forms of taboo which have flourished in primitive societies and are by no means extinct in advanced civilizations, linguistic taboo is a familiar phenomenon in both primitive and highly developed languages. The name *taboo* is also applied broadly in linguistics to interdictions of any kind, whether religious or not.

The mainspring of taboo is fear, especially the fear with which primitive, animistic man regarded the living universe that seemed to surround him. Not only were invisible gods present to his imagination, but he also saw in animals and in countless natural objects the habitations or even the actual shapes of spirits of all kinds. Identifying the name with the thing named, as in primitive magic, he sought to avoid the attention of these unpredictable and frequently dangerous beings by not naming them, or by naming them in a devious way.

A characteristic manifestation of taboo, which can be observed in innumerable languages, is the treatment of the name "God." As the result of religious interdiction, such as that embodied in the Third Commandment, "Thou shalt not take the name of the Lord thy God in vain," this name in many languages is either replaced by another or transformed. Thus, Hebrew *Jahve* is read *Adonai.* Greek had ὁ Κύριος as a substitute for ὁ θεός, and Latin had *Dominus* for *Deus,* a substitution that became universal in Romanian. In English *the Lord* is frequently substituted for *God; the Saviour, the Redeemer,* or *Christ,* for *Jesus; the Virgin* for *Mary.* In Italian, *il Signore, Domineddio,* and *la Madonna* are similarly used. Sometimes, as in *le bon Dieu* or *merciful God!,* the name is transformed simply by the addition of a new element.

The names of harmful deities are more frequently taboo than the name of God. For example, mention of the devil, which in medieval legend evoked the devil himself, is still avoided by many. The Greek Furies, whose proper name was Ἐρινύες (Erinyes), were frequently called Εὐμενίδες (Eumenides, "the benevolent ones") by way of appeasement. Another typical taboo name is Latin *Di manes,* "the good gods," which was applied to the baleful spirits of the dead, who were believed to return to earth as ghosts, vampires, and other terrifying shapes. The *flamen Dialis,* the chief priest of ancient Rome, was not allowed to pronounce the names of objects in several categories, corpses being one of them, and in many primitive tribes it is forbidden to mention the names of the dead.

Taboo applies, in primitive society, also to the names of certain wild animals which are harmful or dangerous to man. Thus, the name of the bear, preserved in Greek (ἄρκτος), Latin (*ursus*), and Vedic (*ṛkṣas*), has been interdicted in Germanic and Slavic, Germanic substituting a word that meant "the brown one" (Eng. *bear,* Ger. *Bär,* etc.), and Slavic substituting "the honey-eater" (*medvedi*). The transparency of these periphrases shows that the substitution was recent, for the more recent a word formation is, the clearer it is. The wolf was called *hircus,* "billy-goat," by the Sabines in ancient times; the jaguar and the boa constrictor are in one primitive area designated by substitute names at night, when they are considered most dangerous; and the eagle is called *Adler* by the Germans, probably because taboo has dictated the substitution of *edler Aar,* "noble eagle," for the simple name *Aar.* Interdictions of the names of animals are very rare, however, in modern society.

A somewhat more unexpected taboo seems to have applied in primitive society to the names of the hand, the finger, and the hair of the human body. In general, the names of other parts of the body are among the most constant elements in language, as may be seen in the following Indo-European words: Eng. *knee,* Lat. *genu,* Gr. γόνυ; Eng. *nose,* Lat. *nasus,* Russ. *nos;* Eng. *tooth,* Lat. *dens,* Gr. ὀδούς. The Indo-European names for "hand," "finger," and "hair," however, cannot be satisfactorily reconstructed, and if this void could not be explained by the operation of taboo, one would be tempted to conclude that the Indo-Europeans were handless, fingerless, and hairless. Presumably the hand and fingers of an adversary were recognized as potentially dangerous, and the many religious customs that involve cutting of the hair suggest that the hair also has been regarded as possessing some power to harm. This taboo, however, ceased to operate thousands of years ago, for in more recent times it can be seen that the names involved have been rather constant. Thus, among the Romance languages, there has been no substitution in French *doigt, main, cheveux,* Italian dito, mano, *capelli,* or Spanish *dedo, mano, cabellos;* and the same is true of the Germanic languages, English having *finger, hand, hair,* which correspond to German *Finger, Hand, Haar.*

A very common form of taboo in all modern languages is the deformation of religious names when these are used as exclamations or curses. French has *sapristi* for *sang Cristi, parbleu* or *pardi* for *par Dieu,* and *morbleu* for *mort de Dieu;* Italian has *cribbio* for *Cristo* and *la Madosca* for *la Madonna;* and English has an enormous and formidable variety, including *gosh, golly, heck, holy smoke, 's wounds, Judas priest, jiminy cricket,* etc. A simple substitution, such as *the Redeemer* for *Christ,* would be inappropriate here, for it would in no way diminish the offense to the deity, and therefore, in these cases, the taboo finds expression only in deformation.

The word *taboo* is also frequently applied, rather loosely, to certain other linguistic interdictions that are closely related psychologically to taboo proper but might better be called superstitions. These, like taboo, are caused by fear, perhaps even by fear of a supernatural power, but they are not exactly religious or animistic in nature. One such superstition forbids mention of names of ill omen. For example, the ancient Persians called the Black Sea aχšaēna-, "blue," but ἄξεινος, the Greek rendering of this name, meant "inhospitable," an ominous epithet indeed for an unknown northern sea; accordingly the Greeks substituted the name Πόντος Εὔξεινος, with the opposite meaning of "hospitable sea," and this the Romans adopted as a normal name (*Pontus Euxinus*). Similarly, the Italian city of Benevento had, before the Roman conquest, the Illyrian name *Maleuentum.* In Illyrian, *mal-* meant "hill," but in Latin it meant "bad," and to avoid suggesting that "bad fortune" attended the place, the Romans substituted *ben-,* the opposite of *mal-.* The linguistic process in both of these instances is known as euphemism. It is

similar, but not identical, to the one by which the Furies became known as *the Eumenides.*

A similar interdiction, also due to superstition, has eliminated the words meaning "to kill" and "to die" in many languages, replacing them with other words or with periphrases. For *to die,* for example, English has *to depart, to pass away, to go west, to kick the bucket,* etc., and Italian has *tirare la calzetta, dare gli ultimi,* and many more. Whereas, in the Romance languages, the Latin word for "to live" is preserved intact everywhere (e.g., Fr. *vivre,* Ital. *vivere,* Sp. *vivir*), the words for *to kill* (Lat. *interficio, occido*) have changed in almost every region (e.g., Fr. *tuer;* Ital. *ammazzare, accoppare;* Sp. *matar, dar el paseo*). The same contrast may be observed in the Germanic languages also, English *to live* being German *leben,* and English *to kill* being represented in German by the totally unrelated *töten.* It is significant in this connection that it has been impossible to reconstruct the Indo-European name of any disease, or even the name of "disease" itself.

In addition to interdictions that have their roots in religion or superstition, there are many others, of a social character, which are only distantly related to taboo. Among the innumerable classes of words affected by such interdictions may be mentioned certain European names for relatives "in law" (eg., Fr. *beau-fils, belle mère,* Sp. *padre político*) and, in many languages, the names of certain physiological functions and all that is associated with them (e.g., Eng. *rest room, smoking room;* Ger. *der Abort,* "the place apart"; Ital. *il luogo,* "the place").

From the formal point of view, a particular taboo can operate in any one or more than one of the following ways:

1. By deformation, as *heck* for *hell.*
2. By replacement, as "the honey-eater" for "the bear."
3. By the addition of a new element to the old, as *le bon Dieu* for *Dieu.*
4. By the use of an adjective drawn from the name instead of the name itself, as Greek ἥλιος, "the solar (one)," instead of **swēl,* "the sun."
5. By resort to a foreign word, as English *inferno* (an Italian word) as a substitute for *hell.* G. B.

**TABRIZ** [təbri′z], the capital and chief city of Azerbaijan, the northwestern province of Iran, situated about 60 mi. south of the Soviet border and about 110 mi. east of Turkey. The city is 4,600 ft. above sea level on a plain north of Sahand Mountain (12,105 ft.), and is flanked on the north by a brick-red range of hills on the Aji Chai or Bitter River. Located in an earthquake area, the city was almost completely destroyed by severe shocks in A.D. 858, 1041, and 1721, and has suffered from time to time from minor quakes.

Tabriz became important in early times because of its position on the great trade routes to the Black Sea and the Russian Caucasus region. An important road leads from Iraq through the Ruwandiz Gorge in the mountains along the western boundary of Iran. At the close of the thirteenth century, Tabriz was made a capital by Ghazan Khan, the Mongol ruler of an empire extending from central Asia to Egypt. His tomb, in a western suburb, is today only a mound of crushed brick and broken tile. In the early fourteenth century, the city became a great educational center, when Rashīd al-Dīn, a prime minister, who was also a noted physician and historian, founded in the suburb of Rashidiyeh an astronomical observatory, a hospital, numerous schools, and an extensive group of religious buildings, which attracted scholars and educators from many parts of the world. This center was destroyed when its founder fell from power in 1318. His rival, Taj-id-Dīn Ali Shah, built a great mosque (1312-1322), one of the most massive brick structures in the world, whose ruins became the ark or citadel of the city. Tamerlane captured Tabriz and, at the beginning of the fifteenth century, made it the capital of a vast province of his empire. Shah Jahan of the so-called Black Sheep Dynasty established his capital at Tabriz in 1436 and built the famous Blue Mosque, long known as the Turquoise of Islam, of which some tile faïence remains. In the sixteenth century, Tabriz became the capital of Shah Ismail, founder of the Safawid Dynasty, who later moved the seat of his government southeast to the less exposed city of Kazvin. Tabriz was taken by the Turks and Russians on numerous occasions but has continued to be the most important city of western Iran. Early in the twentieth century the people of Tabriz played a prominent part in the movement for constitutional government in Iran. At the time of World War I, the Russians built a railroad from Dzhulfa to Tabriz; a branch line leads to Sharifkhaneh, on the northern shore of Lake Urmia, where boats make connections with other points on the lake. For a time after World War II, Tabriz was the capital of the abortive movement for an independent state of Azerbaijan.

Tabriz is a center of rug weaving and has recently developed plants for the manufacture of leather, cotton thread, matches, and other products. A concrete grain elevator of large proportions has been built by the government. At one time there were 28 mi. of covered streets to house the bazaars, with their shops and numerous hand industries. An American mission hospital and church are located in Tabriz, but the schools formerly maintained by the American Presbyterian mission have been taken over by the government, and a university has been established. The city suffered recently from the opening of other trade routes; industry has not developed rapidly enough to maintain a rise in population; and many people have emigrated. Tabriz has an airfield and a large barracks. Pop. 1944, 213,542. J. C. Wi.

**TABULATING EQUIPMENT.** *See* Business Machines and Equipment.

**TACAMAHAC** [tæ′kəməhæk], Indian name for the balsam poplar, *Populus tacamahaca,* native to northern North America from New England to North Dakota and Alaska. The tree is much planted in the north for wind protection and ornament. It grows as high as 90 ft. W. D. B.

**TACANA.** *See* Indian Tribes, South American (*Other Linguistic Groups and Tribes*).

**TACAZZE** [takaze′], an important river, about 450 mi. long, draining the mountainous north of Ethiopia. From its source near the peak of Guna (13,881 ft.), it flows north and west into the Atbara River, in east Sudan, which flows into the Nile. The central section of the Tacazze has worn an imposing canyon, which separates the province of Tigre from the mountains of the Semien north of Lake Tana. The lower reaches of the Tacazze form part of the boundary between Ethiopia and Eritrea. This section of it, known as the Setit River, often becomes a shallow stream in the dry season. R. G. W.

**TACHOMETER** [təkɒ′mɪtər], from two Greek words meaning "speed" and "measure," an instrument ordinarily used to measure the speed of rotation of a shaft. It is usually calibrated in revolutions per minute (r.p.m.). If the instrument is of the rotating type, it may also be adapted to measure linear, or surface, speeds.

From the standpoint of use, tachometers may be classified as hand (portable) types and as stationary types. From the viewpoint of operating principles they may be classified as (1) mechanical, (2) electric, (3) vibrating-reed, (4) stroboscopic. In all except the last, a mechanical connection is required to the device the r.p.m. of which is to be measured. This connection will be permanent or momentary, depending on the use of the tachometer. In the mechanical and electric types, connection is made to the rotating shaft, whereas the vibrating-reed type is either rigidly mounted on the frame of the machine or held by hand against the frame. In the stroboscopic type, the connection is through a beam of light.

**Mechanical.** The mechanical type may make use of the centrifugal or flyball governor principle. Fig. 1 shows the operating features of such a tachometer. One end of the shaft *A* is connected to the shaft the speed of which is to be measured. The other end of *A* is connected to the centrifugal governor *W* through a set of change gears, in order to provide several ranges on the instrument. Rotation of the weights *W* about the axis *C* imparts longitudinal displacement to the rod *R*. This, in turn, moves the pointer *P* to a position dependent on the r.p.m. of shaft *A* and restraining action of the spring *S*. A scale under the pointer is calibrated in r.p.m.

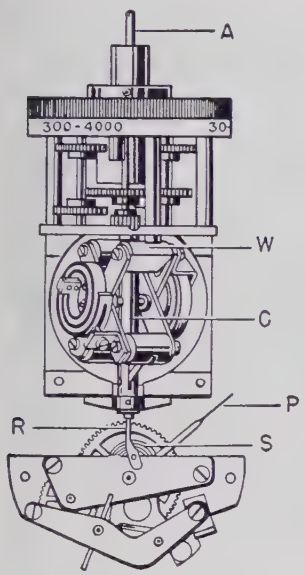

*Fig. 1—OPERATING MECHANISM OF A CENTRIFUGAL-TYPE TACHOMETER*

COURTESY OF JAMES G. BIDDLE CO.

In a hand type of mechanical tachometer, the connection between the tachometer shaft and that of the machine, the r.p.m. of which is to be measured, is usually established by pressing a cone-shaped rubber tip on the former into the centerhole of the latter. In using such an instrument, it is important to hold it parallel to the shaft of the machine the speed of which is being measured.

Another mechanical type is shown in Fig. 2. This is sometimes called the chronometric tachometer, or speed indicator. It is not an instantaneous-reading type. Fig. 3 shows the scheme of operation. The shaft *A* rotates in contact with the shaft the speed of which is desired. Upon pressing the starting button shown in Fig. 2, the wheel *B* attached to the pointer is allowed to rotate for exactly 6 sec., after which it comes to rest. The timing mechanism and its escapement, shown in the lower part of Fig. 3, are regulated to release wheel *B* at point *C* for exactly 6 sec. The dial is then calibrated in r.p.m., and in Fig. 2 the speed indicated is 1,430 r.p.m. This type, therefore, gives the average speed for 6 sec. It can also be used to measure average surface speeds in feet per minute.

**Electric.** The electric tachometer usually employs some type of electric generator, the shaft of which is connected to the shaft the speed of which is to be measured. This connection may be direct, or through gears or pulleys if necessary to provide suitable generator speeds. The generator may be either d.-c. or a.-c., but is usually of the permanent-magnet type. In the a.-c. type, the permanent-magnet structure rotates so that the voltage is produced in stationary coils. In the d.-c. type, the armature conductors are placed in slots and connected to a commutator, which usually is made of a silver alloy. The brushes are also of silver alloy, to reduce contact resistance, and are self-lubricated to provide long wear. The voltage produced at the terminal of the magneto is directly proportional to the r.p.m., and is measured by a suitable voltmeter attached to the terminals. The scale on the voltmeter is calibrated in r.p.m. The voltmeter sensitivity, in ohms per volt, must be suitable for the type of magneto used; a high-resistance voltmeter is preferred. The voltage produced is around 6 volts per 1,000 r.p.m. The most satisfactory speeds for the d.-c. magneto are from 500 to 2,000 r.p.m. If other speeds are to be measured, gear or pulley reducers may be required.

COURTESY OF HERMAN H. STICHT CO.

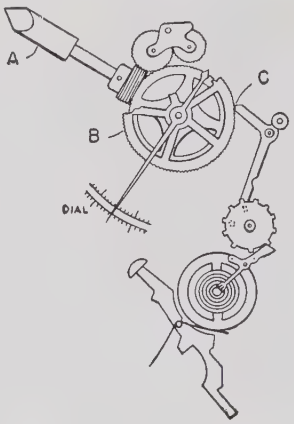

*Fig. 3—OPERATING MECHANISM OF A CHRONOMETRIC TACHOMETER*

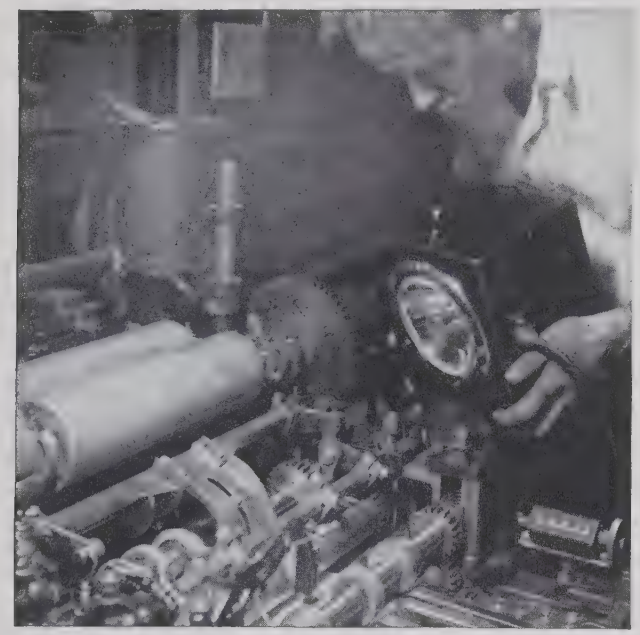
COURTESY OF JAMES G. BIDDLE CO.

*Magnetic-Drag (Aircraft) Type.* There is also a magnetic-drag type of tachometer, used in aircraft. In this type, the generator is three-phase, with rotating permanent magnets. The output is fed to a magnetic indicator having a three-phase stator winding. The rotor of the indicator consists of a permanent magnet structure and hysteresis disk mounted

on the shaft. The torque on the indicator rotor is developed by the reaction between the rotating field of the stator windings and the permanent magnets and hysteresis disk on the rotor. The speed of this rotor is synchronous with that of the generator. The indicator element has a rotating magnet assembly, coupled to the shaft of the indicator rotor. This consists of two circular plates on each of which are mounted an equal number of small permanent magnets arranged to face each other but separated by a small air gap. A thin aluminum



COURTESY OF GENERAL RADIO CO.

*Method of using a stroboscopic tachometer to measure shaft speed of rotation*

alloy drag disk is located in this air gap. The torque on this disk is proportioned to the speed of the rotating magnetic assembly, and the motion of this disk is restrained by a calibrated spring. The scale under the pointer is calibrated in r.p.m.

With the a.-c. generator and synchronous motor omitted, this drag-type indicator is used in automobiles to indicate speed in miles per hour. In this application, the rotating-magnet assembly is mechanically connected to the driveshaft by means of a flexible shaft.

*Metron.* Another type of electric tachometer is marketed under the trade name Metron. This tachometer is based on the electrical principle that the average charging current of a capacitor is proportional to the frequency at which the polarity of the voltage across its terminal is reversed. The source of voltage is a constant d.-c. voltage, which may be obtained from a flashlight battery. The tachometer head contains a reversing switch only, to provide means for varying the frequency of reversal at the capacitor in direct proportion to the speed to be measured. The circuit is so arranged that the pulsating current through the milliameter is unidirectional, and hence this meter is a sensitive d.-c. permanent-magnet type and registers the average charging current of the capacitor. The circuit constants are adjusted so that the accuracy is not dependent on the contact time or contact resistance, and the scale of the meter is calibrated in r.p.m. This type of tachometer requires less power from the rotating shaft, whose speed is being measured, than the electric tachometer previously described.

**Vibrating-Reed.** The vibrating-reed type consists of several steel reeds, each of which is tuned to vibrate at a different resonant frequency. A small rectangular indicator painted white is mounted on the end of each reed. The instrument is mounted on the frame of the machine the speed of which is desired. These instruments are available in a variety of ranges between 900 and 60,000 r.p.m., with a maximum range of about 2 to 1 in any single-scale instrument.

**Stroboscopic.** The stroboscopic tachometer employs a marked rotating disk or sector mounted on the shaft the speed of which is to be measured. This disk is illuminated by a flashing high-intensity source of light. The frequency of the flashing is controlled by electronic means and is adjustable. The duration of each single flash is of the order of a few millionths of a second. The rotating marked disk will appear stationary if the speed of the flashing light is adjusted to the speed of the disk. The dial controlling this speed of flashing may be calibrated in r.p.m. This type of tachometer is especially useful at high speed. C. C. Wh.

**TACITUS, CORNELIUS** [tæ′sɪtəs] (c. A.D. 55-c.117), Roman historian, served as praetor in 88, became consul suffectus in 97, and governed the province of Asia as proconsul in 112-113. Five works of Tacitus have descended to us: the *Dialogus de oratoribus,* a concise dialogue on the decline of oratory; the *Agricola* (*De vita et moribus Iulii Agricolae*), a brief biography of his father-in-law, Gnaeus Julius Agricola, sometime governor of Britain; the *Germania* (*De origine situ moribus ac populis Germanorum*), a short essay of prime importance as our best source of information about the ancient Germans; the *Historiae,* a narrative of the principates of Galba, Otho, Vitellius, Vespasian, Titus, and Domitian (A.D. 51-96); and the *Annales* (*Ab excessu divi augusti*), an account of the reigns of Tiberius, Caligula, Claudius, and Nero (A.D. 14-68).

Because of its style, which differs markedly from that of his other writings, the *Dialogus* was assailed for more than four centuries as unauthentic, but by the beginning of the twentieth century the tide of criticism had turned and Tacitus' claim to its authorship has since achieved common acceptance. The date of composition of this treatise is uncertain, but the difference in style had induced most investigators to infer an early date for its composition and thus to assign it to the reign of Titus (79-81). The *Agricola,* which is commonly considered the *chef d'oeuvre* of Roman biography, is not, however, limited to biographical considerations, but extends its discussion broadly to the climate, geography, and ethnology of Britain as well as to the conquest of that island by Rome. Furthermore, while it is a professed panegyric, it is also a diatribe against Domitian (81-96), whose despotism Tacitus depicts in strong terms. The *Agricola* was written in A.D. 98. In the *Germania,* written in the same year, some see a satire on Roman decadence while others consider it a political pamphlet deprecating an aggressive Roman policy against the bellicose Germans; most, however, regard it as merely an indication of interest in the Teutonic tribes, though no evidence that Tacitus visited Germany exists. *The Historiae,* an annalistic work written at some time before 112, was originally divided into fourteen books, but of these only the first four and part of the fifth, covering the years 69-70, remain to us. In the case of the *Annales,* though sixteen books were originally written, we now have only the first four, a fragment of the fifth, most of the sixth, and the eleventh to the sixteenth, of which the beginning of the eleventh and the end of the sixteenth are missing. The extant portions cover the periods 14-37 and 54-66. This annalistic history is Tacitus'

latest known work, finished about 117 and recognized as his masterpiece.

Tacitus' renown as a historian was eminent during his generation, and succeeding centuries have not dimmed the brilliance of his fame. He is both our principal and our best source for the history of the period from 14 to 96. Of all Roman historians he is indubitably the most scientific by later standards; he falls beneath his competitors in some other respects, however, for while we may accept his factual statements with confidence, we must constantly query his interpretations, in which he is prone to color his facts "to point a moral or adorn a tale." Nevertheless, all competent students concur that among Roman historians Tacitus has neither superior nor rival in portraiture of character, in psychological penetration of motive, and in graphic power to paint in a few words an act or a situation; he is unsurpassed among his rivals in his moral earnestness, his use of rhetorical devices, and his mastery of epigrammatic characterizations, of which several have passed into the common heritage of literature. Tacitus models his later style on that of his predecessor in historiography, Sallust (86-34 B.C.), belonging to the Golden Age of Latin literature; he is for all that a true son of the Silver Age of Latinity in his brevity, poetic color, Greek usages, variety of expression, and figurative style.

P. R. C.-N.

**TACLOBAN** [tɑklo′bɑn], a Philippine chartered city, the capital of Leyte Province, situated on the northeast coast of Leyte Island. Historically, it is famous as the temporary capital of the Philippines after the United States Army landed on Leyte, and served as Gen. Douglas MacArthur's headquarters early in the campaign to recapture the islands from the Japanese in World War II. Tacloban is the agricultural and distributing center of the eastern Visayan Islands and the only Leyte port with terminal facilities. The town lies at the base of a small peninsula between Samar Sea and Leyte Gulf. Rice, corn, copra, and abacá are the principal crops of the surrounding region; mat making and basket weaving are the main handicrafts. There is a national airport 5 mi. southwest of the city. Pop. 1948 (town), 31,155; (chartered city), 45,421. A. Cu.

**TACNA** [tɑ′nɑ], the name of the southernmost department of Peru and of its capital, 620 mi. southeast of Lima and 170 mi. southwest of La Paz. Near the city, which was involved in the Tacna-Arica dispute with Chile, is the Campo de la Alianza, site of an important battle (1880) in the War of the Pacific (1879-1884). Tacna was awarded to Peru on Aug. 28, 1929. The city is the agricultural center of the region and manufactures cotton and sugar. There is a railway to Arica in Chile, 40 mi. to the south, and from there to La Paz in Bolivia. The city is also on the west branch of the Pan-American Highway going south from Vitor to Chile. The department, with an area of 4,922 sq. mi., is bordered by the departments of Moquegua on the northwest and Puno on the northeast, and by Bolivia on the west, Chile on the south, and the Pacific Ocean on the southwest. Although most of the terrain is barren hills, the province has some fertile oases producing fruit and vegetables. There are also some sulphur mining and a tanning industry. Pop. (off. est. 1947), 13,254, city; 42,070, department. *See also* TACNA-ARICA DISPUTE. S. G. I.

**TACNA-ARICA DISPUTE** [tɑ′nɑ ɑri′kɑ], a boundary disagreement in South America which led to the War of the Pacific (1879-1884), between Chile on the one hand and Peru and Bolivia on the other. The dispute arose in the mid-nineteenth century over the exploitation by Chile of valuable guano and nitrate deposits in sections of the Pacific coastal region that were claimed by Bolivia. In the ensuing war, which Peru entered on the side of Bolivia, Chile was victorious and, as a result, gained outright possession of Bolivia's entire seacoast territory and the Peruvian province of Tarapacá. Under the Treaty of Ancón (1883), between Peru and Chile, Peru also ceded Tacna and Arica to Chile for a period of ten years, after which a plebiscite was to be held to determine their permanent status. The decision, however, was postponed from decade to decade. At the close of World War I the United States was invited to supervise the plebiscite, but an attempt to hold it, under the supervision of Gen. John J. Pershing, failed because of national feeling in the rival countries. The question was finally settled by direct negotiation in 1929, when a division of the territory was agreed upon. Part of Tacna was then restored to Peru, but Chile retained the rest of that province and all of Arica. *See also* ARICA; TACNA. S. G. I.

**TACOMA** [tə′ko′mə], a port city in the central section of western Washington, the county seat of Pierce Co., situated on Commencement Bay, at the head of deep-sea navigation of Puget Sound and at the mouth of the Puyallup River, about 30 mi. south of Seattle.

**Harbor.** The Tacoma harbor is considered one of the best natural harbors in the world. There are 14 mi. of shoreline along it. To reach it from the Pacific Ocean vessels pass through the Strait of Juan de Fuca, Admiralty Inlet, and Puget Sound. The harbor is 4½ mi. wide at its entrance between Brown's Point and Point Defiance. It has an average width of nearly 2 mi. and a length from Brown's Point to the head of the harbor of approximately 2½ mi. There is an average depth of 25 to 30 fathoms.

**History.** In 1833 the first fort on the north Pacific coast was constructed 18 mi. south of the city's site by the Hudson's Bay Company for protection against the Indians. The fort, known as Fort Nisqually, has been reproduced in its entirety, including one of the original buildings, at Point Defiance Park in Tacoma. Tacoma was founded in 1868 when General Morton Matthew McCarver selected the site as the terminus for the Northern Pacific Railroad. He purchased the land and induced a California lumber company to build a sawmill, thus starting Tacoma's principal industry. The townsite he plotted near the mill was called Commencement

City, but in 1869 McCarver changed the name to Tacoma, which is said to be a corruption of an Indian term meaning "greatest white peak." A post office, which is preserved as a landmark in Point Defiance Park, was built in that year. In 1873 another post office was established 1½ mi. south under the name of New Tacoma. This community became the county seat in 1880. Tacoma made its appearance in the export-shipping field in 1881 when the first load of wheat was sent out. In 1884 the two neighboring communities consolidated as one city named Tacoma. The city has the commission form of government.

**Points of Interest.** The Olympic Mountains are northwest of the city; the Cascade Range is to the east. Tacoma is considered the gateway to Mount Rainier National Park, to the southeast, and it is 60 mi. southeast of Olympic National Park. Tacoma is reputed to have the tallest totem pole in the world, 105 ft. high, which was carved from a single cedar tree and presented to the city in 1903. The state historical museum contains numerous exhibits of Washington and Alaska Indian handiwork. The city has twenty-seven parks, comprising 1,616 acres. In Point Defiance Park there are a zoo, deep-sea aquarium, and numerous recreational facilities. Sutter's Exhibits, a rock collection, has a large display of fluorescent rocks.

**Institutions.** The College of Puget Sound is located in Tacoma, and Pacific Lutheran College is 7 mi. south of the city's center. Hospitals include an Indian hospital, Madigan General Hospital (an army hospital), a veterans' hospital, the Western State Hospital for the insane, and a county hospital.

**Federal Installations.** The armed services maintain several installations in the Tacoma area, including Fort Lewis (a 110,000-acre army post), Mount Rainier Ordnance Depot, McChord Field, and the Tacoma naval station.

**Transportation.** In addition to the steamship lines, transportation is provided by the Northern Pacific, the Great Northern, the Union Pacific, and the Chicago, Milwaukee, St. Paul and Pacific railroads. Air service is available at the joint Seattle-Tacoma airfield, about 15 mi. south of Seattle, which has flights by the Northwest, Pan American, Trans-Canada, United, West Coast, and Western air lines.

**Industry.** The city is one of the nation's largest furniture, door, pulp, and plywod centers. Tacoma's leading industrial establishments include a smelter, which refines copper, gold, and silver; railroad shops; shipyards; fruit canneries; and flour mills. The city is the center of the Northwest's electrochemical industry. The factory output also includes food products, castings, cranes, logging machinery, candy, and clothing. Pop. 1950, 143,673. S. D. M.

**TACTICS, MILITARY.** *See* Military Strategy and Tactics.

**TADEMA.** *See* Alma-Tadema, Sir Lawrence.

**TADPOLE SHRIMP,** a primitive freshwater crustacean belonging to the order Notostraca of the subclass Branchiopoda. Tadpole shrimps are usually brownish in color and have a broad oval shield covering the anterior segments, which gives them an appearance similar to that of miniature (1-in.) horseshoe crabs. They are usually found in temporary pools and, like many of the branchiopods, their presence in any particular locality can seldom be relied upon from one year to the next. In some rice-growing areas they are looked upon as pests which interfere with the growth of young rice shoots. The presence of related fossil forms in Cambrian deposits indicates that these unique animals are among the oldest of living crustaceans. F. A. C.

**TADZHIK SOVIET SOCIALIST REPUBLIC (TADZHIKISTAN)** [tajɪ′k, tajɪ′kɪstɑ′n], one of the sixteen constituent republics of the Union of Soviet Socialist Republics, located in west central Asia north of Afghanistan. With an area of 55,700 sq. mi., it is bounded on the north and west by the Uzbek S.S.R., on the south by Afghanistan, on the east by Sinkiang, and on the northeast by the Kirghiz S.S.R. Acquired as part of Russian Turkistan in 1895 and formed from parts of the former regions of Bukhara and Turkistan, it was admitted as a constituent republic of the Soviet Union on Dec. 5, 1929, and includes the Gorno-Badakhshan Autonomous Territory within its borders. The republic consists almost entirely of young folded mountains with elevations reaching below 2,000 ft. only in the extreme southwest, while in the east the Pamir Mountains average well above 10,000 ft., culminating in Mt. Stâlin, 24,590 ft., the highest peak in the Soviet Union.

Owing to the high elevation, the climate of the republic is rather severe for its latitude, and varies considerably with the relief. Mean January temperatures range from 25° F. to 32° F. and July temperatures from 60° F. to 65° F., while annual precipitation varies from 10 to 15 in. In the western semi-desert along the upper reaches of the Amu Darya and the Syr Darya rivers precipitation is only about 6 in. a year. Soil, in the mountains, is thin and leached, but in the valleys, particularly in the southwest, irrigation is practiced and the region is important for the growing of cotton. The Amu Darya on the southern border is the principal river; others include the Syr Darya, the Panj (or Pyandzh), the Kafirnigan, and the Vaksh, which flow through the mountains in deep gorges. There are many permanent glaciers in the Pamirs, and in the northeast, Lake Kara Kul lies well over 2 mi. above sea level. The low rainfall prevents the growth of extensive forests except at fairly high elevations in the mountains.

The capital and leading city is Stalinabad, in the western portion of the republic. Other important cities include Khorog in the southeast, Garm in the central part, and Kurgan Tyube in the southwest. The population consists primarily of Tadzhiks, an Iranian people of Mohammedan faith and indigenous to the region. Those in the western Pamirs are the oldest of the peoples of Central Asia. The smaller portion of the population is made up of Uzbeks, Kirghizes, and Russians. Native culture is actively encouraged and over 300 schools of various levels are included in the republic's educational system. A branch of the Soviet Academy of Sciences has also been established in Tadzhikistan.

Agriculture is the historic occupation of the Tadzhiks, and the principal crop is Egyptian long-staple cotton, grown on the irrigated lands of the river valleys. Other crops include rice, apricots, and other fruits. The silkworm is cultivated, and grain and orchard crops are grown in the mountain regions. In the high semi-desert valleys of the eastern Pamirs, 13,000 ft. above sea level, the nomadic Kirghizes raise cattle, sheep, and yak.

The chief industries of Tadzhikistan are concerned with mining and the processing of agricultural products. Coal, petroleum, gold, silver, platinum, radium, lead, zinc, tin, uranium, arsenic, and bismuth are mined in the mountains. In addition, there are many large phosphate deposits and still-untapped areas rich in minerals. Kurgan Tyube boasts the largest cotton-ginning mill in central Asia; Stalinabad has a large meat-processing combine; and Leninabad has fruit-canning facilities. Other factories producing leather goods, cotton and silk fabrics, and cottonseed oil support the

republic's industrial activity. Four thousand miles of roads over difficult mountains and the wide use of air transport have supplanted trails, thus reducing the inaccessibility of Tadzhikistan. Stalinabad is also reached by a railway from Uzbek S.S.R. Pop. (est. 1954), 1,800,000.

R. H. F. and L. M. A.

**TAEGU** or **TAIKYŪ** [taigu, taikyu], the fourth largest city of Korea, in the southern part of the peninsula, 60 mi. northwest of Pusan on a tributary of the Naktong River, at 35° 47′ N. lat. and 128° 31′ E. long. Taegu has a continental climate, with cold winters and hot summers. The average annual temperature is about 53° F., and the average annual precipitation is 35 in. Silk spinning is the major economic activity of Taegu, and the city is an important market center and railroad junction. During the Korean War Taegu was for several weeks in 1950 the provisional capital of South Korea. Communist attempts to capture the city were prevented by U.N. forces. Pop. 1946, 269,113. J. E. F.

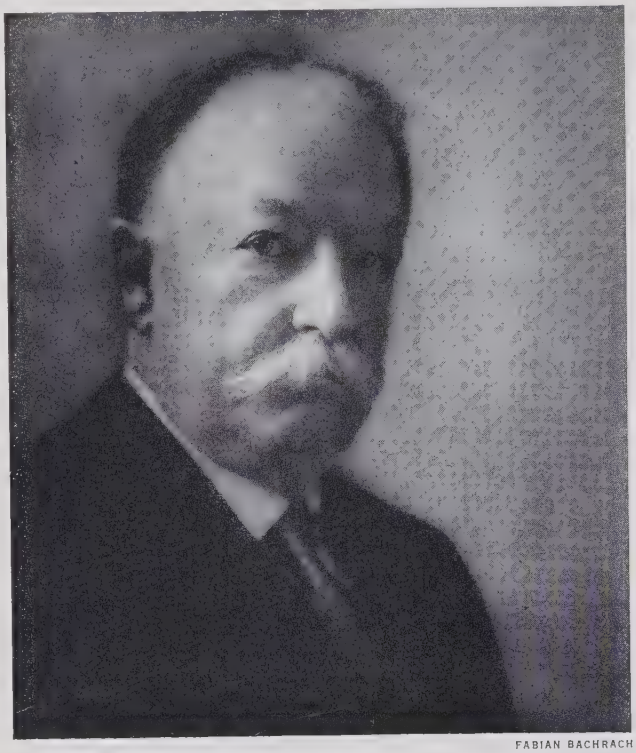
**TAFT, LORADO** (1860-1936), American sculptor, lecturer, and writer, was born April 29, 1860, in Elmwood, Ill. He studied sculpture at the University of Illinois and in Paris. After 1886, through his teaching of sculpture and the history of art at the Art Institute, Chicago, Taft broadened the scope of art education throughout the Middle West. In 1903 he wrote *The History of American Sculpture*. Taft's work is conservative, but robust and flexible; he was pre-eminent as a fountain sculptor. He died in Chicago Oct. 30, 1936.

P. E.

**TAFT, ROBERT ALPHONSO** (1889-1953), American political leader, was born in Cincinnati, O., on Sept. 8, 1889, a son of President William H. Taft. He graduated from Yale University in 1910 and from the Harvard University Law School in 1913, at the head of his class. He was admitted to the Ohio bar in 1913, and began practice at Cincinnati. Because of defective eyesight, he was rejected for military service in World War I, but was assistant counsel in the United States Food Administration (1917-1919) and counsel to the American Relief Administration in Europe (1919-1921). Taft was elected to the Ohio house of representatives in 1921, and served until 1926, being speaker in the latter year. In 1931-1932 he served a term in the Ohio senate, and in 1936 was Ohio's "favorite son" in the Republican national convention. Two years later he was elected to the U.S. Senate and was re-elected in 1944 and 1950, serving in that body until his death. During his years in the Senate, Taft was one of its most influential members and had considerable effect on legislation. He was a sponsor of the controversial Taft-Hartley labor act. Taft proved to be an effective spokesman for the conservative element of the Republican Party and gradually assumed leadership of that group. He was the candidate of that wing of the party for the Republican presidential nomination in 1940, 1948, and 1952, although failing in each instance to capture the nomination. His most successful bid came in 1952 when he was defeated at the convention by Dwight D. Eisenhower only after a bitter intra-party struggle. After Eisenhower's election to the presidency, Taft was a powerful, though at times critical, supporter of the Eisenhower administration. He died in New York after a brief illness on July 31, 1953.

T. R. H.

**TAFT, WILLIAM HOWARD** (1857-1930), twenty-sixth President of the United States, was born in Cincinnati, Ohio, Sept. 15, 1857. His father, Judge Alphonso Taft, diplomat and cabinet officer under President Ulysses S. Grant, and his mother, Louisa Torrey Taft, were of early New England families of English descent. After attending the public schools in Cincinnati, Taft was sent to Yale University, from which he graduated in 1878, second in his class. He then entered a Cincinnati law school and subsequently was admitted to the Ohio bar. His progress in the law was steady if not spectacular. From the first, however, it was apparent that Taft was not too ambitious, and his brothers chided him for his lack of diligence in preparing a case. The



FABIAN BACHRACH

*WILLIAM HOWARD TAFT, TWENTY-SIXTH PRESIDENT OF THE UNITED STATES*

facts seem to indicate that throughout his life Taft preferred to depend upon his native brilliance rather than upon hard work to see him through a problem. He was a sociable person, loving life and good company too much to spend a great amount of time in lonely, concentrated labor. This trait was to cost him dearly when he became president.

Shortly after graduating from law school, Taft, following in the footsteps of his father, became interested in Republican politics. He was an excellent public speaker, and his services to his party soon resulted in his being appointed assistant prosecuting attorney of Hamilton County. From that time on, except for several brief periods, he was to hold public office for the rest of his life. In 1882 he was appointed the collector of internal revenue for Cincinnati, a position he resigned after he had refused to discharge several able men because of their political affiliations. Soon afterwards, however, he was made assistant solicitor of Hamilton County, an office he held until 1887 when he was appointed a judge of the Ohio Superior Court. Meanwhile, in 1886, he had married Helen Herron of Cincinnati.

Taft was never happier than when he was on the bench. The calm, leisurely tempo of judicial life suited his nature

as it had his father and grandfather before him. Since he had been appointed only to fill an unexpired term, he stood for election in 1888 and won his only victory at the polls prior to his election as President. With regret he left the Ohio bench in 1890 to accept the position of Solicitor General of the United States under President Benjamin Harrison. He was extremely successful in his new position, winning the great majority of his cases. The true bent of his nature was again shown when, in 1892, against the advice of his wife, he joyfully resigned to become a Federal circuit judge. On this second most important court in the nation, Taft soon acquired the reputation of being a reactionary, and especially of being an antilabor judge. This label, fastened to him largely as a result of his findings in a few celebrated injunction and contempt-of-court cases, was not quite just. For although Taft was and remained a conservative all his life, he did believe in the right of labor to organize and strike, and so expressed himself from the bench. As a judge he was especially solicitous of labor suits for compensation resulting from industrial accidents. However, his willingness to issue labor injunctions earned for him the opposition of organized labor for the rest of his life. One of his most important decisions, the Addyston Pipe and Steel Co. case, affirmed by the Supreme Court, enjoined conspiracy in restraint of trade and put the first teeth into the Sherman Anti-Trust Act.

In 1896 Taft was chosen dean of the University of Cincinnati Law School; later he was urged to become a candidate for the presidency of Yale University. In 1900 President William McKinley appointed him president of a commission to establish civil government in the Philippine Islands. A year later he was made the civil governor of the islands. His work in restoring normal civil life throughout the Philippines brought him to the attention of President Theodore Roosevelt, who twice offered to appoint him to the United States Supreme Court. Regretfully declining in each instance, Taft remained in the Philippines until he considered his job there finished, leaving only to accept an appointment as Secretary of War in 1904. Roosevelt and Taft made a happy combination. Taft's unimpeachable integrity, his complete faithfulness, and his easygoing nature made him a perfect foil for the restless and impetuous President. He soon became Roosevelt's most trusted adviser, one of his most successful administrators, and his ablest trouble-shooter. Whenever a situation became too difficult for lesser men to handle, it was Taft who was sent to "sit on the lid," as Roosevelt phrased it.

Meanwhile, Roosevelt's second term was approaching an end. Many of Taft's friends were already booming him as the successor. For a long time Taft refused to become an active candidate, but when Roosevelt himself chose him he accepted, and was elected over William Jennings Bryan in 1908 by an electoral vote of 321 to 162. The legislative record of the Taft administration was an impressive one. In the four years, additional power was given to the Inter-State Commerce Commission, a postal savings and a parcel post system were created, and civil service was extended. A new cabinet post, that of Secretary of Labor, was added, and the sixteenth and seventeenth amendments were passed providing for a national graduated income tax and for the direct election of senators, respectively. Moreover, Taft energetically continued Roosevelt's "trust-busting" policies and his conservation program. In ordinary times and with ordinary luck this record should have commended the President to the country, but the times were not ordinary. For one thing, the nation, spurred on by Roosevelt's preachings, was excessively reform-minded, and the President appeared, by comparison at least, to be timid in his adoption of new ideas. For another, the President had the misfortune to follow the extremely colorful and adroit Roosevelt, and, although Taft was one of the most likable of men, he was neither colorful nor politically acute. Taft was too easygoing, with a disposition to trust his subordinates too much, too dilatory in his preparations, and probably too conservative to suit the existing temper of the country. Soon after his election he called Congress into special session to enact a campaign promise to reduce the tariff. The Payne-Aldrich Act of 1909 was not a reduction in any real sense, and Taft's approval of the bill and subsequent ardent defense of it served to alienate progressive sentiment in the nation. He further sacrificed liberal support by his dismissal of Gifford Pinchot from the forestry service, a militant supporter of conservation and a personal friend of Theodore Roosevelt. In the ensuing famous Ballinger-Pinchot episode, a congressional investigation cleared Richard A. Ballinger, Secretary of the Interior, of any wrongdoing, but left the public critical of the administration's conservation policies. Taft suffered a further defeat in his proposal for tariff reciprocity with Canada. He called a special session of Congress, against the advice of his party leaders, and then widened the split in his party to obtain passage of the act, only to see the project rejected by a Canadian election.

As progressive sentiment grew more critical of him, Taft relied more upon the conservative elements of his party. In the primaries of 1910 the President worked actively for the defeat of liberal Republicans. Soon after the Democratic victories of that year a movement was started to by-pass Taft in 1912 and nominate a progressive Republican. Senator Robert M. LaFollette was the early choice of the progressives, but by 1912 they were supporting Theodore Roosevelt. Since his return to the country in 1910 Roosevelt had become increasingly critical of the President, and when in 1911 Taft authorized an anti-trust suit against the United States Steel Corporation, for actions that had had Roosevelt's approval when President, the two men were completely estranged. In an acrimonious campaign of personalities the two old friends waged a bitter battle. Roosevelt was probably the choice of the majority of the Republicans, but Taft controlled the national party organization and prevented the seating of Roosevelt delegates, thus insuring his own nomination. Enraged, Roosevelt bolted and formed the Progressive Party. In the three-cornered contest that followed between Taft, Wilson, and Roosevelt, Taft received the electoral votes of Vermont and Utah alone.

Retiring from the presidency on March 4, 1913, Taft became the Kent Professor of Constitutional Law at Yale University. During the same year he was elected president of the American Bar Association. Taft thoroughly enjoyed the quiet academic atmosphere, but World War I brought him back into public life. He made a notable record as joint chairman of the War Labor Board, and in 1918 and 1919 he spent a great amount of time lecturing in support of the League of Nations. Taft had always been a firm supporter of world peace, and an international organization capable of administering and enforcing international law greatly appealed to him. Nevertheless, in the elections of 1920 he supported Warren G. Harding on the ground that the election of a Republican administration was the best way of insuring that the nation join the League. His opposition to Wilson brought him again into close contact with Theodore Roosevelt, and before Roosevelt's death they had renewed their friendship.

Perhaps the happiest moment in Taft's life came in 1921 when President Harding appointed him Chief Justice of the United States Supreme Court. Of all occupations, the bench had always held the greatest attraction for him. As Chief Justice, Taft was responsible for many administrative improvements in the Federal judicial system. At his suggestion regular conferences of the senior circuit court justices were held, and thus a degree of regularity was imparted to the hitherto unco-ordinated system. It was at his suggestion that Congress passed an act giving the Supreme Court the power to decline to hear certain classes of cases. When Taft first came to the Court it was considerably behind in its work; at his resignation its schedule of cases was almost current. Taft was also largely responsible for obtaining congressional approval for the construction of the new Supreme Court Building. During the time Taft was Chief Justice the Court, in its decisions, tended toward the conservative. Taft himself was a conservative force, although on several notable cases he wrote liberal opinions. His dissenting opinion on the District of Columbia minimum wage law for women was particularly expressive of the progressive viewpoint. On Feb. 3, 1930, the Chief Justice resigned from the Court because of ill health. A month later, on March 8, he died; he was buried in the Arlington National Cemetery.

Taft was extremely large and jovial, and moderate in everything save eating. Unfortunately, he became president in an age of reform to which he could not give full assent. This, plus his peculiar lack of political sense, made his presidential years not entirely happy. However, his achievements as judge and administrator were considerable.

G. E. M.

**TAFT-HARTLEY ACT.** *See* INDUSTRIAL PRODUCTION; LABOR IN THE UNITED STATES, HISTORY OF; LABOR PRACTICES AND EMPLOYMENT (*Methods of Settling Labor Disputes*).

**TAGANROG** [təgʌ′nrɔ′k], a seaport and industrial city in the western Rostov region of the Russian Soviet Federated Socialist Republic, southwest Soviet Union, 39 mi. west of Rostov-on-Don. It is located on the flat northern coast of the Gulf of Taganrog, the northeastern extension of the Sea of Azov. The original thirteenth-century colony of Italian merchants was destroyed by the Mongols. A small community soon developed, and after a period of Turkish control it became Russian in 1769. Taganrog was an important port and trade center between the mid-eighteenth and mid-nineteenth centuries, but its port then declined when the harbor became silted up. The harbor, icebound about three months annually, is reached by channels dredged in the bed of the shallow Sea of Azov. Taganrog has greatly expanded as an industrial city under the Soviet regime. It was heavily damaged in the fighting involved in its capture in World War II by the Germans, Oct. 19, 1941, and its recapture by Soviet troops on Aug. 30, 1943. Anton Chekhov was born in Taganrog in 1860. Notable is the former Imperial Palace in which Alexander I died in 1825. A deep-water port for Rostov-on-Don, Taganrog transships from that city many of its export items, including grain, caviar, wool, butter, and oil; the imports are chiefly items for local consumption. The city's industries, largely Soviet-developed, include in their output iron and steel, steel boilers, turbines, hydraulic presses, metal tubing, machines, leather, and leather products. Pop. (est. 1950), 175,000.

C. C. H.

**TAGAYTAY** [tɑ′gitī′], a Philippine city, 33 mi. south of Manila, in Cavite Province, Luzon. Located on a ridge 2,000 ft. above sea level and overlooking Lake Taal and the inactive Taal Volcano on an island in the lake, the city is a market center for coffee, fruit, coconuts, and vegetables grown in the area. Pop. 1948, 5,233.

**TAGORE, SIR RABINDRANATH** [tɑ′gor] (1861-1941), renowned Hindu poet and educator, was born in Calcutta on May 6, 1861. He received his education from his father, whom he accompanied on numerous pilgrimages and trips throughout India. In 1877 he went to England to study law but returned to India the following year. His first poems were imitations of two older Bengalese poets, Chaulidas and Vidyapati, and in 1879 he published his first original work *Bhānu Sings* ("Evening and Morning Songs"). Tagore composed music for over 3,000 songs, including many of his later lyrics. In 1884 he married, and in 1885 he went to Shilaida, on the banks of the Ganges, to look after his father's estates. It was here that he came into contact with the genuine native life, and his later works depicted this experience. Many of his better-known works were written in this period of Tagore's life. These works include *Gītanjalī* (1912), *The Crescent Moon* (1913), *The Gardener* (1913), the drama *Chitra* (1913), and *The Hungry Stones* (1916).

In 1901 he founded the Santiniketan ("Home of Peace") school for boys at Bolpur in Bengal. The school, now an international institution known as Visva-Bharati, was Tagore's main work during the rest of his life. In 1912 Tagore visited England and, a year later, America, where he delivered many lectures which were ultimately published as *Personality* (1917) and *Nationalism* (1917). In 1913 the poet was awarded the Nobel Prize for Literature, and in 1915 he was knighted. Tagore published numerous poetic works, novels, short stories, essays, sermons, and dramas in Bengalese, some of the most important of which have been translated into English. His later publications include the drama *The King of the Dark Chamber* (1914), his autobiography *My Reminiscences* (1917), *Sacrifices and Other Plays* (1917), a second series of *Gītanjalī* (1919), *The Home and The World* (1919), *The Wreck* (1921), *Red Oleander* (1924), *Broken Ties* (1925), *Fireflies* (1928), *Thoughts From Tagore* (1929), and *The Religion of Man* (1931). Tagore died in Calcutta on Aug. 7, 1941.

F. Go.

**TAGUS** [te′gəs] (*Span.* Tajo; *Port.* Tejo), the longest river of the Iberian Peninsula, flowing in a southwesterly direction across Spain and Portugal and emptying into the Atlantic Ocean at Lisbon. Its length is about 550 mi. It rises in the Albarracin Range of the Montes Universales, on the border of Aragon and New Castile in east central Spain, about 100 mi. west of the Mediterranean Sea; it flows in a northwesterly direction into Guadalajara Province, then turns southwestward to Toledo, from which it follows a generally westward course to the Portuguese border. There, between Alcántara and Montalvão, for a distance of about 30 mi., the river forms a part of the border. In Portugal it flows southwestward between the provinces of Beira and Alentejo, crosses Estremadura, and at Santarém begins to form a broad estuary. At Lisbon, where the estuary reaches its maximum width, the river provides a fine landlocked harbor opening into the Atlantic. For most of its long course the Tagus traverses a dry, hilly terrain, where grazing is more important than agriculture. The river is navigable for about 80 mi. from Lisbon northeast to Abrantes, Portugal, but above that point the stream is broken by rapids and cataracts. The only large city on its banks in Spain is Toledo; in Portugal there are Santarém and Lisbon. The river's chief tributaries are the Jarama, Alberche, and Alagón, all in Spain.

*The Himalayan tahr,* Hemitragus jemlaicus, *a beardless wild goat*

**TAHITI** [tɑ′hiti; tɑhi′ti], largest and best known of the Society Islands, located in the South Pacific Ocean west of the Tuamoto group at 17° 45′ S. lat., 149° 30′ W. long. It is 33 mi. long and 15½ mi. wide, and has an area of about 600 sq. mi. At least seven peaks on the island rise higher than 4,000 ft. Of these Mount Orohéna, 7,339 ft., is the highest. The principal town is Papeete, on the northwestern coast, containing about 10,000 people, mainly Polynesian natives. About the same number live elsewhere on the island.. Tahiti became part of a French protectorate in 1843. In 1888 it was made the capital of the French Pacific island colonies, including the Tuamotos, Marquesas, and Austral islands, which in 1946 were constituted an overseas territory of the French Union. There are few native land animals on Tahiti, and few birds and insects, but the lagoons offshore teem with fish and shellfish. The main industries are the preparation of copra and sugar, and the export of pearl shell and phosphates. Pop. (1941) 23,133. R. G. B.

**TAHITI CHESTNUT,** a name given to the edible kidney-shaped seed of *Inocarpus edulis,* a tree of the pea family. It is highly prized as food by the natives in Polynesia and Malaya. M. G. W.

**TAHLTAN.** *See* Indian Tribes, North American (*Western and Eastern Subarctic*).

**TAHOE, LAKE** [tɑ′ho; te′ho], a lake which lies astride the boundary between California and Nevada, situated approximately 10 mi. west of Carson City, Nev. It is one of the most beautiful lakes of the western United States and the center of a thriving summer-resort area. Lake Tahoe extends 21.6 mi. from north to south and has a maximum width of 12 mi. Most of its area of 193 sq. mi. lies in California. Situated at an altitude of 6,225 ft., it is rimmed by snow-clad peaks of the Sierra Nevada towering 4,000 ft. above its surface. The lake was formed partly by glaciation and partly by faulting, erosion, and volcanic damming. It is said to be the deepest lake in the United States, the known depth being at least 1,500 ft. G. Q.

**TAHR** [tɑ′r], a short-horned goat, *Hemitragus,* which inhabits the forested mountains of India. It stands 36 to 42 in. high, and its very shaggy coat is dark brown or reddish brown. Unlike the true goats, male tahrs are not bearded. Both sexes have horns which measure up to 17½ in. The animals are gregarious and feed together in grassy openings and among the cliffs. Usually one kid at a birth is born, either in June or in July; it is much paler than its parents. V. H. C.

**TAI.** *See* Asiatic Tribes (*Sinitic*); Siamese.

**TAICHŪ** [taitshu], a city in west central Formosa (Taiwan), 118 mi. southwest of Kiirun. In 1888 Taichū was made the site of a prefectural government, controlling eight neighboring counties. During Japanese rule (1895-1945) Taichū was elevated to the status of a municipality, a position it still maintains. To the southeast of the city is the Confucious Temple, the site of a famous institute known as the Wen Kai Academy, founded in 1825 by Chinese scholars. It had a collection of 300,000 volumes of Chinese literature, the largest on Formosa. However, during Japanese rule the whole collection was either burned or removed by the Japanese as a measure to eradicate Chinese influence on the island.

Taichū is situated at the center of a fertile, irrigated basin surrounded by mountains. It has a tropical climate, with a mean temperature of 68° F. and an average annual rainfall of from 60 to 80 in. The surrounding region is chiefly agricultural, with bananas and sugar cane the chief crops and tea, rice, vegetables, tobacco, and sweet potatoes also grown. There are several large sugar mills and refineries in and near Taichū. The city, center of a local transportation network, is on a branch of the main railroad line connecting the large cities of the island. About 20 mi. east of Taichū is the scenic Sun-Moon Lake, the most attractive resort on Formosa. The hydroelectric plants on these adjoining lakes supply power to the sugar refineries, lumber mills, and other factories in near-by towns. Pop. 1947, 82,259. A. C. T.

**TAIF** [tɑ′if], a town in Hejaz, in western Saudi Arabia, about 35 mi. southeast of Mecca, situated 6,000 ft. above sea level in the mountains that form the western rim of the Arabian plateau. It serves as Hejaz's summer capital and is a popular resort for the residents of Mecca. The climate is hot and dry. Temperatures frequently exceed 100° F., and the precipitation, most of which falls in August, is usually not much more than 10 in annually. The city is noted in Arabia for its rose gardens and fruit orchards. Although the residents of Taif only became converts to Mohammedanism after Mohammed had successfully laid siege to the community in the seventh century, Taif was the only community in Arabia other than Mecca and Medina to remain faithful to the Prophet immediately after his death. In 1924 many of the residents were massacred after Taif was captured from the Turks by the invading Wahabi forces of ibn-Saud. Pop. (est.), 8,000. J. E. F.

**TAIHOKU** or **TAIPEH** [taihoku, tai′be′], a city at the northern end of Formosa (Taiwan), the capital of Taiwan Province and the largest city on the island, located on the east bank of the Tansui River, 18 mi. southwest of Kiirun, the leading seaport of Formosa, and 13 mi. southeast of the mouth of the Tansui. Taihoku was a political center from

the time Taiwan became a part of China during the Yüan Dynasty (1206-1368), though Chinese rule was administered either from the Pescadores Islands, in the Formosa Strait, or from Fukien Province. Formosa was proclaimed a province of China in 1885, and a viceroy was sent to administer the island from Tainan, in the southwest. The Japanese, to whom the island was ceded under the Treaty of Shimonoseki in 1895, used Taihoku as the site of their director general's office. During World War II the city was damaged by Allied bombing raids, and at the end of the war a Chinese administrator, by virtue of the Cairo Declaration of Dec. 1, 1943, ruled the island from Taihoku. In December 1949 it was made the provisional capital of the Chinese Nationalist government when the government fled from the Chinese mainland.

Taihoku is built on a broad plain surrounded by forests. The climate is tropical and humid, with a mean temperature of 70° F., and an average annual precipitation of 84 in. The typhoon season, from August to December, proved disastrous to the city in 1911, when many buildings were destroyed by the strong winds. Sites of interest in the city include the zoological garden, the botanical garden, the national museum, the Confucian temple, and the Temple of the Goddess of Mercy. Educational institutions include the National Taiwan University and the Taiwan Provincial Teachers' College. Tea manufacturing, sugar refining, and fruit canning are the city's chief industrial activities. Taihoku is on the railroad connecting the larger Formosan cities, and it has international air-line connections. Pop. 1947, 326,407. A. C. T.

**TAIKWA REFORM.** *See* JAPAN (*History*).

**TAILORBIRD,** any one of a number of species of small (5 in.) Old World warblers combined in the genus *Orthotomus* of the family Muscicapidae, or insect eaters. They occur in the Asiatic tropics from India to the Philippine Islands. Their bills are long and straight. The graduated tails of the males are longer in summer than in winter. Plumage is usually gray or green above, with the crown rufous, and whitish or yellowish beneath. Some tailorbirds are little-known forms of the forests; others are familiar garden species. They are of especial interest for their remarkable nests, made from growing leaves stitched together with cobweb and vegetable fiber. Using her bill as a needle, the female passes the thread back and forth, knotting the ends, until a purselike structure is formed, within which the eggs are deposited. H. G. De.

**TAIMYR.** *See* TAYMYR (*Dolgano-Nenets*).

**TAINAN** [tainɑn], a city in western Formosa (Taiwan), 223 mi. southwest of Kiirun. The city, the third largest on Formosa, is 3 mi. from its seaport, Ampin, with which it is connected by railway. Tainan was settled by Chinese immigrants in 1590, but was occupied by the Dutch for the first half of the seventeenth century. At the end of the Ming Dynasty (1368-1644), a severe famine occurred in Fukien Province, compelling thousands of its people to seek a living on Formosa. The viceroy of Fukien provided the immigrants with shipping accommodations and also awarded each refugee "three ounces of gold and one head of ox" as encouragement to reclaim the "neglected island" of China. Conflict with the Dutch was avoided, since the Chinese restricted themselves to farming outside the city. When the general of the Ming Dynasty, Cheng Ch'eng-kung (Koxinga), captured Tainan from the Dutch in 1661, he changed the name of the city from Cheh Ching Lou to Tungtu ("Eastern Capital"). His son Cheng Ching renamed it Tung Ling, and during the reign of the Manchu emperor Kuang Hsü (1875-1908) the name was changed to Tainan ("South of Taiwan").

Tainan has the largest number of temples of any Formosan city, including the Fah Hwa Sze dedicated to the Buddhist saint, the Confucian Temple, the Kwan Kung Tze dedicated to the Chinese national hero of the period of the Three Kingdoms, and, the most revered of all, the shrine dedicated to Cheng Ch'eng-kung. Other places of interest include the Museum of Natural History, the industrial museum of native products, and the tropical Tainan Park. Taiwan College of Engineering is located in the city.

Tainan is situated on a relatively flat coastal plain and has a tropical climate, with a mean temperature of 71° F. and an average annual rainfall of 48 in. The region is chiefly agricultural, and tropical fruits are important. There are sugar and rice mills, alcohol stills, and local trading and manufacturing establishments in the city. It is on the railroad connecting the chief Formosan cities. Pop. 1947, 142,183. A. C. T.

**TAINE, HIPPOLYTE** [tɛ′n] (1828-1893), French historian, critic, and philosopher, was born at Vouziers, in the Ardennes, Apr. 21, 1828. He attended the Collège Bourbon and the Ecole Normale in Paris. His doctor's thesis,

*HIPPOLYTE TAINE*

FROM AN ENGRAVING BY GEORGE E. PERINE

COURTESY OF THE NEW YORK PUBLIC LIBRARY

*Les Sensations* (1856), was refused at the Sorbonne because of its materialistic doctrine. Taine then substituted another thesis, *La Fontaine et ses fables* (1860), which remains to this day the best study on the fabulist. His *Essai sur Tite-Live* (1856) had already stated some of the fundamental ideas in Taine's literary criticism, notably that of the dominant faculty, which in Livy is found to be the oratorical gift. His *Idéalisme anglais* (1864) and *Positivisme anglais* (1864) are excellent studies of Thomas Carlyle and J. S. Mill, respectively. But Taine's most important work in literary criticism is the *Histoire de la littérature anglaise* (1863). His complete theory of literary criticism, formulated in the introduction, finds in that book its widest application. He maintains that literature, like every other manifestation of human activities, is a necessary product, that it is determined by three factors—race, milieu, and moment—to which must be added an element personal to each author, his dominant faculty. He applied the same principles to the history of art (*Philosophie de l'art,* 1865-1867), which he taught for more than twenty years at the Ecole des Beaux-Arts. And he

attacked the spiritualistic philosophers of the nineteenth century in *Les Philosophes classiques au XIX siècle* (1857). *De l'intelligence* (1870) is a positive statement of his philosophy, giving a materialistic and deterministic explanation of the world, according to which all knowledge proceeds from sensations. Teaching that all psychological phenomena are only physiological phenomena, this book became the bible of Naturalism and wielded a decisive influence on French thought at the end of the nineteenth century. In *Les Origines de la France contemporaine* (I, *Ancien régime;* II, *Révolution;* III, *Nouveau régime,* unfinished, 1875-1894) Taine considered historical developments as the inevitable results of given causes. He exhibited a violent dislike for the French Revolution and attempted a rehabilitation of the old French monarchy, in spite of its acknowledged abuses. Taine is also the author of a novel, *Notes sur Paris, vie et opinions de M. Frédéric-Thomas Graindorge, de Cincinnati, U.S.A.* (1868), which is a satire of contemporary customs. Taine's theories of literary criticisms and of history are undoubtedly too rigid, embodying as they do extremes of positivism and pessimism. But his influence was great on such writers as Zola and Maupassant, and he deserves considerable praise for the systematic approach of his method, for his personal integrity, and for his devotion to what he considered the truth. Taine was created an honorary D.C.L. of Oxford in 1871 and in 1878 was elected a member of the Académie Français. He died in Paris, Mar. 9, 1893. F. V.

**TAINO.** *See* Indian Tribes, South American (*Principal Linguistic Families*).

**TAIPEH.** *See* Taihoku.

**TAIPING REBELLION** [tai′pɪ′ŋ] (1850-1864), the most important of the nineteenth-century Chinese risings against the Manchu Dynasty. Hung Hsiu-ch'üan, who had failed his civil-service examinations and in his youth had had a serious illness accompanied by visions, was inspired by Protestant missionary tracts to preach to and assume leadership of a group of professing Christians in Kwangsi and Kwangtung provinces, styling himself the Brother of Christ. Later he preached the T'ai P'ing Kwoh (Heavenly Dynasty of Perfect Peace), calling himself T'ien-wang (Heavenly King). His followers believed he had been sent to redeem the land of China from worship of idols as well as to replace the Manchu Dynasty with the Taiping.

Hung Hsiu-ch'üan led the first rising in Kwangsi Province in July 1850, plundering and ravaging westward into Yünnan Province. In April 1852, after a period of further organization, he advanced northward through Hunan and Hopeh provinces and then down the Yangtze River to Nanking, which was captured in March 1853. Once established in Nanking, he sent northward an army which almost reached Tientsin and other armies south into Anhwei, Honan, Hupeh, and Kiangsi provinces, where they established isolated strongholds after ravaging the countryside. The government that was established combined a rigidly enforced form of Christianity with many socialistic features, but it was poorly organized and administered. The loss of some of the more capable leaders delivered Nanking into incompetent hands. What might have been a revolution for which the nation was ready degenerated into factional quarrels between jealous rivals for power, culminating in a purge in 1856 which considerably weakened the movement. Moreover, the conservative Confucian literati and the wealthier classes preferred to support the Manchu Dynasty, which to them stood for stability. After 1858 abler leaders emerged, particularly Li Hsiu-ch'eng, who regained lost territory in central China and moved into the rich coastal provinces of Kiangsu and Chekiang in 1859 and 1860.

When Taiping forces threatened Shanghai, they were opposed by a mixed force of Europeans and Chinese imperial troops. The eventual suppression of the rebellion was largely due to Tsêng Kuo-fan, a Hunanese scholar and military leader. Under his direction, Changsha and Wuchang, both in Hupeh Province, were retaken and Kiangsi Province was cleared. In 1857 Tsêng assumed command of the imperial forces in Chekiang and, assisted by Tso Tsung-t'ang and Li Hung-chang, pushed the rebels far to the west. By the spring of 1862 Tsêng was able to turn his attention to Nanking. Reinforced by the Ever-Victorious Army, commanded first by the American Frederick Townsend Ward and after his death by the British Charles George Gordon, the imperial army advancing from Shanghai laid siege to Nanking. At the same time Tso Tsung-t'ang went southward to pacify Chekiang Province, and Gordon and Li Hung-chang cleared the territory north of Nanking. On June 30, 1864, T'ien-wang, viewing all as lost, committed suicide. On July 19 Nanking was taken by assault, bringing the rebellion virtually to an end. The destruction wrought was very great throughout the territory involved in the rebellion, and the benefits were few. W. J. H.

**TAIRONA.** *See* Indian Tribes, South American (*Other Linguistic Groups and Tribes*).

**TAI SHAN** [tai′shɑ′n], the holiest of the five sacred mountains of China, rising at the center of Shantung Province near the city of Taian and 50 mi. south of Tsinan, the capital of Shantung. The Tai Shan, on which the legendary Emperor Shun (c. 2255-2205 B.C.) offered sacrifice to heaven, and which is often referred to as the Eastern Peak of Heaven, is 5,048 ft. high. The main route from the foot to the summit is about 15 mi. in length, traversed for the most part by a flight of 6,300 stone steps, roughly divided into three sections. The whole course is marked by I Tien Men (First Heaven Gate) at the foot, Chung Tien Men (Middle Heaven Gate) in the middle, and Nan Tien Men (South Heaven Gate) on the top. On the mountain are hundreds of temples, numerous scenic spots, and thousands of stone tablets bearing the calligraphy of scholars, poets, and emperors of practically all dynasties. A. C. T.

**TAISHO.** *See* Yoshihito.

**TAIWAN.** *See* Formosa.

**TAIYUAN.** *See* Yangkü.

**TAJIKS.** *See* Asiatic Tribes (*Indo-Iranian*).

**TAJ MAHAL** [tɑ′j məhɑ′l], at Agra, in north central India, the crowning jewel of Indo-Islamic architecture. A Mogul ruler, Shah Jahan, erected the monument as a tomb for a beloved wife, Arjumand Banu, better known by her title of Mumtaz Mahall or Taj Mahal (Crown of the Palace). In 1631 she died after bearing fourteen children in eighteen years. The construction of the tomb, begun the following year, employed some 20,000 workmen for nearly twenty years.

The tomb is the focal point of a vast rectangle, two thousand feet long and one thousand feet wide. One short side of this composition, that on the north, runs along the bank of the Jumna River. The southern third of the area includes service structures and ends at a monumental gateway leading into the walled section, which comprises the major part of the

rectangle. Within the walls is a fragrant garden, one thousand feet square and bisected along its axis by a narrow, reflecting pool. Across the entire river side is a raised platform with high minarets at its four corners. At the west side of the platform is a mosque and at the east a reception hall or guest house.

The tomb, at the center of the platform, is a square in plan, with chamfered corners. Within the considerable thickness of the walls is a circumambulatory corridor marked by octagonal chambers within each corner angle. At the center of the plan is the octagonal tomb chamber, crowned by a shallow dome and entered through lofty portals in each face of the structure. This chamber contains the cenotaphs of Taj Mahal and Shah Jahan, surrounded by a pierced marble screen, while the actual burials are in a crypt directly below the chamber. On the exterior, the lofty arched portal in each face is flanked by two stages of niches, and the structure is crowned by a bulbous dome which rises far above the shallow inner dome of the tomb chamber. Simple proportions dictate plan and elevation relationships: the width of the structure equals its total height, and the distance from the floor level to the parapet over the arched portals is just one half the total height.

On both the exterior and interior the structural core is covered with white marble decorated with designs inlaid in semiprecious stones. The infinite variety and richness of detail and the consummate skill displayed in the execution make the structure unique in its general class. The structure seems to mirror the mood of the skies: at sunset the marble assumes a rosy hue.

Designs for the tomb were submitted by the leading architects of the Mogul empire. The one chosen for execution was possibly by a Persian, Ustad Isa. The plan is quite similar to that of a monument to an earlier Mogul ruler, Humayun, erected at Delhi in 1564 after the designs of a Persian architect, and the general architectural type may be traced to still earlier examples in Turkestan and northern Iran. *See also* Mohammedan Architecture. D. N. W.

**TAJO.** *See* Tagus.

**TAKAMATSU** [takamatsu], the capital of Kagawa Prefecture, situated on the northern tip of Shikoku Island, Japan, facing the Inland Sea. The city has a mild and pleasant climate. The winter temperature averages about 40° F., and the season is fairly dry with considerable sunshine, while the summer average is between 75° and 80° F., with considerable humidity. With only 40 to 60 in. of rain annually, the region is too dry to be a major rice-producing area, but some rice, barley, buckwheat, rye, sweet potatoes, and mulberry trees are grown. The hinterland is heavily forested, and some lumbering is carried on; paper, lacquer, and salt are produced, and fishing is an important activity. Takamatsu is a flourishing transshipment and transportation point and is the center of trade between Honshu, the main island, and Shikoku. Trade is carried on by railroad to all parts of Shikoku as well as by coastal shipping to Kyushu and Honshu. Ritsurin Park, comprising about 134 acres, is one of the finest in Japan. Pop. 1954, 124,557. J. E. F.

**TAKAOKA** [takaoka], a city located at the base of the Noto Peninsula on the central west coast of Honshu Island, Japan. It lies about 15 mi. west of Toyama, in Toyama Prefecture, on the Imisu River. Takaoka has wet, foggy, and cloudy winters, with considerable snowfall and temperatures averaging about 35° F.; the summer season is warm and humid, with an average temperature of 78° F. The precipitation varies between 60 and 80 in. annually, most occurring during the winter season. Takaoka changed from a small village to a feudal castle site in 1609, when Toshinaga of the Maeda clan built Takaoka Castle. It has since become an industrial city specializing in hardware and bronze, dye, lacquer ware, cotton spinning, and textiles. It is also a center of the rice trade. Pop. 1954, 123,925. J. E. F.

**TAKASAKI** [takasaki], a city in central Honshu Island, Japan, 65 mi. northwest of Tokyo. It is located in Gumma Prefecture near the upper course of the Tone River, at the western edge of Kwanto Plain. Takasaki has an almost continental climate, with warm summers and cool winters. The average annual temperature is about 54° F. The major crops of the area are rice, mulberry trees, tea, tobacco, vegetables, millet, and buckwheat. The city is a rail junction, and has silk and cotton mills; machine tools and bamboo and other wooden wares are also produced. Pop. 1952, 97,900. J. E. F.

**TAKELMA.** *See* Indian Tribes, North American (*North Pacific Coast*).

**TAKIN** [ta′kin], a heavily built wild mountain goat, *Budorcas,* which inhabits the higher parts of the eastern Himalayas, eastward to the border of Kansu Province of western China. In the west, the shaggy hair of the takins is dark brown, but the color becomes progressively paler until, in the eastern part of the range, it is almost yellowish white. The horns are sharp and bend abruptly backward. A large set spreads 16 in., and each horn is about 20 in. long. When fully grown, the takin weighs 500 to 600 lb. In summer, takins gather in large herds and frequent dense thickets of bamboo and rhododendron near the timber line. They descend into the sheltered valleys in winter. V. H. C.

**TAKLAMAKAN** [taklamaka′n], a desert of central Asia, in the Tarim Darya (River) Basin in the Chinese province of Sinkiang, formerly Chinese Turkestan. The Tarim Darya borders the desert on the north, and the Altyn Tagh and the Kunlun Mountains are on the south. Taklamakan is entered by several rivers, including the Cherchen, the Keriya, and the Khotan. It also has several lake areas, including the Lop Nor (Lop Lake), which has twice shifted its basin. Since the soil is good, the region could become agricultural if irrigation facilities were developed. The climate is an extreme continental type, with almost no rainfall, sub-zero winters, and high temperatures in the summer. The desert is practically uninhabited except along the southwestern and northwestern borders, where there are oases such as Sufu (Kashgar), Soche (Yarkand), Qarghaliq or Karghalik (Yehcheng), and Hotien (Khotan), on the southwest, and Uch Turfan (Wushih), Akosu (Agsu), and Kucha (Kuche), in the northwest. Ancient trade routes followed these lines of oases. Although the area belongs to China, most of the inhabitants are Turko-Moslems. J. E. F.

**TAKOMA PARK** [təkómə], a city in Montgomery Co. and Prince Georges Co., in southern Maryland, located on Sligo Creek, at the northern boundary of the District of Columbia, of which it is a suburb. It was chartered in 1890 and has the mayor-council form of government. The chief activities of the community center about the headquarters of the Seventh-day Adventists in the city. Takoma Park is the seat of Washington Missionary College operated by that group. Washington Sanitarium is to the northeast, just

across Sligo Creek. Transportation is provided by the Baltimore and Ohio Railroad. Pop. 1950, 13,341.

**TAKORADI** [tɑ′korɑ′di], a seaport, opened in 1928, about 113 mi. southwest of Accra on the British Gold Coast. It is the only deep-water harbor between Sierra Leone and Nigeria. In 1953 the harbor facilities were vastly expanded. It can handle large ships up to 40 ft. draught. The main export is manganese ore. Takoradi, united in 1946 with Sekondi to form one municipality, has railway connections with the capital, Accra, via Kumasi. Pop. 1948, 17,800; Sekondi-Takoradi, 44,557. R. G. W.

**TALAING.** *See* Asiatic Tribes (*Other Linguistic Families*).

**TALC** or **STEATITE** [sti′ətait], a hydrous magnesium silicate, $Mg_3Si_4O_{10}(OH)_2$. It occurs both massive and foliated. Rock consisting dominantly of talc is called soapstone. Talc is the softest of minerals (hardness of 1) and has a soapy feel; it is also sectile. It is a secondary mineral formed by the hydration of such primary magnesium silicates as olivine and pyroxene, or of other secondary minerals such as serpentine. The agent of alteration may be either ground or magmatic waters. The resulting deposits are lenticular, but some individual lenses are very large. Talc is a mineral of many uses. Its white color, ready pulverization, and low cost make it a good filler in paint, paper, ceramics, rubber, textiles, linoleum, composition roofing and flooring, oil cloth, and many other substances. The slippery feel makes it useful in foundry facings and cosmetics. Massive talc can be shaped and heated to form refractories and electric insulators. Soapstone, because of its composition and character, can be sawed into desired shapes for use as laboratory table tops, sinks, switchboards, fireless-cooker stones, and griddles. This material was used by the ancients for carvings. The United States is the leading producer of talc and soapstone. The most important talc states are New York, North Carolina, California, and Vermont; all of the soapstone comes from Virginia. Other countries producing considerable tonnages of these materials are Manchuria, France, and Italy, with Canada, India, Norway, and Spain appearing in the production statistics as lesser sources. K. K. L.

**TALCA** [tɑ′lkɑ], capital of the agricultural and wine-producing province of Talca, Chile, on the Claro and Piduco rivers, 155 mi. south of Santiago. The city is the most important in the central valley and one of the largest manufacturing centers in the country. The principal products are shoes, tobacco, flour, paper, beds, liquor, and rubber tubes. The city, founded in 1692, was entirely rebuilt after earthquakes in 1742 and 1928. Pop. (off. est. 1945), 43,749. S. G. I.

**TALCAHUANO** [tɑ′lkɑwɑ′no], the port of Concepción, Chile, located 5 mi. from that city. It is on Talcahuano Bay and has the best harbor in Chile. An important grain and export center, it is a port of call for steamers. Pop. (off. est. 1945), 33,423. S. G. I.

**TALE OF A TUB, A,** a satire by Jonathan Swift, published in 1704 but probably written about 1697. Swift tells us that his satire is directed against "the numerous and gross corruptions in religion and learning." The corruptions in religion are dealt with in the story of three brothers, Peter, Martin, and Jack, and what they did with the coats left to them by their father with strict injunctions that the coats were not to be altered in any particular. Peter represents the Roman Catholic Church, Martin the moderate Protestantism of the Church of England, and Jack the fanatical Protestantism of the dissenting sects. The story is told with brilliant wit, sometimes open to charges of irreverence and indecency, in alternating "sections" of the book. The intervening sections are devoted to "digressions" in which Swift deals with the "corruptions in learning." Most famous of these is the profoundly ironical "Digression on Madness" (Section IX). R. K. R.

**TALE OF IGOR'S CAMPAIGN, THE** (*Slovo o Polku Igoreve*), a Russian prose poem dealing with an expedition of Prince Igor Svyatoslavich against the Polovtsy in 1185. It falls into three parts: (1) a narrative of the campaign and of the defeat and capture of Igor; (2) a lyrical interlude, containing a prophetic dream by Grand Prince Svyatoslav, uncle of Igor; poetic appeals to various Russian princes; and a lament by Igor's wife, Yaroslavna; and (3) a narrative of Igor's escape from captivity. The first and third parts tell of events related briefly in the *Kiev Chronicle.* The *Tale* came to light in 1795, when Count A. I. Musin-Pushkin announced that he had found it in a bound volume of manuscripts purchased from the Archimandrite of the Spaso-Yaroslavsk Monastery. It was published in 1800; the manuscript perished in the burning of Moscow in 1812. Most Russian scholars accept the *Tale* as the finest poetic work of early Russian literature, composed soon after the events of which it tells, but there are some students who have denounced it as an eighteenth-century forgery. Two items in the controversy may be mentioned here. In general there are few points of contact between the *Tale* and undoubted productions of the Russian Middle Ages. But a work on the battle which took place in 1380 between Grand Prince Dmitri of Moscow and the Tatars under Mamay, preserved in two main redactions, distinctly resembles it in both substance and phrasing: it is safe to say that either the writer of the *Zadonshchina* (*The Campaign beyond the Don*) knew the *Tale* and made rather clumsy attempts to imitate it, or else some person of literary talent read the *Zadonshchina,* was impressed by it, and used it as a chief source for a clever forgery, embroidering on its style. Furthermore the *Tale* contains allusions, of a sort elsewhere unparalleled, to Russian heathen deities, though Christianity had become established in Russia by the close of the tenth century. These allusions may be due to living popular tradition or they may be due to eighteenth-century pseudoclassicism. The question of authenticity is not settled, but among scholars of Russian nationality there are few skeptics. G. R. N.

**TALE OF TWO CITIES, A,** a historical novel by Charles Dickens, was written in 1859 as a weekly serial for the author's newly founded magazine, *All the Year Round.* The two cities are London and Paris, before and during the French Revolution. For his background material Dickens relied heavily on Carlyle's history of the period; under the pressure of weekly installments he found it advisable to restrict the number of characters in the novel. Its highly dramatic climax, in which Sidney Carton, out of love for Lucie Manette, rescues her husband from prison and takes his place at the guillotine, made the stage adaptation of the story the most steadily popular play ever based upon a Dickens novel. DeL. F.

**TALES OF A WAYSIDE INN,** a series of narrative poems, published in three parts (1863, 1872, 1874) and later collected in one volume (1886), by Henry Wadsworth Longfellow. The author used the framework pattern made

familiar by Chaucer and Boccaccio. Supposed to be stories told in turn by a group of congenial companions as they sit about the fire at a rural inn at Sudbury, near Boston, the twenty-one poems deal with a variety of themes, ranging from local American history to old stories based on Boccaccio, the Talmud, and legends which Longfellow had collected in Europe. Best known among them is *Paul Revere's Ride*. Others include *The Legend of Rabbi Ben Levi, The Saga of King Olaf, King Robert of Sicily,* and *The Birds of Killingworth.* L. L.

**TALES OF HOFFMAN, THE.** *See* CONTES D'HOFFMAN, LES.

**TALI.** *See* AFRICAN PEOPLES.

**TALISMAN.** *See* CHARM.

**TALISMAN, THE,** one of Sir Walter Scott's *Tales of the Crusaders,* first published in 1825. The story is laid in Palestine about 1191, during the Third Crusade. A truce is declared between the troops of Richard and Saladin's Saracens, and it is during this truce that the events of the story occur. Saladin helps the hero, Kenneth of Scotland, to redeem himself after he has lost the English banner that he was guarding. Kenneth is forced to become Saladin's bond servant, but eventually returns as the Knight of the Sleeping Leopard, kills the thief of the banner, Conrade of Montserrat, and wins Lady Edith of Plantagenet. Saladin and the Saracens prove far more interesting than the English or Scotch. The "Talisman" is a pebble, possessed by Saladin, which has miraculous healing powers. W. Ru.

**TALLADEGA** [tælədi′gə], a city in east central Alabama, the county seat of Talladega Co., situated 60 mi. east of Birmingham, at the foot of the Blue Ridge Mountains, in an agricultural area devoted to the growing of cotton. Rich and varied natural resources of the region include marble similar to the Italian in quality and beauty; gold, brown, and gray iron ore; bauxite; talc; china clay; dolomite; and red and yellow ocher. Onyx Cave and mineral springs are natural features of the district, and Talladega National Forest and Cheaha State Park containing Cheaha Mountain, 2,407 ft. above sea level and the highest point in Alabama, are near by. The townsite was formerly the property of the Creek Indians, and its name is Indian for bordertown since it was on the edge of the Indian lands. In 1813 at the Battle of Talladega Andrew Jackson defeated a force of hostile Creek Indians. The community, incorporated as a city in 1835, has the commission form of local government. It is the seat of Talladega College for Negroes and the Alabama State Institution for the Deaf and Blind. The Louisville & Nashville, the Southern, and the Atlantic Coast Line railroads furnish transportation. Besides cotton textiles, the town's chief manufacture, the local factories produce pine and hardwood lumber, pipe and pipe fittings, textile machinery parts, cottonseed oil and meal, and plumbing supplies. Pop. 1950, 13,134.

**TALLADEGA COLLEGE** [tælədi′gə], an accredited, coeducational, privately controlled college of arts and sciences for Negroes, affiliated with the Congregational Church and supported in part by the American Missionary Association. The college occupies a 300-acre campus in the city of Talladega, Ala. Instruction was begun in 1867 and a charter was issued two years later. The A.B. in liberal arts and the B.Mus. are offered. Fraternities and sororities are in existence on the campus. Dormitories and dining halls are provided for both men and women, and all out-of-town students must live either in dormitories or in approved houses. Scholarship assistance is generous and a loan fund has been established. *For statistics see* COLLEGES AND UNIVERSITIES. J. R. To.

**TALLAHASSEE** [tæləhæ′si], the state capital and the county seat of Leon Co., in northwestern Florida, about 160 mi. west of Jacksonville, and about 30 mi. north of the Gulf of Mexico. The city is a trading center for a timber and fertile farming region, but its chief activities are political and educational. An Indian name meaning old town, Tallahassee was the capital of the Apalachee Indians when Hernando de Soto and his men reached it in 1539. Two Franciscan friars came in 1633, and Fort San Luis was built about 1640 as the headquarters for seven missions. In 1824 the city was chosen as the state capital, the first legislature meeting in a log building. In 1825 the city charter was granted. Tallahassee is the seat of the Florida State University and the Florida Agricultural and Mechanical College for Negroes. Sites of interest include the state capitol (completed in 1845), the governor's mansion, the Martin Building with the museum of the State Geological Society, the Presbyterian Church, the Columns, the Groves, the May Oak where the May Festival is held, ruins of Fort San Luis, and the grave of Prince Achille Murat. The city is served by the Seaboard Air Line Railroad and planes of the Eastern and the National airlines. The factory output of Tallahassee includes naval stores, lumber products, feed, packed pecans, mattresses, and insecticides. The farms in the region raise livestock, corn, sweet potatoes, and cotton. Pop. 1950, 27,237.

**TALLAHATCHIE RIVER** [tæləhæ′tshi], 301 mi. long, one of the headwaters of the Yazoo River. It rises in Tippah Co., northeastern Mississippi, flows southwestward, and is joined by the Coldwater River in Quitman Co. and by Yalobusha and Greenwood rivers in Leflore Co., west central Mississippi. These rivers combine to form the Yazoo River. The Tallahatchie is a sluggish, narrow stream in summer, but it widens to 300 ft. or more during winter floods, which have caused great destruction. The Sardis Dam, in Panola Co., now helps to control floods of the river. The Tallahatchie has been improved for small-boat navigation as far as Minter City, Leflore Co. The river drains 3,500 sq. mi. of cotton-growing land. J. E. F.

**TALLAPOOSA RIVER** [tæləpu′sə], 268 mi. long, one of the headwaters of the Alabama River. It rises in Paulding Co., northwestern Georgia, and flows 56 mi. southwest into northeastern Alabama, where it bends southward and then west to join the Coosa River north of Montgomery, Ala. In Tallapoosa Co., Ala., it enlarges to form Martin Lake. The river crosses the fall line at Tallassee, Ala., dropping 60 ft. in a series of rapids and falls. The lower part of the river is navigable. J. E. F.

**TALLENSI.** *See* AFRICAN PEOPLES.

**TALLEYRAND-PÉRIGORD, CHARLES MAURICE DE (PRINCE DE BÉNÉVENT)** [ta′le′rã′] (1754-1838), French bishop, politician, and diplomat, was born in Paris, Feb. 13, 1754. Neglected by his parents, who were members of the court of Louis XV, he was placed under the supervision of his grandmother in Périgord, in southwestern France. Later he attended the Collège d'Harcourt in Paris and, as a crippled second son, ineligible for the army, was destined for the Church. Early in 1789 he was appointed bishop of Autun and not only represented his see in the Estates General but

also drafted the instructions or *cahier* for the clergy of his area. In the Estates General and the National Assembly (May 5, 1789-Sept. 30, 1791) he favored creation of a strong constitutional monarchy. He also advocated (October, 1789)

*PRINCE CHARLES MAURICE DE TALLEYRAND-PÉRIGORD*

COURTESY OF THE NEW YORK PUBLIC LIBRARY

confiscation of the Church lands and took the oath supporting the civil constitution of the clergy which tended to nationalize the Church. He disapproved the dethronement of Louis XVI on Aug. 10, 1792, but he had already taken precautions for his personal safety on Sept. 14, 1792, and left France for England, where he hoped to be of service in preventing war between France and Great Britain. He foresaw correctly that the opening of the Scheldt Valley would prejudice peace between the two nations. After war broke out, on Feb. 1, 1793, he was forced to leave England. He sailed for the United States on Feb. 3, 1794, and spent approximately two years in that country, traveling, studying commercial conditions, and serving as land agent for potential emigrants. Returning to France early in 1796, Talleyrand ingratiated himself with the Directory (1795-1799) and was appointed minister of foreign affairs. During two years of service (July 1797 to July 1799) he handled, among other problems, negotiations for peace with Great Britain. He favored Napoleon Bonaparte's cause before the *coup d'état* Nov. 9, 1799, which brought the latter to power. Napoleon reappointed Talleyrand to the post of foreign minister in December 1799, and Talleyrand served in this capacity until after the Treaty of Tilsit with Russia, July 7-9, 1807. Thereafter, he cooled toward the imperial regime and secretly worked for the restoration of the Bourbon dynasty. In return for his support, Talleyrand represented Louis XVIII at the Congress of Vienna, where his adroit diplomacy succeeded in gaining moderate terms for defeated France. In September 1815 he retired from the ministry and, with the exception of his service as ambassador to Great Britain (1830-1835) during the early years of the reign of Louis Philippe, did not again participate in public life. He died in Paris on May 17, 1838. R. M. Br.

**TALLINN** [ta'llɪn], formerly Reval or Revel, a seaport and the capital of the Estonian S.S.R. of the Soviet Union, located on the northwest coast of Estonia, about 200 mi. southwest of Leningrad, at 59° 25′ N. lat. and 24° 45′ E. long. It is picturesquely situated on the deep, wide-open Tallinn Bay on the southern coast of the Gulf of Finland. The lower town lies on a sandy coastal plain, while back of it on a limestone escarpment, 150 to 250 ft. higher, is the upper town.

*OLD WORLD CITY OF TALLINN, CAPITAL OF THE ESTONIAN S.S.R. OF THE SOVIET UNION, WAS FOUNDED BY THE DANES IN 1219.*

EWING GALLOWAY

**History.** A Danish settlement existed on the site as early as 1093; in 1219, after destroying the old Estonian fortress of Lindanissa, the Danes built a fortress in the town. It was controlled at various times between the thirteenth and sixteenth centuries by the Livonian Knights, the Danes, the Teutonic Knights, and Sweden, having become a member of

the Hanseatic League in 1284. After undergoing a serious conflagration in 1433, pestilence in 1532, bombardment by ships from Lübeck and Denmark in 1569, and prolonged though unsuccessful sieges by the Russians in 1570, 1571, and 1577, its trade was largely destroyed. It surrendered to Peter the Great in 1710 and prospered under him and his successors, who fortified it as a military port. It was unsuccessfully attacked by the Swedish fleet in 1790 and blockaded by the British in 1809 and again by the British and French in 1854 and 1855. The port became capital of the new republic of Estonia in 1919 and retained its status in the Soviet republic established in 1940. Tallinn was captured by the Germans and heavily damaged in World War II; it was liberated by Soviet troops on Sept. 22, 1944, and returned to Soviet control.

**Economic Activities.** Tallinn is a terminus of main railway lines from Leningrad and Moscow and also serves the rail network of the western Soviet Union. An important medieval port, the city again became a busy Baltic port under the Russians before 1918; its harbor, kept open by icebreakers, handled approximately one-fifth of Russian imports, including all cotton and many other products for the Moscow industrial area. It regained its trade during the early 1930's after a setback following World War I, but it received severe damage to its facilities in World War II. Exports include textiles, grain, timber, paper, and cement; imports include foodstuffs, cotton, and coal. There is also trade in flax, hides, and bristles. Industrial establishments include iron and steel works and food factories (both largely ruined by the Nazis in World War II), cotton mills, sawmills, pulp mills, and shipbuilding and repairing yards. Fishing and fish canning are leading industries. Pop. (est. 1950), 250,000. C. C. H.

**TALLITH.** *See* TEPHILLIN.

**TALLOW TREE,** also known as vegetable tallow, a small tree, *Sapium sebiferum,* 25 to 30 ft. high, of the spurge family. A native of China, it is naturalized and cultivated in the southern United States and other tropical lands. It has broad oval leaves, beautifully red-colored in age, and small flowers in terminal spikes. Within the thick fruiting capsule are large white seeds having a waxy covering, used for making candles and soap, and for dressing cloth. The name is sometimes given to the candlenut. J. C. Wis.

**TALLULAH** [təlu′lə], a city in northeastern Louisiana, the parish seat of Madison Parish, situated on the banks of the winding Roundaway Bayou, 55 mi. east of Monroe. Cypress and oak timber are found in this region. Cotton is the chief crop, and other agricultural products are corn and hay. Tallulah has local manufactures of lumber, soft drinks, and cottonseed-oil products. It is governed by a mayor and council. The community is served by the Illinois Central and the Missouri Pacific railroads. Pop. 1950, 7,758.

**TALMUD** [tæ′lmɑd], a body of rabbinic literature, consisting of the Mishnah (a compilation of laws) and the Gemara (the discussions and expositions revolving around the Mishnah). There are actually two Talmuds, the Palestinian and the Babylonian, each having different Gemara but the same Mishnah text; of the two the Babylonian Talmud is the more important and has received far more attention.

The Mishnah, after its completion in about 200, became the basic text of study in the Babylonian and Palestinian rabbinical academies. Not all of the sixty-three tractates of the Mishnah (which is divided into six orders) have Gemara; in the Babylonian Talmud, for example, only one tractate of the first order is so provided, presumably because the laws in the first order, dealing mainly with agriculture, were inapplicable in Babylonia. The Palestinian Talmud was completed about A.D. 400 and the Babylonian about a century later; the latter, containing approximately 2,500,000 words is about three times as large as the former. The authors of the Mishnah were called *tannaim;* those of the Gemara *amoraim;* and the editors of the Talmud, who flourished immediately after its completion, *saboraim.* The language of the Mishnah is Hebrew and that of the Gemara is Aramaic, with some admixture of Hebrew, but there are dialectal differences between the Palestinian Aramaic and the Babylonian. Among the notable translations of the Talmud, or of parts of it, are a complete English translation of the Mishnah by Herbert Danby (1933); a German translation of the Babylonian Talmud by Lazarus Goldschmidt; French and Latin translations of the Palestinian Talmud; and an English translation of the Babylonian Talmud (Soncino Press, England), completed in 1948.

The material in the Talmud may be classified as Halachic or legal, and Haggadic. The Haggadic portion is extremely varied and includes ethical, legendary, exegetical, historical, homiletic, scientific, and biographical matter. About thirty per cent of the Babylonian Talmud and about fifteen per cent of the Palestinian Talmud consists of Haggadah.

The Talmud represents the Oral Law and is considered, by Orthodox Jews, as authoritative as the Written Law, represented by the Bible. According to tradition, the teachings of the Oral Law are Mosaic in origin and have been transmitted by word of mouth through the centuries. The Talmudic law is in a sense derivative of Biblical law, but to a great extent it reflects the custom and thought of its own times. The Jewish observance of Biblical law is determined by Talmudic interpretation, and all codes of Jewish law are based on the Talmud; hence the Talmud is of prime importance in Jewish religious practice. Occasionally, certain Jewish groups have rejected the authority of the Talmud, notably the Karaites in the Middle Ages; in modern times, Reform Judaism does not consider the Talmud binding in matters of religious observance. Throughout the centuries the Talmud has been the principal, sometimes the sole, subject of study in Orthodox rabbinical schools. An encyclopedic work, encompassing virtually all aspects of human life, the Talmud is also of great interest to students of law, history, religion, ancient culture, language, and literature. See also AMORA; HAGGADAH; HALACHAH; JUDAISM; KARAITES; MIDRASH; MISHNAH; ORAL LAW; TANNA. M. A. G.

**TALUS** [te′ləs], in Greek mythology, a Cretan man of bronze, made by Hephaestus. Talus heated himself red-hot and clasped in his embrace strangers who arrived on the island. When the Argonauts stopped at Crete, he was captured by Castor and Pollux and destroyed by Medea. Talus was also the name of a nephew of Daedalus. *See also* DAEDALUS. G. E. D.

**TAMANDUA.** *See* ANTEATER.

**TAMAQUA** [təmɑ′kwə], a borough in Schuylkill Co., in east central Pennsylvania, situated on both banks of the Little Schuylkill River, 32 mi. north of Reading. Anthracite coal has been mined extensively since its discovery in 1817. Tamaqua was founded in 1799 and incorporated in 1829. It annexed the village of Newkirk in 1920. Tamaqua is gov-

erned by a mayor and council. Transportation is supplied by the Reading and the Lehigh & New England railroads. Manufactures include iron and steel products, women's underwear and dresses, explosives, canned goods, and book covers. Fruit, grain, poultry, and truck farming are carried on in the area. Pop. 1950, 11,508.

**TAMARACK.** *See* LARCH.

**TAMARIN** [tæ′mərɪn], any marmoset of the genus *Leontocebus,* found in South America. A distinctive characteristic of the genus is the length of the canine teeth, which are longer than the incisors. The face is covered with silky hair, the mustache often being of impressive size. The body fur is black, mottled with red or gray. The tail is not ringed, as in typical marmosets. The ears are big, the eyes large, bright, and shiny. Tamarins travel in small groups. They are timid, but show little fear of man, being found even in city suburbs. They occupy woods or scrub growth, where they climb in the manner of squirrels. *See also* MARMOSET.
R. T. H.

**TAMARIND** [tæ′mərɪnd], a tall evergreen tree, *Tamarindus indica,* of the pea family, probably native to southern Asia and tropical Africa, and long cultivated in the tropics of both

COURTESY OF R. S. MATHEWS

*The tamarind tree,* Tamarindus indica

hemispheres as an ornamental, and for its edible fruit. It is successfully grown in southern Florida. The tree grows as high as 80 ft., has a trunk reaching 8 ft. in diameter, and bears pinnate leaves of 20 to 40 oblong leaflets, and loose clusters of pale yellow flowers, veined with red. The plump, reddish-brown pod, 3 to 8 in. long, has a thin, brittle shell and 1 to 12 flat, glossy seeds enclosed in brown pulp. The acid pulp, which contains sugar, is used in cooking, and to make cooling beverages; it has medicinal uses also. The tamarind is a standard article of diet in the Orient, and an important export of many countries. J. C. Wis.

**TAMARISK** [tæ′mərɪsk], a genus, *Tamarix,* of deciduous shrubs and small trees of the tamarisk family, comprising about 75 species native to western Europe, the Mediterranean region, India, and eastern Asia. Several species are cultivated ornamentally for their feathery foliage and profuse bloom; some are used as sand binders and windbreaks, and in seaside plantings. These trees have small, usually scale-like leaves on very slender branches, and showy clusters of pink or white flowers. The French tamarisk, *T. gallica,* a small pink-flowered tree of the Mediterranean region, growing as high as 30 ft., is sparingly naturalized in the United States. *T. mannifera* is known for the "manna" produced on it by the punctures of an insect, *Coccus manniparus.* The Athel tamarisk, *T. aphylla,* a small tree of western Asia having green, pointed twigs, has been widely planted as a windbreak in the California desert region. Dyestuffs and medicinal preparations are produced from several species of tamarisk.
J. C. Wis.

**TAMAROA.** *See* INDIAN TRIBES, NORTH AMERICAN (*Eastern Woodland*).

**TAMAULIPEC.** *See* INDIAN TRIBES, NORTH AMERICAN.

**TAMBOURINE** [tambʊri′n], a musical instrument of indefinite pitch, consisting of one or two parchment heads stretched over a wooden hoop strung with metal jingles. The jingles are set in vibration by striking or rubbing the head of the tambourine or by shaking the whole instrument. Used in southern European folk music since the Crusades, and in Western band and orchestral music since the nineteenth century, the tambourine is modeled after the frame drum which has been played in the Near East, usually by women, for thousands of years. A similar drum, struck with a beater, is the magic-working instrument of Siberian and Amerindian medicine men. W. Li.

**TAMBOV** [tʌmbɔ′f], the name of both a governmental region and the city which is the administrative center of that region, located in the Russian Soviet Federated Socialist Republic, in the western Soviet Union.

**The City.** The city, an industrial community, is situated on a broad lowland in a dissected rolling area, on the nonnavigable Tsna River, 273 mi. southeast of Moscow. Founded in 1636 as a Muscovite frontier fortress, Tambov became an important cereal trade center in the early nineteenth century. The city and surrounding area were largely devastated during the civil conflict between 1917 and 1920. Noteworthy buildings include a seventeenth-century five-domed cathedral, Lutheran and Roman Catholic churches, and two museums. A railroad junction and grain collection center, it has synthetic rubber, thread, and leather and boot industries, machine and tractor shops, motor-repair works, and an electric-power plant. Pop. (est. 1950), 140,000. C. C. H.

**The Region.** Tambov Region or Tambovskaya oblast, an administrative unit of the central R.S.F.S.R., is situated in the Oka-Don lowland near the source of the Tsna River, which flows to the north into the Oka River. The region has an area of about 2,355 sq. mi., the surface of which is flat. Some forests are found along the rivers, but otherwise the region is mostly bare. Cereals, vegetables, hemp, sunflower seed, and coarse tobacco are grown. Livestock trade and horse breeding are also important. Michurinsk (Kozlov), the second city in importance, is a junction for the Moscow-Saratov-Rostov railroad line. Pop. (est. 1954), 1,500,000.
W. S. V.

**TAMBURLAINE** [ta′mbərlen] (Part I 1587, Part II 1588), a poetic drama by Christopher Marlowe, treating the rise of Timur Lenk (died c. 1405) "from a Scythian shephearde" to "a mightye monarque and . . . the Scourge of God." In conception and execution *Tamburlaine* was revolutionary. An almost plotless series of conquests is unified through the dominance of the aspiring hero, who expresses with passionate eloquence, in blank verse of unprecedented vigor and grace, the author's own worship of the Renaissance ideals of power and beauty. Marlowe's iconoclasm

and youthful optimism found a congenial outlet in the career of the Scythian conqueror. Immensely successful, *Tamburlaine* was widely imitated. Despite occasional bombast it brought to English drama the elevation of poetic passion, demonstrated the dramatic value of a great unifying character, and made blank verse the accepted vehicle of Elizabethan drama. P. W. T.

**TAMERLANE, TAMBURLANE,** or **TIMUR LENK** [tæ′mərlen, ta′mbərlen, tɪmʊ′r lɛ′ŋk] (1336-1405), Oriental soldier and conqueror, was born in 1336 at Kesh, 50 mi. south of Samarkand, in Transoxiana (Bukhara). He was descended in the female line from Genghis Khan, and, on the death of his father, became head of the family tribe of Berlas. He allied himself with the governor of Transoxiana, but intrigue obliged him to flee from Samarkand. When pursued, he turned on his enemies and defeated them. He allied himself with his brother-in-law, Amir Husein, but they were forced into the desert. It was during this period that Timur acquired his sobriquet, The Lame, as the result of arrow wounds which left him permanently crippled. Tamerlane, as he became known, and his ally were partially successful from 1363 to 1365, but eventually quarreled and became rivals. In 1369 Amir Husein was besieged in Balkh, forced to surrender, and put to death. Tamerlane, proclaimed sovereign, mounted the throne at Samarkand, assumed the title of Great Khan, and set out to reunite the Mongol conquests of his ancestor, Genghis Khan. From 1369 to 1380, he was engaged in conquering the neighboring states of Jatah to the east and Khiva to the west.

In 1380 he began his campaign into Persia, but his progress was slow. In 1384, after having taken Khurasan in Persia and consolidated his conquests, Tamerlane advanced northwest to the Black Sea. He occupied Azerbaidzhan, crossed the Araks, overran Georgia, and received the submission of the local princes of Kiptchak (that is, southwestern Russia). He then marched to Isfahan in Persia, captured the city, and put most of its citizens to death. Pyramids of skulls were his particular architectural fancy; after the storming of Isfahan he piled up 70,000. Shiraz hastened to surrender, but Toktamish, ruler of the Golden Hordes, successfully opposed Tamerlane and was not overcome until 1395.

In 1398 Tamerlane led his armies into India, an expedition which culminated in a triumphal entry into Delhi. He returned to his capital at Samarkand with great quantities of booty, but soon launched a campaign into Syria and Asia Minor, where he captured Baghdad, Aleppo, and Damascus. At the Battle of Angora (Ankara) in 1402, he defeated the Turkish sultan, Bajazet I, and took him prisoner. After his return to Samarkand, Tamerlane planned an invasion of China, but he was stricken by fever on the way and died at Atrar (Otrar), beyond the Syr Darya, on Feb. 17, 1405. His extensive empire quickly disintegrated, and his Persian domain was soon extinguished by another Turkoman horde. T. R. H.

**TAMING OF THE SHREW, THE** (c. 1595), a play by Shakespeare. This lively comedy shows the author engaged in rewriting an old play which had come into the hands of his company some years earlier. In the main he follows the scenario of his source, but he writes new and vigorous dialogue to bring out the characters of the drunkard Christopher Sly, Katherine, and Petruchio. Katherine, a violent, hot-tempered girl, is given in marriage to an adventurous stranger, Petruchio. In a long and comic struggle between them her self-will is broken by an outrageous but good-humored exhibition of the same quality on his part; the "shrew" is tamed, and becomes a loving, obedient wife. The underplot, drawn from George Gascoigne's *Supposes* (1566), deals with the courtship of Katherine's gentle sister, Bianca. T. M. P.

**TAMMANY HALL.** *See* Societies, Associations, and Organizations.

**TAMMERFORS.** *See* Tampere.

**TAMMUZ** [ta′mmuz], a god of agriculture and the flocks in Babylonian religion. Like the parallel Osiris of Egypt, his cult goes back to earliest Sumerian times. The cycle of Tammuz shows marked similarity between Sumero-Akkadian, Anatolian, and Egyptian myths, which have a tendency to group beliefs and practices around a central deity: Tammuz in Mesopotamia, Osiris in Egypt, Adonis in Syria and the Hellenistic world, and Attis in Asia Minor.

Tammuz was the lover of Ishtar, the goddess of love and fertility, who, at painful cost to herself, brought him back from the lower world after his death. His career symbolized the death of natural vegetation in winter and its rebirth in spring. The annual festival of Tammuz, coming just before the summer solstice, consisted of a period of mourning followed by rejoicing at his return. The Bible (Ezek. viii:14) refers to "the women weeping over Tammuz." The hot summer month of July, *Tammuz* in modern Arabic, was originally named after this deity by the Babylonians. E. J. J.

**TAM O' SHANTER,** a humorous narrative poem by Robert Burns, was written in 1790 at the urging of Captain Francis Grose (1731-1791), to accompany an engraving of the ruins of Alloway Kirk in the second volume of Grose's *Antiquities of Scotland* (1791). Burns himself called *Tam O' Shanter* his "standard performance in the poetical line"; it is one of the finest examples in all literature of the successful mingling of comedy and terror. DeL. F.

**TAMPA** [ta′mpə], a port city, the county seat of Hillsborough Co., on the central west coast of Florida. The third largest city in the state, it is situated on Tampa Bay, at the mouth of the Hillsboro River, and about 25 mi. north of St. Petersburg. Pánfilo de Narváez landed on the shores of Tampa Bay in 1528. Hernando de Soto arrived eleven years later, and, according to legend, he held a parley with the unfriendly Indians under the De Soto Oak, which is located on the campus of the University of Tampa. The hostile attitude of the Indians deterred white settlers until 1823, when a detachment of United States troops established Fort Brooke on the site. The community which developed was incorporated in 1855. The first railroad reached Tampa in 1885, and in 1887 the port was designated an official port of entry. The tourist trade was attracted to the city in 1889 on completion of the $3,500,000, Moorish-style, Tampa Bay Hotel in Plant Park. But it was the opening of the cigar industry in 1886 at Ybor City, which became a part of Tampa within three years, that brought about the city's growth. Tampa gained prominence during the Spanish-American War as the embarkation point for troops bound for Cuba. In 1950 a mayor and council administered the city.

The Tampa Bay Hotel, which has been converted to house the University of Tampa and the Tampa Museum, remains a leading landmark. There is a state tuberculosis sanitarium and a county home and hospital. Near by is the United States Air Force installation, MacDill Field.

Tampa is also a popular winter resort, one of the three leading industrial cities of Florida and one of the most important ports along the Gulf of Mexico. The city is the lead-

ing phosphate shipping point in the country. Other exports include lumber and canned citrus fruits. The Atlantic Coast Line and the Seaboard Air Line railroads provide rail facilities; the Eastern and the National air lines furnish additional transportation. Cigars, especially hand-made Havana cigars, continue to be the predominant product of Tampa's factories. Second in importance is canned citrus fruits, particularly grapefruit. The varied factory output also includes meat products, flour, feed, cement, fertilizer, and cans. Shipbuilding is important, and Tampa derives a large portion of its income from its wholesale distribution. Pop. 1950, 124,681. S. D. M.

*BUSINESS DISTRICT OVERLOOKING THE WATERFRONT AT TAMPA, FLORIDA*

EWING GALLOWAY

**TAMPERE** [ta′mpɛrɛ] (*Swed.* Tammerfors), a manufacturing city and the capital of Häme Province, in southwestern Finland. Located about 100 mi. northwest of Helsinki on the southern shore of Lake Näsijärvi, Tampere is built on the hilly sides of a valley and has straight streets lined with clean, trim buildings. A city hydroelectric plant is powered by the Tammerkoski rapids, where the water flowing between Lake Näsijärvi and Lake Pyhäjärvi drops 54 ft. The city was founded in 1779 but had its great growth after 1819, when the Scottish engineer Finlayson, under a government loan and important special privileges, built there the first cotton mill in Finland. With the development of the wood-pulp process around 1860, the city assumed considerable importance as a paper manufacturing center.

Tampere, the largest industrial city in Finland, and third in population, was the center of activities of the Finnish "Red" Army in the 1918 revolution. The capture of Tampere by the "White" Army under Mannerheim, after a battle lasting from Apr. 3 to 6, 1918, assured the republican character of Finland. During the two Russo-Finnish Wars, 1939-1940 and 1941-1944, the city sustained some damage from bombs. Outstanding for its large factories, Tampere is also noted for its modern St. John's Church (built between 1902 and 1904) with frescoes by Magnus Enckell, for its bridge with sculpture by Väino Aaltonen, and for its Näsilinna Museum. In addition to cotton goods and paper, the city manufactures leather, machines, locomotives, linen, roofing, clothing, and shoes. Tampere has rail connections with all parts of southern Finland and is a center of lake and river boating. Pop. 1951, 101,509. J. E. V.

*Slender palm trees fringe a field of of oil-storage tanks in Tampico, center of Mexico's oil-refining industry.*

G. MYERS FROM GENDREAU

**TAMPICO** [tɑmpi′ko], a Mexican port city on the Gulf of Mexico. Located in the southernmost part of Tamaulipas State, on the Pánuco River, 7 mi. from its mouth, and about 210 mi. northeast of Mexico City, Tampico is Mexico's largest oil center, although the oil fields lie some distance away at Poza Rica. Refineries extend along the southern bank of the Pánuco and process from two thirds to three quarters of all the petroleum produced in Mexico. Besides petroleum, some food products and minerals are shipped from the port; imports include machinery, tools, motor vehicles and parts, metals, chemical products, and textiles.

Tampico is of modern construction, with stone and concrete buildings; it has several beautiful parks and plazas and large residential areas. The climate is usually mild, the maximum summer temperature seldom exceeding 95° F. and the yearly average being about 86° F. The rainfall averages about 40 in. annually. The city is visited regularly by ships from New Orleans and has daily air service to Mexico City, Brownsville, Tex., and other points. It is the terminus of two branches of Mexico's National Railways. While chiefly a commercial city, Tampico attracts sportsmen for its tarpon and sea bass fishing and its hunting.

Tampico existed before Cortes set out on his historic march from the shore at Veracruz in 1519. In 1523, Andrés de Olmos, a Franciscan friar studying Mexican dialects, reached the city and found it in ruins, but through his perseverance the Indians were attracted to the town, and it was gradually rebuilt. During the first twenty years of the twentieth century, exploitation of the oil fields brought a wildcat boom to Tampico, but the oil fever then subsided and the population diminished. Higher prevailing wages maintain a better standard of living in Tampico than in other sections of Mexico. Pop. 1950, 94,342. S. G. I.

**TAM-TAM.** *See* Tom-Tom.

**TANA** or **TSANA** [tɑ′nɑ, tsɑ′nɑ], a lake situated more than a mile above sea level and covering an area of about 1,400 sq. mi. in Begemdir and Gojjam provinces, northwestern Ethiopia. Lake Tana owes its origin to volcanic eruptions that dammed the upper reaches of the Blue Nile, or Abbai, as it is called in Ethiopia. Behind this natural dike, Lake Tana constitutes a vast reservoir for the headwaters of that river. The lake attains a depth of 45 ft. in places. Some of the many islands in the lake are volcanic, and on several of them there are churches, convents, and other religious buildings. The only town on the lake, Bahar Dar, with about 1,000 inhabitants, is situated on the southern shore. Gondar, with a population of 22,000, lies 30 mi. north of the lake.

The existence of Lake Tana was known in ancient times. It was rediscovered in the sixteenth century by the Portuguese, who called it Lake Dembea, and numerous explorers visited it and the Blue Nile during the nineteenth century. In the early twentieth century it was subjected to careful technical study by engineers and cartographers. The control of the headwaters of the Blue Nile, on which Egypt and the Anglo-Egyptian Sudan are dependent, has long been the subject of international negotiations and treaty-making. The British and Egyptian governments, in particular, have shown a marked interest in the various proposals that have been advanced for the construction of a dam at or near the outlet of Lake Tana. R. G. W.

**TANAGER** [tæ′nəjər], any of a large number of small (7 to 8 in.) New World songbirds constituting the family Thraupidae, most nearly allied to the finches. The great majority of them inhabit Central and South America, but a few forms migrate northward in summer to breed in the temperate regions of North America. As a group they are famous for their brilliant or even gaudy plumage, which sometimes combines as many as a half-dozen brilliant hues; some forms are, however, relatively plainly colored. Their bills are too soft to permit them, like the finches, to feed on seeds, and their diet consists, for the most part, of berries and insects. Four species of the genus *Piranga* reach the United States, where they are somewhat retiring dwellers in woodlands. Of these, the hepatic tanager, *P. flava hepatica,* is found only in the southwestern states; better known are the western tanager, *P. ludoviciana,* yellow and black with a red head; the all-red summer tanager, *P. rubra;* and the scarlet tanager, *P. olivacea,* which has an intensely scarlet body and black wings. H. G. De.

**TANAINA.** *See* Indian Tribes, North American (*Western and Eastern Subarctic*).

**TANAKA, BARON GI-ICHI** [tɑnɑkɑ] (1863-1929), Japanese statesman, was born in Yamaguchi in 1863. He graduated from military school in 1886 and rose rapidly in the Japanese army. From 1918 to 1921 he served as minister of war and directed the occupation of eastern Siberia. In 1927, when Japan was in a financial panic, Tanaka was named premier and minister of foreign affairs. He prevented the bankruptcy of the country's large corporations by declaring a bank holiday and by obtaining an important loan for the two major banks.

Tanaka is more widely known, however, for a paper he is believed to have written which outlines a planned imperialistic conquest of China, the Pacific, and finally the world. The Tanaka Memorial, discovered and published in China, was refuted by the Japanese government. Nevertheless, Japan followed the pattern of the Memorial in many subsequent actions. Tanaka himself was forced to resign as premier in 1929 because of repercussions over the death of Manchuria's dictator, Chang Tso-lin, who was believed to have been killed by Japanese troops sent to Manchuria by Tanaka to "protect" Japanese interests and treaty rights. Tanaka died in Tokyo, Sept. 29, 1929, shortly after his resignation. F. G. P.

**TANANA.** *See* Indian Tribes, North American (*Western and Eastern Subarctic*).

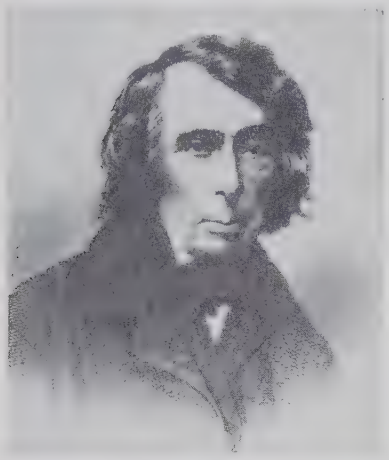
**TANANA RIVER** [tæ′nənə], 475 mi. long, one of the major tributaries of the Yukon River in Alaska. It rises in the glaciers of the Wrangell Mountains, in southeastern Alaska, and follows a winding course generally northwest, flowing into the Yukon at the town of Tanana. Fairbanks, the commercial and population center of interior Alaska, is located on a slough of the Tanana. The Tanana is frozen during the winter, but during the summer it is navigable by river boats for 225 mi. The river valley forms a natural transportation route which is utilized by the Alaska Highway. J. E. F.

**TANANARIVE** or **ANTANANARIVO** [tɑ′nɑ′nɑ′ri′v, ɑ′ntənæ′nəri′vo], the capital of Madagascar, a large overseas island territory of France off the east coast of Africa. The city is situated in the east central part of the island on a high plateau, 4,600 ft. above sea level, at 18° 46′ S. lat. and 47° 30′ E. long. It is about 135 mi. southwest of Tamatave, the principal seaport on the east coast, with which it is connected by railroad. The ancient capital of the Hova kingdom, Tananarive became, after the French conquest in 1895, the seat of the French administration of Madagascar and its dependencies. Pop. (est. 1949), 174,200; 1951, 177,059. W. S. V.

**TANCRED** [tæ′ŋkrɛd; tæ′ŋkrɪd] (c.1075-1112), renowned warrior of the First Crusade, was born in southern Italy about 1075, a grandson of the Norman adventurer Robert Guiscard. In 1096 Tancred set out with his uncle Bohemund I on the First Crusade, and the following year distinguished himself in battle at Nicaea and Dorylaeum. Tancred then advanced over the Taurus Mountains and secured Tarsus, but was driven out by Baldwin of Lorraine. Soon afterwards Tancred rejoined the main army and participated in the siege of Antioch. While Bohemund remained behind, Tancred led the advance guard to Jerusalem. He was conspicuous in the capture of the city and in the defeat of the sultan of Egypt's army before Ascalon, Aug. 12, 1099. He later returned to Antioch as regent for Bohemund, and, on the latter's death in 1111, succeeded to the principality. Tancred himself died a year later on Dec. 5, 1112. His deeds are celebrated in the literature of the Crusades. F. C. H.

**TANEY, ROGER BROOKE** [tɔ′ni] (1777-1864), American jurist, was born in Calvert Co., Md., on Mar. 17, 1777. He graduated from Dickinson College, Carlisle, Pa., in 1795, and studied law at Annapolis, Md., beginning a practice in 1799. That same year he successfully ran for election to the house of delegates as a Federalist. He was defeated for re-election in 1801 and 1803, and moved to Frederick, Md., to resume his legal practice. From 1815 to 1831 he was regarded as one of the outstanding lawyers of Maryland, where he served in the state senate and as attorney general, becoming a Democrat after the break-up of the Federalist Party. In

1831 President Jackson appointed him to the attorney generalship of the United States, and it was in this position that he became a trusted adviser to the president. Two years later he was appointed Secretary of the Treasury in place of William John Duane, who had refused to remove government securities from the Bank of the United States, then seeking a new charter. Taney felt that the bank was already too powerful and removed the securities, an action that was fiercely criticized by the Senate which subsequently refused to confirm his appointment. In 1835 Jackson nominated Taney as associate justice on the Supreme Court bench, but once again the Senate refused the confirmation. In 1836,



ROGER BROOKE TANEY

FROM AN ENGRAVING BY A. H. RITCHIE

COURTESY OF THE NEW YORK PUBLIC LIBRARY

however, the personnel of the Senate had changed and Taney was both nominated and confirmed to the post of Chief Justice of the Supreme Court, succeeding John Marshall, despite continued opposition to him as "Jackson's tool."

Taney is considered one of the really great justices, despite the fact that his decision in the Dred Scott Case helped the cause of slavery. His interpretation of the due process clause was a totally new concept in constitutional law, although the majority opinion in that case declared that slaves, as property, were not entitled to the rights of citizens and therefore could not bring a case before the Federal courts. Taney, himself, emancipated his own slaves. An outstanding jurist, he brought system to the court's procedure, a quality it had lacked under Marshall's leadership. Taney died in Washington, D.C., on Oct. 12, 1864. R. T.

**TANG.** *See* SURGEONFISH, DOCTORFISH, OR TANG.

**TANGANYIKA** [tæŋgənyi′kə; ta′nganyi′kə], a British trust territory in east central Africa, located just south of the equator, bordering the Indian Ocean. It is bounded on the north by the British dependencies of Kenya and Uganda, on the west by the Belgian trust territory of Ruanda Urundi and the Belgian Congo, and on the south by Northern Rhodesia, Nyasaland, and Mozambique. Off the coast are the islands of Pemba and Zanzibar, forming the British protectorate of Zanzibar. Lakes Victoria, Tanganyika, and Nyasa form a considerable part of the northern, western, and southern boundaries, respectively. The area of Tanganyika is 362,674 sq. mi., of which 19,982 sq. mi. are inland water. Prior to World War I, Tanganyika and Ruanda Urundi constituted German East Africa.

**Geographical Features.** *Topography.* Varying from 10 to 40 mi. in width, a low coastal plain extends for almost 500 mi. from the Umba River in the north to the Ruvuma in the south. Farther inland is a wider belt of rugged and rising terrain, beyond which is a great central plateau with an average altitude of almost 4,000 ft. It is the largest single land feature of Tanganyika. To the east and west of the plateau is an outward-facing escarpment, surmounted by broken ranges through which the rivers draining the plateau have cut in order to reach either the Indian Ocean or the western lakes. The biggest rivers breaking through to the east are the Pangani, Wami, Rufiji, and Ruvuma. The major river flowing west is the Malagarasi, which drains into Lake Tanganyika. Lake Victoria (3,720 ft. above sea level) is one of the headwaters of the Nile; Lake Tanganyika (2,534 ft. above sea level) empties westward into the Congo River system; and Lake Nyasa (1,568 ft. above sea level) empties into the Zambezi system. Lakes Tanganyika and Nyasa form part of the great African rift valley. Farther to the east is a secondary rift, neither so regular nor so deep as the great valley to the west, within which are Natron, Manyara, Eyasi, and Rukwa lakes. The northern extension of the rift across Kenya to Lake Rudolph is more clearly marked. Here and there throughout Tanganyika are isolated mountain massifs and broken ranges, mostly of volcanic origin. On the northern boundary is Africa's highest mountain, Kilimanjaro (19,565 ft.), flanked on the west by another volcano, Mount Meru (14,980 ft.), and on the southeast by the Usumbara Mountains. To the north of Lake Nyasa are several broken ranges, such as the Kipengere, which has altitudes of over 8,000 ft.

*Climate.* The rainy season extends from late November to early May. Toward the western lakes this season is divided into the early or long rains and the later or short rains, separated by an interval of relative dryness. Except on exposed mountain slopes, the western region has the highest precipitation, the annual average being above 70 in. The low coastal area has almost as much rain, averaging about 60 in. at Dar es Salaam. On the central plateau the average hardly reaches 30 in., though it is a little heavier in the rugged country between the plateau and the coastal plain. Deviation from the average tends to increase with altitude so that drought becomes a major agricultural hazard on the plateau.

*Flora.* Differences in temperature, largely owing to elevation, and variations in rainfall exert the strongest influence on the natural vegetation. Except near the western lakes and in the river valley flood plains, there is little dense tropical forest. The plant cover on the plateau ranges from savanna to park land. Predominant among the plants are the grasses, which are coarse along the coast but finer and more nutritious on the plateau. On much of the plateau, however, heavy drainage and other unfavorable circumstances sustain thorny, xerophilous shrubs over the grasses. The dominant trees on the coastal plain are the native mango and the imported coconut and mango. On the shoulders of the higher mountains the conifers become important, especially cedar and podo. Although not the most prevalent tree in the park land, the most useful is the mninga (*Pterocarpus angolensis*), which is highly valued in construction for its appearance and durability. The most valuable hardwoods, including mahogany, are found in the denser tropical forests near Lake Victoria and on the lower eastern slopes of the mountains.

*Fauna.* Several species of antelope, and also the lion, leopard, zebra, elephant, and giraffe, inhabit the open uplands. Monkeys are plentiful, but among the apes only the chimpanzee is found, and it only in the extreme northwest. Both the hippopotamus and crocodile live along the rivers. Among birds the most numerous are swimmers and waders. The ostrich has not quite disappeared from the uplands. Among

RUNE HASSNER FROM BLACK STAR

*Goat herders tending their flocks on the dusty upland plains of Tanganyika, in east central Africa*

poisonous snakes are the black mamba and puff adder. Much of the territory is infested with tsetse flies, mosquitoes, ticks, and locusts.

**Population.** Almost 99 per cent of the population is indigenous and basically Negro, with some Hamitic infiltrations in the north. Most of the Africans, especially in the interior, still retain their pagan beliefs and their ancient tribal practices. Some of the 120 tribes number only a few thousand each, others several hundred thousand. The largest is the Sukuma of the lake province, which has 51 chiefdoms and almost a million members. Other large tribes are the Nyamwezi, Gogo, and Chagga. The pastoral Masai on the Kenya border are predominantly Hamitic in speech and race. Most of the tribes speak variants of Bantu, but the dialects are so distinct that intertribal communication is usually difficult and often impossible. Swahili, a mongrel tongue composed principally of Arabic and Bantu, is the lingua franca throughout the territory, exclusively used along most of the coast and by many in the inland trading centers.

Tanganyika's population was estimated at 8,069,300 in 1953. This included 7,965,000 Africans, 20,300 Europeans, and 84,000 other non-Africans, mainly Asians. The African population has rapidly increased, having risen from 5,545,450 in 1945. The principal cities, with their populations at the 1952 census, are: Dar es Salaam, 99,140; Tanga, 22,136; Tabora, 14,011; and Mwanza, 13,691.

**Government.** *Administration.* At the head of the administration is a governor appointed by and responsible to the British Colonial Office. He is assisted by an executive and a legislative council. Acting under a United Nations trusteeship agreement, the British administration is also responsible to the U.N., submitting annual reports to the international body and opening the territory to periodic visits by U.N. inspection missions. A new constitution put into effect in 1955 provided for an enlarged legislative council of 61 members, including 31 official government members and 30 unofficial nominated members. The unofficial membership was divided equally among the territory's three cultural groups—10 Europeans, 10 Asians, and 10 Africans—in a new "parity" formula put into practice for the first time in the British East African possessions. For local administration Tanganyika is divided into 8 provinces, then subdivided into districts. Provincial and district commissioners supervise local government. In 1949 the first provincial council was established for the Lake province, and one for the Southern Highlands province in 1950. Officially authorized native authorities are being increasingly used in both administrative and judicial functions. The largest of these is the Sukumaland federation established in 1946. It is the policy of the government to encourage chiefdoms to assume responsibility and thus promote self-government on a local level without destroying tribal cohesion and mores. In 1949 Dar es Salaam was granted municipal status and a considerable measure of self-control.

*Currency and Public Finance.* The only legal tender in Tanganyika is the East African shilling, which remains at par with the British shilling. Prior to September 1949 it had a value in United States currency of 20 cents; since then 14 cents. The total revenue for the fiscal year 1953 was £14,727,895; expenditures were £14,724,489.

**Economic Activities.** *Agriculture.* In 1953 there were an estimated 14,000,000 acres, out of a total of almost 220,000,000 acres, under cultivation. The crops, most of which are tilled for local consumption, include maize, millet, sorghum, cassava, and sweet potatoes. The leading export crops are sisal, pyrethrum, cotton, copra, tea, rice, peanuts, bananas, and coffee.

*Livestock.* The area of actual pasture land is officially estimated at about 43,000,000 acres. The chief animals raised are cattle (6,605,300 head in 1953), goats (3,670,400), sheep (2,783,400), and donkeys. Cattle, the major breeds of which are the zebu and Ankoli, are regarded as the primary form of wealth among the indigenous population. European breeds, principally for dairy products, are raised by non-Africans. There is some interbreeding with native cattle.

*Mining.* The most important mineral products are diamonds and gold. The Shinyanga district of Lake province is the principal diamond center, where valuable discoveries were

C. TRIESCHMANN FROM BLACK STAR

*A clock tower of simple design occupies the center of the public square at Arusha, in northeastern Tanganyika.*

made in 1940. The territory's allocation of diamond production is one tenth of world production, and in 1953 amounted to 170,679 carats worth £2,100,000. Gold, which in 1953 totaled 69,886 troy oz. of refined bullion valued at £903,993, is widely distributed, but the main center is in the southern Chunya district in Southern Highlands. Other minerals include sheet mica, tin, and salt. Still in the development stage are coal, iron, kaolin, tungsten, lead, and silver. Considerable amounts of lime and building stone are produced for local use. Surveys of promising coal and iron deposits on either side of the Ruhuhu Valley near Lake Nyasa are being actively conducted, and the exploitation of lead deposits at Mpanda, in the west, will be greatly aided by the railway recently constructed into that area.

*Transportation.* The railways, now under the East African Railways and Harbours Administration, are all of meter gauge and totaled about 1,500 mi. in 1950. More than 16,000 mi. of roads, chiefly suitable for light traffic during the dry season, are maintained by the central or provincial governments. The Great North Road, which links the Union of South Africa with Egypt, passes through the territory. The East African Railways maintains steamer service on Lakes Victoria and Tanganyika, and the Nyasaland Railways on Lake Nyasa. The East African Airways connects the main centers of Tanganyika with those of Uganda, Kenya, Nyasaland, and Zanzibar. At Dar es Salaam and Nairobi, capital of Kenya, connections are also made with British Overseas Airways and other intercontinental services.

*External Trade.* The total value of domestic exports in 1953 was £34,545,000. Less than half was accounted for by the export of sisal hemp and tow valued at £12,773,000. Other items of domestic export are coffee, raw cotton, diamonds, gold, sheep and goat skins, crude papain (papaw extract), pulse, timber and lumber, rice and other grains, leopard skins, beeswax, peanuts, fish, and tobacco. Total value of imports for domestic consumption was £28,427,000; of the total, textiles and clothing accounted for £4,703,000. Imported vehicles and their parts, including railway rolling stock, ships, and aircraft, were valued at £7,468,000. Other imports are electrical goods and machinery, galvanized sheets and other iron and steel manufactures, cigarettes, petroleum products, oils and fats, tools and instruments, cement, and tires and tubes.

**Social and Cultural Activities.** *Education.* The primitive character of much of the life in Tanganyika has resulted in, as well as contributed toward, the backwardness of its educational institutions. Arab Koranic schools made almost as little impression on the life of the country as those of the Portuguese Jesuits. The German government was content to leave education to the missionaries and actively opposed Islamic instruction. The British government was at first disposed only to supply the mission schools with some supervision and small grants in aid, but by 1953 the educational budget had grown to £3,198,690, five times the 1948 figure. Besides primary and secondary schools there are industrial and vocational schools. Enrollment in all schools is small. Higher educational facilities do not exist in Tanganyika, but are available in Uganda and Kenya. Students attending these institutions, as well as those registered in British universities, receive government assistance.

In the curriculum of African primary schools in Tanganyika, Swahili is the medium of instruction. Teaching of English is begun in the fifth year and becomes the language of instruction in secondary schools. In Asian schools, Gujarati or Urdu is used in the primary and English in the secondary grades. European primary schools must teach English, but it need not be the language of instruction. There are no European secondary schools.

**History.** The coast of Tanganyika has been known to the outside world for more than twenty centuries, the interior for hardly more than one. The Greeks knew the coast well, but their maritime enterprise was gradually smothered by Roman land imperialism in which East Africa had no place. Eventually the Arabs became heir to the Greeks, and following the rise of Islam they not only gained a dominance along the coast but established trading colonies. In the tenth century they were supplanted by the Persians, but when the Portuguese explorer Vasco da Gama reached the coast in 1498 the Arabs had for centuries again been in control. Sporadically attacked by Turks, Arabs, English, and Dutch, the Portuguese hold on this part of the African coast had begun to weaken by the end of the sixteenth century, and by the end of the seventeenth the Arabs were back in force. The economic foundation of their East African empire remained the slave trade until the collapse of their power in the second half of the nineteenth century. Ujiji, on Lake Tanganyika, and Tabora, on the plateau, were important inland stations; Kilwa, Lindi, Dar es Salaam, and Pangani were major coastal settlements. The sultan of Muscat claimed overlordship throughout, but local Arab sheiks often paid only slight heed to his commands. In 1832 Said, Sultan of Muscat, transferred his headquarters to Zanzibar, and in 1856 Zanzibar became a separate sultanate. In the same year two British explorers, Sir Richard Francis Burton and John Hanning Speke, entered the territory, and were soon followed by Livingstone and Stanley. The separation of Zanzibar (to which the coastal area was attached) from Muscat caused an intensification of the slave trade just as the first missionaries were attempting permanent establishments. Missionary appeals to the conscience of the Western world served to bring East Africa vividly to public attention.

In 1884 a German promoter, Karl Peters, concluded several treaties with inland chiefs and in the following year was successful in securing a German protectorate over the country, which received the name of German East Africa. Spo-

radic native uprisings followed, the last and most serious being in the south in 1905. The German government came to regard this colony as its most promising dependency, but economic development proved expensive and Germany undoubtedly expended more than it earned in promotion of the colony. Just before the outbreak of World War I the German Central Railway was completed across the country from Dar es Salaam to Kigoma on Lake Tanganyika, and the Tanga line near the Kenyan border was opened. So well trained and equipped was Germany's native African army that, despite the blockade of the coast, General von Lettow-Vorbeck was able to keep the field until after the signing of the armistice. All of German East Africa, except the districts of Ruanda and Urundi, was mandated to Great Britain following the war, and the mandatory system was formally inaugurated in 1922 under the name Tanganyika.

In 1923 the customs schedules of Tanganyika, Uganda, and Kenya were assimilated, and the three customs establishments were amalgamated in 1949. A legislative council was set up in 1926 with 13 official and not more than 10 unofficial members. In 1945 the ratio of official to unofficial was changed in favor of the latter to 15 official and 14 unofficial members, of whom 4 by 1948 were native Africans. In 1926 the annual governors' conference, including Tanganyika, Uganda, and Kenya, was formally established, and in 1948 the interterritorial organization was inaugurated. The transportation services of the three territories were fully amalgamated in 1948. In 1946 Tanganyika became a trust territory for whose administration Great Britain is responsible to the United Nations. Although Tanganyika's population is more primitive and politically undeveloped than either the Kikuyu tribe of Kenya or the Baganda of Uganda, the trusteeship system has led to increased pressure for greater self-government in the territory. After touring Tanganyika in 1954, a U.N. visiting mission proposed the setting of a target date for autonomy. Britain opposed the concept of a timetable, but pledged itself to continued leadership toward self-government. *See also* BRITISH EAST AFRICA. W. M. W.

**TANGANYIKA,** a lake in eastern central Africa, the longest fresh water lake in the world. It is 450 mi. long, 30 to 45 mi. wide, and has an area of 12,700 sq. mi. With a depth of 4,708 ft. and its floor dropping to 2,172 ft. below sea level, it is also the deepest fresh water lake in the world after Lake Baykal in Siberia. Lake Tanganyika lies between the Belgian Congo, Tanganyika, and Northern Rhodesia. The Russisi River enters it at the north, and the Malagarasi is the largest of many feeder streams. The water level often changes because of rainfall fluctuations. Surrounding forest vegetation is luxuriant, and the fertile soil produces rice, maize, manioc, sweet potatoes, and sugar cane. Bantu tribes dwell around the lake, which was circumnavigated by Stanley in 1876. Chief towns are Ujiji and Usumbura.
S. Van. V.

**TANGELO** [ta′njəlo], a group of hybrids made between the mandarin orange, *Citrus reticulata,* and the grapefruit, *C. paradisi,* or the closely similar pummelo (or shaddock), *C. grandis.* The resulting fruits more closely resemble the orange and are rich in color and flavor, excellent for juice and marmalade, but too delicate to be shipped satisfactorily.
C. H. Wo.

**TANGERINE,** a small reddish-yellow citrus fruit, *Citrus reticulata* or *C. nobilis deliciosa.* It is smaller than the orange, oblate in form; it has an easily separable rind and a sweet pulp. The tangerine, known as the kid-glove orange, is produced in the Orient and in the United States. C. R. Eb.

ROSS MADDEN FROM BLACK STAR

*A well-traveled stone staircase descends to the shopping district in Tangier, internationalized seaport in northwestern Morocco.*

**TANGIER** [tanji′r], an international zone including the seaport city of the same name, situated in Morocco in the extreme northwestern corner of Africa. The zone is bordered by the Atlantic Ocean, at the western end of the Strait of Gibraltar, and is surrounded by Spanish Morocco on the landward side. It has an area of 147 sq. mi. and in 1953 had a population of 157,000. The city of Tangier had a 1953 population of 90,000.

Rising in tiers from the Bay of Tangier, the city, which is about 220 mi. northeast of Casablanca, culminates in two hills. It was formerly a walled town, and some sections of the ramparts still exist, but surrounding the old Moorish nucleus are several new European quarters which have been built in conformity with the prevailing Mediterranean style. Seen from the sea, Tangier presents a white and gleaming aspect. After World War II it became a haven for refugees from various parts of Europe, as well as for business enterprises seeking to take advantage of the favorable laws of Tangier.

The harbor has been improved by dredging and breakwaters, but it still accommodates only small ships. Since the establishment of the French protectorate in Morocco, Casablanca has absorbed much of the trade that Tangier had hoped to acquire, a situation altered only slightly by the completion of the Tangier-Fez Railway in 1928. Tangier is a trading and fishing center of local importance, and certain small factories are in operation. In addition to the railway, Tangier is connected by good highways with the French and Spanish zones.

**History and Government.** The ancient Roman city of Tingis was located near present-day Tangier. It fell successively under Vandal, Byzantine, and finally Arab rule at the end of the seventh century. It remained under Arab control until, after several abortive attempts, Portugal captured it in 1471. The area was subject to Spain from 1580 until 1656. Returned to Portugal, it was ceded six years later to England as part of the dowry of the King of Portugal's sister, Catherine of Braganza, who married Charles II of England. In 1684, however, the English decided that they no longer wanted to have the expense of defending Tangier against the

Sultan of Morocco, and allowed the Moors to take possession of the city.

When the Moroccan situation became a matter of general concern and action at the beginning of the twentieth century, the status of Tangier presented a particularly knotty problem because of its strategic location. In the Moroccan agreements of 1904, involving Great Britain, France, and Spain, a separate settlement for Tangier was anticipated. France and Spain determined the boundaries for the Tangier Zone in 1912, but the convention setting up the regime for this territory, negotiated by Great Britain, France, and Spain in 1914, was never put in force because of the failure on Spain's part to sign it. Negotiations were resumed in 1923, and on December 18 Great Britain and France signed an agreement creating for Tangier a new regime to which Spain adhered in February 1924. The statute was formally put into operation in June 1925, and modifications were introduced at the Tangier Convention of 1928. Among other provisions, Italy was accorded participation in the international administration, and Spain was given a larger share. None of these arrangements, however, could revive the city's economic life.

FPG

*A native of Tangier, hooded against the strength of the afternoon sun, bargaining for a roll of colorfully patterned matting in the open-air market of Zoco Grande*

In June 1940 Spanish Khalifan troops invaded the Tangier Zone, ousted most of the international agencies governing it, and placed the territory under the rule of the Spanish High Commissioner for Morocco. Later, steps were taken to achieve virtual annexation of the Tangier Zone to Spanish Morocco.

With the end of World War II in Europe, a conference of French, British, United States, and Russian representatives, meeting at Paris in 1945, agreed on the establishment of a regime in Tangier based on the 1923 convention, and on Oct. 11, 1945, international rule was restored. The Tangier Zone is demilitarized. *See also* Morocco.

**TANGO** [tæ′ŋgo], a leisurely, measured ballroom dance in duple meter executed by couples and characterized by the rhythm ♩.♪ ♩♪, against which the melody is often syncopated. The tango first appeared about 1900 among dock hands and other slum dwellers in Buenos Aires and elsewhere around the mouth of the La Plata River. Most of these people were migrant West Indian and Central American Negroes, and it seems evident that the tango developed out of earlier and very similar West Indian dances, such as the habanera and the tangano, from the latter of which the tango may have inherited its name. By about 1910 the tango was a favorite in Argentine ballrooms, and within a decade it had become popular in Europe and, to a lesser degree, in North America, although not without opposition from churchmen and purists, who objected to its suggestive movements. Among Europeans the melancholy music and unhurried elegance of the tango, although they have now become somewhat refined and stylized, have made it a leading ballroom dance, but in North America it has never lost its exotic flavor and remains largely an exhibition dance. During the 1920's especially, European composers were fond of introducing stylized tangos into art music.

The Spanish tango, a fiery solo dance of the flamenco type, belonging rather to the Spanish gypsies than to true Spaniards, seems to have nothing in common with the Argentine tango described above save the coincidence of name. P. N.

**TANGUT.** *See* Asiatic Tribes (*Sinitic*).

**TANJORE** [tanjo′r], the chief city in a district of the same name in southeastern India. The city is located in southeastern Madras State on the southernmost distributary of the Cauvery River at 10° 47′ N. lat. and 79° 10′ E. long. It is near the western edge of a fertile plain in the Cauvery Delta, about 60 mi. west of Negapatam, a port on the Bay of Bengal. The city receives from 30 to 50 in. of rain annually, most of which falls during the winter, December having from 5 to 10 in. High temperatures prevail throughout the year. The dry summer, and fluctuation in the amount of winter rain, made agriculture precarious and famine common until the Mettur Dam was built on the upper Cauvery River to provide irrigation by way of more than 3,500 mi. of canals and ditches in the area. Rice is the major crop and some millet, sesame, tobacco, and sugar cane are grown. In addition to being an administrative, agricultural, and railroad center, Tanjore is known for its manufacture of jewelry, carpets, and metal ware. A Dravidian temple, built in a pyramidal form with many carvings and sculptures and enclosed by an old fort, attracts visitors as does an old palace, also within the fort. The city was the administrative center of the Chola Kingdom during the eleventh century, was captured by the Marathas in 1674 and then by the French, who relinquished it to the British in 1855. Tanjore remained part of British India until 1947, when it became a part of the dominion of India. Pop. 1951, 100,680. J. E. F.

**TANKS.** Tanks are armored motor vehicles mounting armament and intended primarily for offensive combat. The tank is a self-propelled vehicle of the track-laying type, with its main armament usually mounted in a turret with full traverse, and with armor designed to give over-all protection for crew, armament, and power plant against enemy fire.

Tanks are classed according to their use and weight as light, medium, and heavy tanks. In the light tank, intended for reconnaissance and for operation against enemy troops, mobility is emphasized. The designation "light" is relative, and the light tank in production for the United States Army at the end of World War II was as heavy as the medium tank of 1939 and mounted a heavier gun. The medium tank is a vehicle designed to combine mobility and firepower. It carries firepower to cope with enemy tanks and centers of resistance, armor to afford protection against medium caliber fire, and has mobility to exploit thoroughly

penetration of the enemy's line of resistance. In the heavy tank the major emphasis is upon firepower and protection, with mobility a secondary consideration. It is an assault vehicle, designed to absorb and deflect enemy fire.

The policy of the United States following World War II called for a light tank to be used by armored regiments (light) and by divisional reconnaissance squadrons; a very light tank, air transportable, for airborne troops; a medium tank for the tank battalions of infantry and armored divisions, and for the tank companies of infantry regiments; and various types of special tanks, as described below. The development of a new heavy tank was delayed in hope that new anti-tank weapons would make heavy tanks obsolete.

**U. S. Army Tanks.** At the end of World War II, the standard United States Army light tank was the M24, a vehicle weighing about 20 tons, carrying, as main armament, the 75-mm. gun, turret mounted, powered by two V-8, liquid-cooled engines, with torsion bar suspension, and armor of 1 in. thickness. Also standard was Light Tank, M22, an airborne tank weighing about eight tons with a 37-mm. gun as main armament. In World War II light tanks carried crews of four men and had a cross-country speed of about 25 m.p.h. Their chief use was as speedy reconnaissance vehicles in the North African, European, and Pacific campaigns. In 1952 the new "Walker Bulldog" light tank, M-41, was coming into service; it weighs 26 tons and carries a 76-mm. gun.

In World War II, the Medium Tank, M3, was developed. It was a vehicle weighing about 31 tons, with main armament of a 75-mm. gun, sponson mounted with limited traverse. Auxiliary armament was a 37-mm. gun, turret mounted, and .30 caliber machine guns, with a maximum armor thickness of 2 in. upper front hull and 2¼ in. on the turret. The vehicle was powered by a 9-cylinder, air-cooled radial engine. Turret and sponson were cast, and the hull was of riveted construction. Because of its superior firepower the M3, while an expedient pending development of a tank carrying main armament turret mounted, was highly successful in the North African theatre. The M3 was succeeded by the Medium Tank, M4, the Sherman tank. This vehicle used the chassis of the M3, with power plant and power train, weighed about 31 tons, had as main armament the 75-mm. gun, turret mounted, and had a maximum armor thickness of two inches on frontal hull surfaces and of three inches on the turret front. The M4 series of medium tanks was the backbone and principal combat vehicle of the Armored Force. In World War II they were used in assault as supporting artillery for troops.

The Pershing (M-26) 45-ton tank carrying a 90-mm. gun came into limited use late in the war, and afterward was for a time the standard United States medium tank. In Korea, however, the M-26 proved to be underpowered for operations on difficult terrain. The Patton medium tanks—M-46, M-47, and M-48—became, after 1950, the backbone of the United States armored forces. The latest of these, the M-48, weighs between 45 and 50 tons, is armed with a 90-mm. gun and 3 machine guns, has an 810-hp. V-12 air-cooled engine and a cross-drive transmission, and carries a crew of four men. A heavy tank (T-23), armed with a 120-mm. gun but weighing very little more than the Patton, was under test in 1952.

Special-purpose tanks include the following types: (a) the flail tank, equipped with mechanical devices for beating the ground in front of the tank for the purpose of exploding land mines in the tank's path, and also for smashing barbed wire entanglements; (b) the flame-thrower tank, for reaching enemy personnel in caves and other deep shelters; (c) the fascine tank, equipped to carry bundles of brushwood to fill up anti-tank ditches; usually used in connection with an armored bull-dozer, which shovels earth on top of the fascines to make a causeway across the ditch; (d) the bobbin tank, which carries a huge reel of reinforced coir matting which unrolls underneath the tank and thus makes a path over soft ground on which other tanks and vehicles can follow; (e) the ramp tank, called the Ark by the British, which has ramps fore and aft by which ditches or sea-walls may be crossed; (f) the bridge tank, carrying a long bridge-section capable of spanning a small stream; and (g) amphibious tanks with propellers as well as tracks, for use in connection with landing operations.

*The M4 Sherman tank, developed in World War II as a standard unit of infantry attack*

**Armored Artillery.** During World War II, the United States Army developed various types of self-propelled guns, both for attacking hostile armor and supporting its own. These were often called "tank destroyers." Since the war, standardized types of self-propelled armored artillery have been developed for assignment to armored divisions.

**British Tanks.** The British Army has pioneered in tank design. During the later phases of World War II, however, the Royal Armoured Corps used tanks mainly of American manufacture. One notable British tank was the "Churchill," a large tank carrying a turret-mounted 6-pounder gun and 2 machine guns, used chiefly for close support of infantry. The postwar British medium tank is the "Centurion," a 50-ton tank with a 635-hp. Rolls Royce engine, mounting an 85-mm. gun. This tank has operated with notable success in Korea with the British Commonwealth Division and, in 1952, formed the basic armament of the three British armored divisions stationed in Germany.

**Russian Tanks.** The best-known modern Soviet tanks are the medium T-34, weighing 37 tons, very heavily armored (especially in front), and carrying either a 76-mm. or an 85-mm. high velocity gun, and the heavy "Josef Stalin" tank, a 50-tonner armed with a 122-mm. gun. Earlier models of the Stalin tank weighed as much as 57 tons. H. W. E.

**TANNA** [tɑ′nɑ] (pl. tannaim), an Aramaic term meaning "teacher" and designating the early Talmudic sages who flourished in Palestine in the first two centuries of the Christian Era. Traditionally, they were the successors of the sopherim (scribes) in transmitting the Oral Law to posterity. The teachings of the tannaim are found primarily in the Mishnah, a compilation of laws constituting part of the Talmud; but they are also found in the midrashim (rabbinical exegetical works) and in the tosephta and the baraithas (bodies

of legal material, Mishnaic in character, but excluded from the Mishnah). The tannaim, of whom more than 200 are known by name, are divided into six consecutive groups, or generations, who flourished in the following approximate periods: A.D. 10-80, 80-120, 120-140, 140-165, 165-200, and 200-220. They were addressed by the title rabbi, or some, by reason of their distinction, by the even more respectful title rabban. Not all tannaitic quotations bear the names of their authors, but in many cases authorship may be established by comparison with a text of known authorship. *See also* MISHNAH; TALMUD. M. A. G.

**TANNENBERG, BATTLES OF** [tɑ′nənbɛrχ], two famous battles, five hundred years apart, both of which had important results. The first, sometimes called Grünwald, was fought July 15, 1410, between a Polish army allied with a smaller force of Lithuanians, and commanded by King Ladislas II of Poland, and the Order of the Teutonic Knights. It resulted in a crushing defeat for the Knights and marked a definite beginning of the end of their expansion and power. The Order never recovered from the defeat. The second battle, one of the early and decisive engagements of World War I, was fought on the eastern front between German and Russian troops, Aug. 26-29, 1914. The defeat of the Russians was so disastrous that any further threat to East Prussia was temporarily removed. The Battle of Tannenberg ended any imminent danger of Russian invasion of Germany. It nullified the Russian gains in Galicia and enabled Germany to turn once more to the western front. M. K.

**TANNHÄUSER** [tɑ′nhɔizər], an opera in three acts by Richard Wagner, who based his libretto on medieval Germanic legends. It was first performed on Oct. 19, 1845, in Dresden and was revised to its present form for a production in Paris in 1861. In this work Wagner began to extend his use of musical motives to underline or comment upon the action, and for the first time he adopted the vocal style which he called *sprechgesang,* or speech-song, a highly dramatic free declamation which breaks now and then into lyric melody. In this style the distinction between aria and recitative has been broken down and only the long line of purely expressive speech-melody is heard. Wagner also began, in this opera, to assign a more important role to the orchestra, the expressiveness of which was enormously extended by the increased number of instruments he demanded. Musicians, even the performing artists, were puzzled or repelled by the new style, but a few adherents, who were for the most part not musicians, were so strongly drawn to Wagner's ideas that it is possible at this time to perceive the beginnings of what later became the Wagner cult.

The story of the opera is set in thirteenth-century Thuringia and borrows the name of the historical Tannhäuser, who was a minnesinger. The Tannhäuser of the opera (tenor) is a medieval knight who has found his way to the Venusberg, where he now lives with Venus (soprano). He becomes weary of sensual love, however, and returns to his friends in the world of men. When he tells of his experiences, he is regarded with horror and is urged to join a group of pilgrims and seek absolution at Rome for the sin of profane love. This is at first refused him, but the unselfish devotion of the Lady Elizabeth (soprano) finally obtains him forgiveness. S. C.

**TANNING.** *See* LEATHER.

**TANNINS** [tæ′nɪnz], a large class of substances found in plants and in barks of certain trees. They precipitate gelatin solutions, tan hides, and form bluish-black color combinations when in contact with ferric salt solutions. For tanning purposes water extracts of gall nuts and of such barks as oak, wattle, and hemlock are employed. The color produced upon the addition of solutions of iron salts has made the tannins useful in the manufacture of certain inks and bluings. The chemistry of the tannins is known to a considerable degree. They are all derivatives of aromatic acids and contain polyhydric phenol structures. Some of the simpler tannins have been synthesized in the laboratory. *See also* LEATHER. E. H. Co.

**TANNU TUVA.** *See* TUVA AUTONOMOUS OBLAST (REGION).

**TAN OAK,** a tree, *Lithocarpus densiflora,* of California and southern Oregon, sometimes 150 ft. high, closely related to the oak. All of the other 100 species of *Lithocarpus* are confined to southeastern Asia. W. D. B.

**TANSY** [tɑ′nzi], strong-scented herbs, *Tanacetum,* of the family Compositae, distributed throughout the Northern Hemisphere and comprising 35 species, of which 7 are native to North America. They bear alternate leaves and heads of

THOMÉ - DR. LASCOFF

*The common tansy,* Tanacetum vulgare, *showing detail of root, seed, flower and leaf*

small to medium-sized yellow flowers. The common tansy, *T. vulgare,* native in Europe, is grown extensively throughout North America in old gardens, from which it has escaped to roadsides and waste places. It is a perennial about 3 ft. high, bearing deeply cut aromatic leaves and dense clusters of small yellow flower-heads in midsummer. It was formerly widely in use in a dried form for seasoning and medicinal purposes, and is still sometimes employed as a household remedy for rheumatism and bruises. E. R. C.

**TANTA** [tɒ′ntɒ], a city in northern Egypt, situated in the center of the Nile Delta, about 60 mi. northwest of Cairo. It is the capital of the province of Gharbiya. As the chief railway center in the Delta, it is connected with Alexandria,

Cairo, Mansura, and Damietta. Tanta is famous for the mosque containing the tomb of Ahmed al-Bedawi (c. 1200-1276), Egypt's greatest Moslem saint. There is a branch of Cairo's al-Azhar University here. Pop. 1947, 139,926.

W. S. V.

**TANTALUM** [ta′ntələm], symbol Ta, atomic number 73, at. wt. 180.88, density 16.6, m.p, 2,996° C., b.p. over 4,100° C. Tantalum (its name a Latin derivative from the Tantalus of Greek mythology) is a transition metal in Group V-A in the periodic table, closely related to columbium, and less closely to vanadium. The principal source of tantalum is iron tantalate, $Fe(TaO_3)_2$, frequently associated with columbite. Tantalum is a white metal, remarkably ductile, malleable, strong, and tough. It resists the action of acids, including aqua regia, but is dissolved by a mixture of nitric acid and hydrofluoric acids. With fused alkalies it forms tantalates, such as $K_8Ta_6O_{19}$, soluble in water and hydrolyzed by boiling. Tantalum metal is used to make dental and surgical instruments, corrosion resistant equipment of many sorts, electrodes, rectifiers, pens, and standard weights. It is almost indispensable in constructive surgery. B. S. H.

**TANTALUS** [ta′ntələs], in Greek mythology, a king of Sipylus in Lydia (or of Phrygia), the son of Zeus and father of Pelops. He was admitted to Olympus by Zeus but abused the friendship of the gods. His crime is variously reported: (1) he attempted to deceive the gods by serving them at a banquet the flesh of his son Pelops; (2) he stole their nectar and ambrosia; (3) he divulged the secrets of the gods; or (4) he denied knowledge of a golden dog stolen from the shrine of Zeus. His punishment in Tartarus was proverbial and has given rise to the English verb "tantalize." Parched with thirst, he stood in a pool with water to his chin, but the water always receded as he tried to drink; over his head were fruits which the winds moved away as he tried to grasp them. *See also* Pelops. G. E. D.

**TANTU.** *See* Chinkiang.

**TAOISM** [dau′izəm], two radically different Chinese movements—on the one hand, a philosophy, on the other, a positive religion. Philosophic Taoism has exalted mysticism, naturalness, and simplicity, the securing of solace in misfortune by the cultivation of inward calm, *laissez faire,* optimism, and skepticism of doctrinaire programs.

Religious Taoism probably developed out of much older elements during the fifth and subsequent centuries of the Christian Era, and it was encouraged as a native religion in order to compete with foreign Buddhism. The founder of Taoism is traditionally considered to have been Jang Ling (or Chang Tao-ling) of the second century of the Christian Era. The present chief Taoist priest and magician claims descent from him and calls himself by his ancestor's title, the *Tien-shzh* ("Heaven's Apostle"). Early accounts of Jang Ling's teachings indicate, however, that he taught the Persian Mazdaism of the Later Avesta. He cured diseases by having his patients confess their sins and pray to three high gods: Heaven (probably Mithra), Earth, and Water (probably Anahita). The Mazdean supreme God, Ahura Mazda, was in Persia called *"Dadhvah,"* the "Creator," which was translated by the Chinese word *"Tao."* Members of this Chinese cult worshiped *Tao* as a personal God. Zoroaster's name for the highest heaven, *"Garo-dman,"* became the Chinese *"Ta-lo."* The location of Jang Ling's fire temple on a hill north of the present Chengtu, Szechwan, is still shown; he organized a hierarchy of priests and emphasized the position of angels and of purity, both prominent in Mazdaism. Chinese bronze mirrors of the first four centuries of the Christian Era, which are commonly said to represent "Taoistic divinities and dragons," are probably charms of this cult. It spread to the imperial court and thence to the Yangtze delta, where it became important, securing the allegiance of prominent ministers and officials. A rebellion led by Taoists in 399-410 resulted in its drastic suppression.

"Gentlemen of the *Tao* (*Tao-shzh*)," such as Kou Chien-jzh, took over the cult's remnants in 415 and united them with other Chinese and Buddhistic elements to produce religious Taoism. Among these elements was alchemy, which probably originated with Dzou Yen, and which promised the prolongation of life through the elixir of immortality, made from alchemical gold. Dietary practices were also added, especially the avoidance of grain and the eating of magical mushrooms and minerals. Prolonged meditation and control of the breath were cultivated, as was communication with immortals (*sien*) and other supernatural beings. This cult had attached itself to the Lao-tse, but not to Juang-tse. During the second millennium of the Christian Era, physical alchemy became an esoteric spiritual alchemy, using such terms as sulphur, mercury, and gold to denote special bending and stretching exercises, massage, mental self-control, cultivation of calmness, acceptance of the inevitable, and the mystical ecstasy.

Contact with Buddhism added other details to Taoism, of which the most important were monasteries and temples. Ancient hermits and immortals became gods, and were worshiped for their favors. Planets, stars, ancient heroes, human activities, even robbery, fornication, and drunkenness, beasts and insects, such as grasshoppers, snakes, tigers, and dragons, were honored as minor divinities. The "Three Stars" of Happiness, of Emolument, and of Longevity, together with the "Eight Immortals" are mostly literary and symbolic figures, for they are rarely worshiped. Ancient Chinese gods were added to the Taoistic pantheon, such as the God of the Eastern Sacred Mountain (Mount Tai), who acts as the divine ruler of China; Guan Yü, an ancient hero who became god of war; and the Mother Queen of the West (*Si-wang-mu*), who rules the terrestial heaven on the Kun-lun Mountains and raises the peaches of immortality. Jang Ling's triad of Heaven, Earth, and Water was continued. And at the head of this pantheon was placed the Jade Emperor (*Yü-huang Shang-di*), a god first mentioned in the ninth century. Since Jade denotes purity, the Jade Emperor was probably a new designation for Jang Ling's God, Tao.

An important Taoistic doctrine is that good and evil deeds are duly repaid. The *Book on Responses* ("rewards & punishments") *Evoked by Good and Evil Deeds* (*Gan-ying-pien*) is perhaps the most popular Taoist tract. According to this work, the kitchen God (*Dzao-shen*) and guardian spirits watch individuals and report their deeds to the Jade Emperor or other gods; and the god of the Northern Bushel (the Dipper) records people's deeds and lengthens or shortens their lives accordingly. The fear of hell is inculcated by life-sized, brilliantly painted figures in temples. The supreme triad consists of the recluse Lao-tzu, who has gone into retirement, the Jade Emperor, who now rules, and the future Savior.

Taoist practitioners today make their living chiefly by calling upon members of the divine hierarchy to defeat the machinations of the devils who cause diseases and calamities. They name the devil that has occasioned any trouble, and they know to which god to appeal for relief. Contemporary Taoism is a thoroughly superstitious and loosely organized

*Ruins of the Greek Theatre on the promontory of Taormina, in northeastern Sicily, overlooking the Ionian Sea. Of Greek origin, the theatre in its present form dates from a Roman restoration of the second century A.D.*

system. Long decadent, it has lost the respect of intelligent Chinese. H. H. D.

**TAORMINA** [tɑ′ɔrmi′nɑ], a famous and historic resort town on the east coast of Sicily, midway between Messina and Catania. Situated on the side of the coastal range at an elevation of 650 ft., Taormina enjoys an incomparable view of the sea and of Mt. Etna. The combination of scenic beauty and mild climate has made of Taormina and its environs a well-known winter resort. There are numerous hotels as well as many private villas. Taormina was founded by Greek colonists at the end of the fifth century B.C. and shared the political history of the near-by Greek cities before and during Roman occupation. Its importance outlasted the Empire, but in 902 it was destroyed by the Arabs, who later rebuilt it. The city prospered under Norman rule but declined later. Among the monuments worthy of mention is the Greek theatre, constructed during the Hellenistic Period and second in size only to that at Siracusa among Greek theatres in Sicily. Taormina is the center for many excursions to beautiful and interesting sites, such as the Castle of Taormina and the Grottoes of Capo Sant' Andrea. Pop. 8,383.
R. G. W.

**TAOS.** *See* INDIAN TRIBES, NORTH AMERICAN (*Southwest*).

**TAPAJÓZ** [tapəzhɔ′s], a river which has its headwaters in the Brazilian state of Mato Grosso, about 95 mi. north of Cuiabá, the capital of that state. The Tapajóz flows northward for more than 1,000 mi. to enter the Amazon River at the town of Santarém. In its upper reaches, rapids and cataracts obstruct its course. Near its mouth, however, the river widens into a lake-like expansion about 10 mi. wide and over 70 mi. long. It is navigable for a distance of 175 mi. from its mouth, and regular steamship service is maintained. Belterra, the former Ford rubber plantation, is located 26 mi. south of the mouth of the Tapajóz, on the east bank.
P. E. J.

**TAPANULI** or **TAPANOELI** [tɑ′pɑnu′li], a residency on the northwest coast of Sumatra, in the province of North Sumatra in the Republic of Indonesia. Tapanuli residency includes Nias Island and covers a total area of 15,215 sq. mi. The capital of the residency is at Sibolga (pop. est., 10,765); other towns are Barus, Natal, and Padangsidimpoean. The residency is mountainous and includes Lake Toba in the northeast, the largest lake of Sumatra, regarded by the natives as holy. The territory in the interior around Lake Toba is known as Batakland, inhabited by the Bataks, a people at one time addicted to cannibalism, who are skilled artisans, shopkeepers, and farmers. Coffee, rubber, rice, tobacco, and maize, as well as fruits and vegetables, are cultivated, and stock raising is of importance. Tapanuli did not come under Dutch control until 1824. Nias Island, the largest island off the west coast of Sumatra, is almost entirely unaffected by western civilization. Pop. (est.), 1,043,000.

**TAPARELLI, MASSIMO.** *See* AZEGLIO, MASSIMO TAPARELLI, MARCHESE D'.

**TAPESTRY,** a form of hand-woven decorative fabric. Its chief materials are colored wools. The great development of tapestry was in Gothic France, but the art may be traced to ancient cultures. Its changing styles afford valuable sources of reference to old customs, performing a documentary as well as a decorative function.

From the earliest times tapestry played a role in decorative and domestic usage. The ceremonies of the courts and the Church were often luxurious yet practical, and the flexibility of woven pictures meant easy storage and transportation. Records show that tapestry was used for royal occasions, temporary chambers, religious celebrations, and simply as draughtwalls in the cold stone halls of the medieval European castles and châteaux. When the nobility traveled they took with them tapestries, often of huge size and in sets which could be arranged as movable partitions to form a chamber.

The fortunes of war have resulted in sets of tapestries becoming widely scattered, and many of the greatest importance were cut in fragments. Centuries may pass before these sections are recombined. A third type of accident that lost us many splendid examples of the weaver's art was deliberate burning in order to recover the gold and silver in their threads.

The subject-matter of tapestries has been virtually limited to three great groups: religious, mythological, and royal illustration. Scenes from bourgeois life are comparatively few, and in general tapestries have depicted exalted or glorified legends or events. Biblical subjects prevailed in the Gothic period: the Queen of Sheba, the Presentation of Jesus, and Saint Remi. By the seventeenth and eighteenth centuries, taste for these subjects had diminished, and Louis XIV and Louis XV had elaborate secular tapestry-rooms constructed in the châteaux of Chambord and Compiègne. Popular with smaller households were *verdures,* designs in which an allover foliage green prevailed. Similarly there developed a love of all-over patterns, known as *mille-fleurs.* These latter give a presentiment of the kind of floral wallpaper which was to appear in home decoration and largely to replace costly woven pictures.

Closely associated with the subject and development of tapestry was the governmental support of state looms and factories. Chief designers established traditional subjects

and styles, and the technique particular to each weaver's city contributed to the manner in which tapestry progressed. Thus French designs were determined by the ateliers of Aubusson and Gobelins. England, imitating the success of Henry IV of France in importing low-warp weavers from Flanders in 1607, built a tapestry center at Mortlake, a suburb of London, in 1620. The success of the Aubusson and Gobelin looms was equaled by Mortlake in its set from Raphael's cartoons of *The Acts of the Apostles,* now in the French National Collection.

The Month of December, *one of a series of Gobelin tapestries woven in silk and wool, probably between the years 1732 and 1737, under the direction of Michel Audran, from a set of sixteenth-century Flemish cartoons known as* The Months of Lucas.

COURTESY OF THE METROPOLITAN MUSEUM OF ART

*The Unicorn tapestries, remarkable for their design and beauty of coloring, are among the most extraordinary works of art of the sixteenth century. There are six tapestries and fragments of another in the Unicorn series, the five central pieces being made, in all probability, for Anne of Brittany in celebration of her marriage to Louis XII of France on January 8, 1499.*

*THE SEIZURE OF CASSANDRA BY AGAMEMNON*

*This example of English Mortlake tapestry was completed during the seventeenth century. It is one of a set of eight hangings known as the* Royal Horses, *woven of silk and wool, after cartoons by Francis Clein.*

Tapestry identification has been made exceedingly problematical by the fact that, even in the Middle Ages and the Renaissance, sets of designs were repeatedly copied and plagiarized. However, poor reproductions or adaptations of old designs during the period of 1870-1940 makes it easy to judge tapestry quality, for then the weavers employed designers of the weakest and most derivative mannerisms; and the Gothic mythological quality was so sentimentalized as to make those tapestries definitely meretricious. The question of taste in tapestries is relatively complex, as in painting, but it will serve the speculator to consider if the woven-thread character of the material has been respected, and its essential flatness has not been tortured into illusionary depth. Most trained critics would immediately prefer those Gothic and early Renaissance tapestries which are clearly flat-textured designs to those technical triumphs of the Victorian weavers which ape so needlessly the devices of form and perspective associated with illusionary oil-painting.

Tapestries, especially from France, received a popular yet intelligent acclaim when, in 1946, a superb collection of ancient and contemporary tapestries was exhibited in Paris under the auspices of the Louvre. These outstanding examples from private and public collections were shown in Paris, Amsterdam, Brussels, London, New York, and Chicago, and for the first time an adequate view of this craft could be enjoyed and studied. Among the many shown were the incomparable fourteenth-century Apocalypse tapestries (the treasure of Angers), the series of the legend of St. Stephen from the Cluny Museum in Paris, and also from the Cluny Museum the six tapestries representing the lady with the unicorn. This exhibition again showed tapestry as a vital and stimulating art form, rescuing it from the despised power-loom imitations and the jejune facsimiles so long offered in auction rooms. Twentieth-century individualism in the arts affected tapestry design. Tapestries woven during World War II in France are characterized not so much by the loom (as Gobelin, Arras, or Beauvais) as by the style of the artist-designer himself. The weaving done at Aubusson in the 1940's brought a startling change to tapestry production. Woven after designs made by painters (Lurcat, Gromaire, Saint-Saëns, Dufy, Matisse, Guignebert, Marchand, Jean Picart Le Doux, and others), these tapestries surprised by their individualistic distortions and violence of creative originality. The ancient art of pictorial weaving was refreshed by the liberal and experimental devices and abstractions of the modern movement of the twentieth century. However, tapestry will continue its tradition of a craft halfway between functionalism and decorative enrichment.

**Techniques.** The techniques of tapestry weaving are comparatively simple. However involved and rich the tapestry, its designs are created by a rather elementary over-and-under weaving of colored wool threads on a cotton warp. (Carpet weaving is similar, but its threads are knotted and clipped to form the pile.) All tapestries are woven on looms arranged either vertically (*haute-lisse*) or horizontally (*basse-lisse*). The choice is determined by speed and cost. In each case the weaver rolls up the finished part on a drum roller and proceeds by a scrupulous study of the design or cartoon directly before him. The weaver (*tapissier*) himself almost never created the compositions, and was at one time legally forbidden to attempt to do so. Designs were largely the product of painters, and until the 1940's they were based upon conventionalized symbols and allegorical figures.

The weaver simply interweaves with a shuttle (or *flute* or *broche*) his wool strands, which closely match the tones of the cartoon. These tones were few in early tapestries, but rose to about 14,600 shades, until simplification in the 1940's reduced the colors to about 50 shades. Aniline dyes presented problems of fading, but light-fast hues of shrill intensity were frequently employed, and the laboratories of the Gobelins factory made careful research into the problem of color.

One of the technical trials of tapestry weaving is the low-loom problem of inspecting the "right" side of the result, by mirror reflections, beyond the warp threads. Another technical problem is the modeling of form to resemble three-dimensional mass. This must be done by crosshatching the stitches. With extreme detail, an effect of realistic oil painting, achieving even the contours of portraiture, can be contrived. This is fortunately no longer a desired dexterity, and even metal threads are rarely used.

The preservation and care of tapestries is akin to that of carpets and rugs. When not hanging, they should be rolled but not folded. When hung they require stiff webbing to which the rings are attached. Old tapestries must have linings, which should be well reinforced with diagonal stitching. Tapestries should not be hung as flat as a wall, but loosely; and to frame tapestries is to sacrifice their fabric quality. The washing, dusting, and repairing of tapestries is properly the work of museum experts. W. F. Ba.

**TAPEWORM,** a name given to cestode worms belonging to the genus *Taenia* and allied genera, parasitic in the adult stage in man and animals. The long, flat body is composed of a knoblike head, the scolex, and a great number of seg-

ments called proglottids. The head is furnished with suckers and frequently with hooks. Behind the scolex is a short neck followed by the proglottids which gradually increase in size from the anterior to the posterior end. There is no digestive tract; the dissolved food is absorbed through the body wall. Most of the tapeworms are hermaphroditic, each segment containing male and female organs. The life history is rather complicated, usually involving one or more intermediate hosts in which larvae mature. The most important tapeworms affecting man are the pork tapeworm, *T. solium,* and the beef tapeworm, *T. saginata.* A common fish tapeworm that infests man is *Diphyllobothrium latum.* Tapeworms are found parasitic in many other vertebrate animals.

R. F. N.

**TAPIOCA** [tæpio′kə], the starch extracted from the bitter cassava, *Manihot esculenta,* and the sweet cassava, *M. aipi.* It is obtained from the thickened rhizome, and is sold in coarsely granular form. When cooked, it swells, thickens, and becomes translucent. Tapioca, quite nutritious and easily digestible, forms an excellent diet for the sick and convalescent.

J. A. Bo.

**TAPIR** [te′pər], a clumsy-looking mammal of the genus *Tapirus* in northern South America; of the genus, or subgenus, *Tapirella* in Central America; and of *Acrocodia indica* in southeastern Asia and Sumatra. The tapir has an arched back, a very short tail, and a piglike head in which the muzzle is drawn out in a short, flexible trunk. The legs are short, and the toes, 4 on each front foot and 3 on the rear, are enclosed in separate, horny hoofs. American tapirs are entirely deep brown in color. The Asiatic species is distinguished by a broad white area on the body, while the fore parts and lower hindquarters are brownish black. Somewhat larger than the New World tapirs, the arched back of this species is 3 to 3½ ft. above the ground.

Tapirs inhabit dense, swampy forests, mostly along rivers, and feed on shrubs, herbs, and fruit. They swim, or wallow in mud to cool their thinly-haired skins. Being very shy, they are rarely seen. The flesh is not particularly appetizing, and tapirs are not often shot except for their hides. In Asia, their chief enemies are tigers, and in America they are preyed upon by jaguars and cougars.

**TAPUYA.** *See* Indian Tribes, South American (*Principal Linguistic Families*).

**TARABULUS ESH SHAM.** *See* Tripoli.

**TARAHUMAR.** *See* Indian Tribes, North American (*Southwest*).

**TARAKAN** [tɑ′rɑkɑ′n], a small island off the northeast coast of Borneo, Republic of Indonesia, in the Celebes Sea. The island, with an area of approximately 118 sq. mi., is noted for its oil fields, which produce extremely high-grade oil, some of which requires little or no refining. Tarakan was taken by the Japanese in January of 1942, but the Dutch destroyed the oil wells and refining installations. Australian forces recaptured the island in May 1945. Pop. 11,600.

A. L. R.

**TARANCHI.** *See* Asiatic Tribes (*Ural-Altaic*).

**TARANTELLA** [tærəntɛ′lə], a very lively dance in 6/8 time, deriving its name either from the town of Taranto, in southern Italy, or from the tarantula which infests that region. Popular legend once held that the bite of this spider caused a disease known as tarantism which could be cured only by the frenzied dancing of the tarantella. Modern tests have shown the bite of this spider to be relatively harmless, but no doubt autosuggestion, coupled with the great physical exertion of the dance, played a part in allaying the hysterical fear caused by a bite. With its rapid, never-ceasing triplets, the tarantella is musically little different from the saltarello. Well-known examples in art music have been composed by Liszt, Chopin, Weber, and Daniel Auber, and the finale of Mendelssohn's "Italian" Symphony approaches the tarantella in style.

P. N.

**TARANTO** [tɑ′rɑnto], an Italian naval base, the capital of a province formerly of the same name but now known as Ionio, in Apulia, southeastern Italy, at the head of the Gulf of Taranto. The Greek colony of Taras, founded by settlers from Sparta on the site of the present city in the eighth century B.C., grew in power and wealth and at its height had a population of 300,000 living within a perimeter of 10 mi. After wars with the neighboring Lucanians, Messapians, and Bruttians, the Greeks had to face Rome on land and sea, sometimes in league with their late enemies as well as with Epirus and Carthage. The Romans finally subjugated Taras in 272 B.C., took huge quantities of booty, and renamed the city Tarentum. After the disintegration of the Roman Empire, there came a succession of alien invaders: Goths, Lombards, Byzantines, Arabs (who took the city three times and in 927 completely destroyed it), Normans, Hohenstaufens, Angevins, Aragonese, Spanish Hapsburgs, Bourbons, and the French under Napoleon. Few traces of the extensive Greek and Roman cities remain. The Romanesque cathedral, begun in the fourth century and rebuilt in the eleventh century, and the castle, of Byzantine origin and later enlarged by the Spaniards, are the two most interesting medieval remains. During World War I, Taranto was Italy's most important naval base and was much used by the Allied fleets. It became a provincial capital in 1923, which, in addition to its role as naval base, caused its rapid growth between World Wars I and II. On the night of Nov. 11-12, 1940, the British inflicted heavy damage on the vessels at anchor there and destroyed Italian naval superiority in the Mediterranean. Early in September 1943 the main body of the British Eighth Army landed at Taranto and pushed north across Apulia.

The city is built on two peninsulas, between which lies an island that once formed part of the southern peninsula but was separated from it by a canal dug in 1480 for reasons of defense. Now the two peninsulas and the island are connected by short bridges, under which flow the waters joining the gulf and the Mare Piccolo (Small Sea). The nearly landlocked Mare Piccolo is about 4 mi. long, and the Italian naval base is on its southern side, the eastern edge of Taranto. The outer bay, or Mare Grande, is almost circular,

*Castello San Angelo, a tenth-century fortification which guards the entrance to the Mare Grande, a bay of the Gulf of Taranto*

COURTESY OF THE ITALIAN NATIONAL TOURIST OFFICE

enclosed by shoals and the islands of St. Peter and St. Paul, but having an entrance about a mile in width to accommodate large ships. Access to the Mare Piccolo and its installations is through the canal, past a swinging bridge. The modern city has expanded to the north and southeast of its medieval site on the island. Taranto is now a railroad center, a commercial port of importance, and the natural market for the agriculture of the surrounding region. There is extensive fishing, and oysters are dredged in the Mare Piccolo. The city has an institute of marine biology. A number of industries connected with shipping, foodstuffs, and the building trades have developed in Taranto since 1900. Pop. (off. est. 1947), 181,726. R. G. W.

**TARANTULA** [tərа′ntshulə], a hairy spider of the family Theraphosidae, the largest of the spiders. Theraphosids inhabit the warmer parts of the world; the name tarantula is applied particularly to those of the southern and

*TARANTULA, EURYPELMA EMILIA, A LARGE VENOMOUS SPIDER OF TROPICAL AMERICA*

COURTESY OF THE AMERICAN MUSEUM OF NATURAL HISTORY

western United States. In Europe the name is given to a large wolf spider belonging to another family. Tarantulas usually live in holes in the ground or under rocks. They range in size from an inch to two inches or more in body length, and may reach a leg spread of eight or nine inches in some of the tropical "bird" spiders. They usually eat large insects, mostly beetles. They are nocturnal in their activities and are seldom seen, except when rain forces them from their burrows or when the males rove during the mating season. Though shy and furtive, tarantulas may inflict a painful bite when captured in the hand. Most of those occurring in the United States are not seriously poisonous, the bite seldom being worse than the sting of a wasp. Some tropical forms are capable of killing small animals. *See also* ARACHNIDA; SPIDER. W. I.

**TARAPACÁ** [tɑ′rɑpɑkɑ′], the northernmost province of Chile, bordered on the north by Peru (Tacna Department), on the east by Bolivia (La Paz, Oruro, Potozí departments), on the south by Antofagasta Province, and on the west by the Pacific Ocean. Tarapacá originally belonged to Peru but was ceded to Chile at the end of the War of the Pacific (1879-1884). The province has a total area of 21,346 sq. mi., largely composed of desert and narrow valleys. Two mountain ranges fringe the province: the Cordillera Occidental of the Andes on the east, and a lower coastal chain sloping into the shoreline on the west. The larger cities are the important coastal ports of Arica, Pisagua, and the capital, Iquique. Water and vegetation are scarce, and the major industry is the extraction of nitrate of soda from the province's rich mineral fields. Silver is also mined in the coastal range in the vicinity of Iquique, principal shipping point for this industrial area. Pop. (off. est. 1945), 99,724. S. G. I.

**TARAWA** [tərɑ′wə; tɑ′rɑwɑ′], a chain of long and extremely narrow coral islets, about 18 mi. long and 13 mi. wide at the widest point of the atoll, in the Gilbert Islands. It is located at 1° 30′ N. lat and 173° E. long., southwest of Hawaii in the central Pacific Ocean. Tarawa is the headquarters of the Resident Commissioner of the Gilbert and Ellice Islands Colony of Great Britain, of which it is a part. It was proclaimed a British protectorate at the request of the native governments in 1892, and annexed by Britain Nov. 10, 1915. Immediately after Pearl Harbor, Tarawa was taken by the Japanese and remained under their control until liberated by United States Marines Nov. 23, 1943. The defeat of the Japanese on Tarawa was accomplished only after bitter fighting and heavy casualties, marking the battle as one of the severest in the Pacific during World War II. The temperature ranges between 80° F. and 90° F. during the day and 70° F. at night. The islets are covered with tropical flora dominated by coconut palms. Pop. 1936, 2,640. R. G. B.

**TARAZONA** [tɑ′rɑthoˈnɑ], a city in Spain, located about 50 mi. northwest of the city of Zaragoza, in the western part of the province of Zaragoza, in Aragon. It is situated on a hill, surrounded by a plain through which flows the Queiles River, a tributary of the Ebro. Originally called Turiaso by the Romans, it was an old fortress town which played an important part in the Castillian-Aragon War of the fourteenth century. The city is the see of a Roman Catholic bishopric, and the cathedral dates back to the twelfth century. The Romanesque church of La Magdalena is an important tourist spot and the library of Tarazona is noted for its collection of historical literature. It is the center for the agricultural region of the surrounding plain, on which are raised grapes, cereals, and vegetables. The chief industries include the processing of wool, grapes, and lumber from the near-by hills. Pop. 1940, 11,237. L. M. A.

**TARBES** [tɑ′rb], capital of the department of Hautes-Pyrénées in southwestern France, located about 75 mi. southwest of Toulouse on the left bank of the Adour River, with views of the hills of Armagnac to the north and of the Pyrenees to the south. First known as Bigorra, seat of the counts of Bigorre, it was occupied by the English between 1360 and 1406. During the Wars of Religion (1569) it suffered at the hands of forces led by Count Gabriel de Montgomery, a general appointed by Jeanne d'Albret, Queen of Navarre, to establish Protestantism by force throughout her dominions. It suffered again when overrun by the forces of the Roman Catholic League in 1592. The twelfth-century cathedral, known as La Sède, built of brick, stone, and rolled pebbles, is in mixed styles, with a Romanesque apse and a Gothic cupola. The fifteenth-century cloister of a former Benedictine abbey, brought from neighboring St.-Sever-de-Rustan, stands in the Jardin Massey, which also contains a museum of paintings, sculpture, and antiquities. At Tarbes are an important arsenal and an artillery school. Among the industrial enterprises are forges, tanneries, pottery works, and electrical equipment, and chemical plants. Pop. 1954, 40,242. W. McE.

**TARBORO** [tɑ′rbʌrə], a town in eastern North Carolina, the county seat of Edgecombe Co., situated on the Tar River, about 65 mi. east of Raleigh. The town was founded and incorporated in 1760, and in 1950 it was governed by a mayor and council. The municipally-owned pasteurizing plants are a unique feature of the community, which has rail transportation supplied by the Atlantic Coast Line and

the East Carolina railroads. Tarboro is a marketing center for the tobacco, cotton, peanuts, beans, and corn grown in the district. The local plants manufacture cotton cloth, hosiery, cottonseed-oil and peanut products, and veneered panels. Pop. 1950, 8,120.

**TARDE, GABRIEL** [ta′rd] (1843-1904), French sociologist and lecturer in the *Collège libre des Sciences Sociales,* was born in Sarlat, in Dordogne, France, on Mar. 12, 1843. Educated at home and in Paris, for many years he taught in Sarlat, serving also as a local judge. His experience as magistrate led him to reject the prevailing theories of a biological basis for criminality and to seek causes of crime in social behavior. In the 1880's he moved to Paris, aided in founding the *Archives d'anthropologie criminelle* in 1886 and later became its editor. As a result of his studies and writings he acquired an international reputation as a criminologist. He published *La Criminalité comparée* (1886) and *La philosophie penale* (1890). As chief of the Bureau of Statistics of the Ministry of Justice, to which position he was appointed in 1894, he made extensive studies of criminality. Several years after this appointment his interests broadened and he developed a system of sociology based on imitation. Toward the end of his life, 1899-1904, he was professor of modern philosophy at the Collège de France.

His sociological theory as outlined in *Les Lois de l'imitation* (1890) and *Les Lois sociales* (1898) is built on the thesis that the fundamental social act is imitation of one person by another. His ideas of imitation, however, are quite complex and include adaptation, or invention, and even opposition as special forms of imitation, in addition to the more familiar notion of repetition of observed actions. Imitation, he taught, proceeds in a wavelike fashion and these waves may either reinforce or diminish each other. Thus an invention is the fortunate coincidence and reinforcement of waves put into motion by creative persons. His philosophy was essentially individualistic and was attacked with vigor by the more group-minded Émile Durkheim, with the result that French sociology was split into opposed schools. He died in Paris, May 15, 1904. H. E. M.

**TARDENOISIAN** [tɑrdənɔi′ziən], a European culture of Mesolithic type, after Fère-en-Tardenois, Aisne, France, and characterized by microlithic flints, often of geometric forms, found in France, the Netherlands, Britain, Germany, Poland, and south Russia, commonly on open sandy sites or on exposed uplands, but also in caves and in coastal middens as at Téviec. In France the Tardenoisian culture is younger than the Azilian and overlaps in time with Neolithic cultures in the same country. The Tardenoisians continued to maintain a Mesolithic mode of life on the poorer soils, while the earliest farmers were establishing themselves on more fertile lands. J. G. D. C.

**TARDIEU, ANDRÉ PIERRE GABRIEL AMÉDÉE** [ta′rdyœ′] (1876-1945), French statesman, was born in Paris Sept. 22, 1876. He was admitted to the École Normale Supérieure in 1895, but caused a sensation by leaving the school immediately. He became a journalist, specializing in foreign policy problems, taught at Harvard University in 1908, at the École des Sciences Politiques in 1909, and was appointed professor of political science at the École Supérieure de Guerre in 1911. A member of the Chamber of Deputies from 1914 to 1924, he nevertheless fought in World War I as a reserve officer, was three times wounded and three times cited for bravery. He was sent to the United States with the Joffre mission in 1917. Shortly afterwards, he became closely associated with Georges Clemenceau, and was his chief adviser in the negotiations that led to the Treaty of Versailles. He thus played a particularly important part in the drafting of the political and territorial clauses of that treaty. He was minister of liberated regions, 1919-1920, minister of public works, 1926-1928, minister of the interior, 1928, premier, 1929-1930, minister of agriculture in 1931, and premier again in 1932. Throughout this period he stood for the type of strong policy which had been represented by Clemenceau, and he fought vigorously against all attempts to revise the Versailles Treaty. From 1933 on, he became outspoken in his criticism of the current French régime, although, after the riots of February 1934, he served as minister without portfolio in the conciliation cabinet headed by Gaston Doumergue (February-November 1934). In 1936 he refused to take part in the electoral campaign, and subsequently bitterly attacked the parliamentary system as then practiced in France. Early in 1939, shortly before World War II, Tardieu's health broke down and he retired to Menton, a town on the French Riviera. There he died on Sept. 15, 1945. G. E. L.

**TARENTUM** [tərɛ′ntəm], a borough in Allegheny Co., in southwestern Pennsylvania, situated on the Allegheny River, 21 mi. northeast of Pittsburgh. Founded in 1796 by Felix Negley, who built a grist mill at the mouth of Bull Creek, the community was named after the ancient Roman seaport; it was incorporated as a borough in 1842. Community affairs are administered by a burgess and council. Transportation facilities are provided by the Pennsylvania Railroad. The first petroleum used commercially in the United States was produced in Tarentum. Thomas and Samuel Kier in 1847 leased a piece of land near Tarentum on which to drill for salt, and, while drilling, discovered oil, which they bottled and marketed as "Petroleum or Rock Oil," medicine for many ills. Samuel attempted to distill petroleum, and in 1855 he built his first successful still. He sold the oil for illuminating purposes and perfected an oil-burning lamp. During a visit to Pittsburgh in 1857 Colonel A. C. Ferris of New York saw the Tarentum oil burning in a lamp, and he arranged with Kier to market it in New York. In 1858 the production of crude oil in Tarentum amounted to approximately 1,000 barrels, at a price averaging $30 a barrel. Besides petroleum, there are natural resources of gas, bituminous coal, sand, and gravel in the district, and these are the basis of the borough's development as a leading steel, glass, chemical, and bronze manufacturing community. Coal mining is one of the most important industries in the locality. Pop. 1950, 9,540.

**TARGET SHOOTING,** a competitive or individual sport in which rifles or pistols are fired for accuracy at a fixed objective. The sport is as old as firearms and is practiced throughout the world.

In America, turkey shoots at festive gatherings and Kentucky long-rifle matches were early counterparts of modern target shooting. Target shooting as a national sport had its beginning in 1871 when a group of state militia officers and Civil War veterans organized the National Rifle Association at Creedmor, Long Island, N. Y. This association expanded steadily and is now the parent organization of well over 4,000 units, with more than 250,000 individual members. In 1902 the National Matches were established by an Act of Congress. These National Matches are rifle and pistol target-shooting competitions conducted annually in September at

Camp Perry, Ohio, under the supervision of the United States Army.

**Types of Modern Matches.** Practically all modern competitive matches are standardized under rules and specifications of the National Rifle Association, which has also played an important role in the development of the National Matches. This organization conducts its own championships at the Camp Perry Nationals each year and pays the expenses to the matches of winners in regional competitions. It awards cash prizes and trophies at the Nationals.

Target-shooting matches take many forms. Some are for specific personnel only, such as service, police, or civilians, while others are open to all who wish to compete. The shooters are grouped into various classifications: master, expert, sharpshooter, marksman, and tyro—depending upon their previous records at official matches. Matches are conducted at various ranges. Service and other .30-cal. rifles are shot over 200- and 500-yd. ranges. Small-bore competitors, a group making up the majority of rifle target shooters, generally fire over 50- and 100-yd. ranges. Indoor matches, such as those conducted for collegiate and scholastic competition in the spring of the year, are shot on 50-ft. ranges.

In rifle target shooting, each competitor fires from four positions: prone, sitting, kneeling and offhand, or standing. He is judged on his aggregate score from these four positions.

Pistol target matches are conducted for .45-cal., .38-cal. and .22-cal. hand guns. In a typical match, each shooter fires ten slow-fire shots at 50 yd., ten timed-fire at 25 yd., and ten rapid-fire at 25 yd. He is judged on his aggregate score.

**Equipment.** The type of cartridge, such as the .22-cal. long-rifle match ammunition used by small-bore target shooters, is strictly defined by match regulations. Also, the type of sights which may be used in various matches is specified. Matches are divided into two groups: one in which metallic sights only are allowed, and the other in which any type of sight is permitted. The first classification eliminates optical sights. In the open matches where any sights are permitted, however, optical telescope sights of from 8 to 24 power are commonly employed.

Rifles are open to considerable variation according to individual tastes and requirements. The modern target rifle is generally much heavier than a corresponding hunting rifle. In the .22-cal. category, for instance, a hunting rifle will weigh from 5 to 7½ lb., while the target rifle may weigh from 11 to 17 lb. This added weight produces less barrel vibration and makes it possible for the shooter to hold the rifle steadier; however, a gun of this weight is impractical to carry in the field. D. Ho.

**TARGUM** [tɑ′rgʌm; tɑrgu′m] (pl. Targumim), the Hebrew and Aramaic word for translation. Specifically, the term is applied to Aramaic translations of the Bible. When Hebrew was replaced by Aramaic as the spoken language of the Jews (probably shortly before the beginning of the Christian Era), the need for targumim arose. In synagogues of the early centuries of the Christian Era, a person was employed for the specific purpose of translating scripture into the vernacular as it was read. In time, targumim were written down.

The most important of extant targumim is the *Targum Onkelos* of the Pentateuch. The name *Onkelos* is a distorted form of *Aquila;* it is possible that it means "a faithful rendering," "in the manner of Aquila," but it is more probable that it was used through confusion with a reference to Aquila's Greek translation of the Bible. This targum is also called the Babylonian Targum, being referred to in the Babylonian Talmud as "our targum." Linguistic evidence suggests that it may have been begun in Palestine, but it was completed in Babylonia, reaching its final form at about the end of the fifth century. It is regarded as authoritative and is commonly printed alongside the Hebrew text in Hebrew Bibles. It is a rather faithful translation, but it generally avoids anthropomorphisms and in many cases employs euphemisms. Other extant targumim of the Pentateuch are the fragmentary Jerusalem Targum and the Pseudo-Jonathan, Targum, the latter so called from having been wrongly attributed to Jonathan ben Uziel. These, incorporating much Haggadic and exegetical matter are far less literal than the Onkelos.

In addition, there are the Targum Jonathan to the prophetic books of the Bible and individual targumim to all the books of the Hagiographa except Daniel, Ezra, and Nehemiah, for which no targumim have been discovered. The general character of these targumim is interpretive and exegetical rather than literal. D. G.

**TÂRGU-MUREŞ** [tɪ′rgumu′reʃ] (Hung. Maros-Vásárhely), a city in Transylvania, north central Romania, on the Mureşul River about 165 mi. northwest of Bucharest. It was once the capital of the territory of the Szeklers, and an old citadel on a hill overlooking the city contains a beautiful church in Gothic style built about 1446. The city's trade is chiefly in timber, petroleum, grain, wine, tobacco, and fruit. Its most important industries are distilling and the refining of sugar beets. Pop. (off. est. 1948), 47,043. S. A.

**TARIFF.** *See* Trade and Exchange (*Trade Volume*).

**TARIM DARYA** [dɑ′ri′m daryɑ′], a river about 1,250 mi. long, one of the larger rivers in south central Asia. The Tarim rises in the high Karakoram Range near the Karakoram Pass between Kashmir, India, and Sinkiang Province of China. The river flows generally northward across the mountains and in the Tarim Basin bends to the northeast and east. It then decreases in size as it flows across the dry Tarim Basin and eventually disappears in a series of small swamps and lakes west of Lop Nor. The river, with its major tributaries—the Khotan Darya, the Kashgar Darya, and the Yarkand Darya—forms the most important source of water and is a transportation route across Sinkiang and the northern edge of the Takla Makan Desert. The chief city on the Tarim is Soche (Yarkand), but there are numerous small settlements along its banks, where the combination of alluvial soil and water makes agriculture possible. The Tarim Basin comprises an area of about 350,000 sq. mi. J. E. F.

**TARKINGTON, (NEWTON) BOOTH** (1869-1946), American novelist, was born July 29, 1869, in Indianapolis, Ind. He attended Phillips Exeter, Purdue, and Princeton, where his artistic versatility was demonstrated by college success in music, drawing, and writing. This ability he soon applied more specifically to literature as a profession. His first novel, *The Gentleman from Indiana* (1899), concerning a country editor's crusade against corrupt politics, is one of his best; but it was the second, *Monsieur Beaucaire* (1900), a pseudo-historical romance, that secured his reputation. Of some thirty other novels, the outstanding are *The Conquest of Canaan* (1905); *Penrod* (1914), *Penrod and Sam* (1916), and *Seventeen* (1916), all humorous pictures of the American adolescent; and *The Magnificent Ambersons* (1918) and *Alice Adams* (1921), studies of social and economic forces, both of which won Pulitzer Prizes. Tarkington was gener-

ally faithful to Middle Western actuality, but his realism is sentimental and given to flattering the popular faith in the eventual triumph of virtue. His plots are commonly subordinated to the analysis of character.

Tarkington tried other genres, but without notable success. *In the Arena* (1905) is a collection of stories about political life; *Looking Forward* (1926), a book of essays; and *The World Does Move* (1928), a volume of reminiscences. *Tweedles* (1923), written in collaboration with Harry Leon Wilson, is the best known of his plays. In 1930

BOOTH TARKINGTON

BROWN BROTHERS

Tarkington lost his sight, which was later partially restored. He spent his winters in Indianapolis and his summers in Kennebunkport, Maine, where his beached schooner, the *Regina,* served as a workshop. He died May 19, 1946, in Indianapolis. W. P. R.

**TARLAC** [tɑ′rlɑk], the name of both a province and its capital, located in the central part of Luzon, in the northern part of the Republic of the Philippines. The province is bordered on the north by Pangasinan Province, on the east by Nueva Ecija, on the south by Pampanga, and on the west by Zambales. The eastern slopes of the Zambales Mountains form the western part of the province, where corn and tobacco are the chief crops, while the central and eastern section is a fertile plains region, producing rice, sugar, vegetables, and pineapples. Under Spanish rule Tarlac was originally included in Pampanga province. Part of it became a military command in 1860; the whole area joined the revolt against Spain in 1896. Civil government was established by the United States in 1901. During World War II the province was occupied by the Japanese in December 1941 and liberated by American forces in January 1945. Pop. 1948, 327,018.

The town of Tarlac, administrative center of the 42 barrios or districts in the province, is situated on a level plain about 65 mi. northwest of Manila, on a tributary of the Agno River and on the Manila-Dagupan Railroad. Founded in 1686, Tarlac is the chief trade center of the region. Its industries are the processing of rice and sugar cane, lumbering, and the manufacture of pottery and wooden shoes. Tarlac is a municipality consisting of three barrios: San Roque, in the south, a residential and administrative area; and, in the north, Matatalaib, the business district, and San Nicolas, an industrial and residential district. Principal buildings are the provincial capitol, the municipal building, and the Manuel Roxas Memorial Library. The hospital, built in 1924, was the first provincial hospital in the Philippines. The town was partially destroyed by the Japanese in World War II. Pop. 1948, 64,597.

**TARN** [tɑ′rn], a department in southern France, with an area of 2,231 sq. mi., bounded by the departments of Aveyron on the northeast, Hérault on the southeast, Aude on the south, Haute-Garonne on the southwest, and Tarn-et-Garonne on the northwest. The climate generally is mild, with long summers and short winters. Tarn is crossed by offshoots of the Cévennes Mountains in the southeast, plains in the southwest, and a plateau in the north which is part of the Plateau Central. The Aveyron, Tarn, and Agout are the chief rivers. Cereals, fruits, vegetables, and mulberry trees and chestnuts from the environs of Lavaur are the chief agricultural products. There is excellent pasturage in the southern valleys of the Agout and its tributaries, where horses are bred for the cavalry and mules for shipment to Spain; cattle and sheep also are bred, and hogs are fattened. Mazamet, center of the textile industry, is foremost in Europe for shearing wool from sheep hides imported from Australia and America. More than 30,000 tons are treated here annually. Woolens are manufactured at Albi, Lavaur, and Réalmont; cheaper textiles at Vabre and Brassac; and clothing at Castres. There is an extensive furniture industry, specializing in children's furniture, at Albi, Rabastens, and Castres. At Albi, the prefecture, on the left bank of the Tarn, is the Gothic cathedral of Ste. Cécile (1282). At Cordes, founded in 1222, there are buildings dating from the fourteenth century. Tarn exports sparkling wines from Gaillac, morocco leather products, and woolen and nappy fabrics. Tarn was formed in 1790 from part of the old province of Languedoc. Pop. 1954, 308,197.

**TARN-ET-GARONNE** [tarne′gɑ′rɔ′n], a department in southwestern France, with an area of 1,440 sq. mi. The department is bounded by the departments of Lot on the north, Aveyron on the east, Tarn and Haute-Garonne on the southeast, Gers on the southwest, and Lot-et-Garonne on the northwest. The climate is mild. There is a plain bounded by the Tarn, Garonne, and Aveyron rivers, and there are hills in the northeast. Agricultural products include maize, wheat, rye, barley, flax, hemp, mulberry trees, plums, and apricots. Sheep, mules, horses, and cattle are bred. The department is noted for brandy and cavalry horses. Freestone is produced at Bruniquel, St. Antonin, and Caussade; tanning chemicals at Bruniquel; silk and lingerie at Montauban and Bruniquel; cheese at Montauban and Valence-d'Agen; wax candles and furniture at Montauban; and hats from imported Oriental straw at Caussade, Montauban, and Septfonds. The principal exports are fruit, truffles, vegetables, and wine. Montauban, the prefecture, has a fourteenth-century brick church; at Moissac is the Church of St. Pierre (1063); and at St. Antonin is a restored twelfth-century Hôtel de Ville. Tarn-et-Garonne was formed in 1808 from the old provinces of Guyenne, Gascogne, and part of Languedoc. Pop. 1954, 172,379. S. Van V.

**TARO** [tɑ′ro], an herb, *Colocasia esculenta,* also called dasheen or elephant's-ear, from the huge, bright green leaves which are often 3 ft. long and nearly as wide. This herb is of the arum family, widely grown in the tropics for the tubers, which are used as food, and elsewhere for ornamental purposes. It is a native of Fiji and Hawaii, where the starchy

root is fermented and made into a food called *poi*. In Japan, taro tubers are eaten like potatoes, and the young shoots and leaves are used as a vegetable. The Egyptian taro, *C. antiquorum*, cultivated from ancient times, is a native of India, but is inferior as a food to the Pacific taro. J. C. Wis.

**TARPON** [tɑ′rpɒn], *Tarpon atlanticus*, a silvery, large-scaled fish of the family Elopidae. Also called silverfish, it resembles a large herring. It has a bony gular plate between the lower jaws and a prolongation of the last dorsal fin rays. It is widely found in the Atlantic from Brazil and the west coast of Africa northwest to Long Island, and is especially common in coastal areas in the Caribbean region where it often enters the rivers. It is also found in Lake Nicaragua.

COURTESY OF THE U. S. FISH AND WILDLIFE SERVICE

*Tarpon, Tarpon atlanticus, a marine fish common to the coastal waters of Florida, the Gulf of Mexico, and the Caribbean area*

Swimming with great speed, the streamlined body is propelled by a powerful forked tail. The tarpon feeds on fishes. It often leaps clear of the water to a vertical height of 10 ft., and horizontal leaps of 20 ft. are on record. As a big game fish, it has a well-deserved world-wide reputation. A record specimen caught on rod and reel in Mexico weighed 247 lb. and was about 7.5 ft. long. A still larger one, more than 8 ft. long and over 350 lb., was netted in Florida waters. Little use is made of the flesh, but the large attractive scales are used in making ornaments. A smaller related species, the oxeye, *Megalops cyprinoides*, occurs in the Indian and Pacific Oceans. E. C. R.

**TARQUINIA** [tɑrkwi′nyɑ], a town in the province of Viterbo, central Italy, about 45 mi. northwest of Rome. The town is located on a hill at an altitude of almost 500 ft. along the left bank of the Marta River, not far from its mouth on the Tyrrhenian Sea. Tarquinia was an important Etruscan and Roman center. Its origins were in the tenth century B.C., coinciding with the development of the Iron Age civilization in Italy. During the following three or four centuries, Tarquinia became the capital of a powerful state, part of the great Etruscan confederation, extending from the sea to Lake Bolsena. According to tradition, the royal dynasty of the Tarquinii fought against the rising power of Rome in a number of long and bitter wars about the middle of the fourth century B.C. Finally, Tarquinia entered into Rome's political sphere of influence as a federated state. Later, it became a free municipium, achieved great importance in the latter part of the first century of the Christian Era, and became the seat of a bishopric. After a period of decadence, the town was deserted by the remaining inhabitants, who moved to a near-by hill, the medieval fortified town of Corneto (which in recent times has taken the name of Tarquinia). During the Middle Ages, Corneto played a fairly important role in the struggles between the emperors and the popes, siding with the latter. In the fifteenth century, the town was ruled by the Vitelleschi family and later became part of the popes' domain.

Excavations conducted since about 1900 have led to the discovery of remains of the Etruscan city. Especially important is the necropolis, with subterranean chambers richly decorated, many of their paintings remarkably preserved. These paintings—of banquets, games, religious ceremonies, the funeral of the deceased, and the trip to the other world in the Etruscan conception of it—offer the best available documents of the development of Etruscan art and civilization between the sixth and the second century B.C.

The medieval imprint is still evident in the high walls, narrow streets, and many towers. There are remnants of the castle of Countess Matilda of Canossa; even better preserved are the Church of Santa Maria in Castello, built in the early twelfth century by Lombard architects, and the Palazzo Vitelleschi, erected in 1439 by Cardinal Giovanni Vitelleschi. Pop. (off. est. 1947), 9,776. L. J. W.

**TARQUINIUS** [tɑrkwɪ′niəs], the name of two legendary kings of Rome.

**Lucius Tarquinius Priscus.** Lucius Tarquinius Priscus, fifth legendary king of Rome (616-578 B.C.), was probably of Greek origin. He married a Tuscan lady of rank and influence and settled in Etruria, later moving to Rome, where he was admitted to Roman citizenship. He became the confidant of Ancus Marcius, King of Rome, and was elected his successor. He fought the Sabines and conquered Latium. During his reign many public works were erected, including the Roman cloacae and the Circus Maximus, where the great Roman games were held. He is credited with initiating the Roman triumphal parade, which he led dressed in a robe of purple and gold, seated in a chariot drawn by four horses. He instituted political changes in Rome, particularly in increasing the number of senators to thirty and doubling the number of knights. He is said to have begun the capitol in order to honor Jupiter, Juno, and Minerva. He was assassinated at the instigation of the sons of Ancus Marcius.

**Lucius Tarquinius Superbus.** Lucius Tarquinius Superbus, seventh and last of the legendary kings of Rome, (534-510 B.C.) and son of Lucius Tarquinius Priscus, was too young to succeed his father. He coveted the throne and spent much of his youth intriguing against his brother-in-law, the king Servius Tullius. At length, he excited the patricians against the king, procured his murder, and himself ascended the throne. He abolished much of the progressive legislation enacted by Servius Tullius and attempted to set up a pure despotism, but finally he was forced to flee Rome with his family because of the outrage of his son Tarquinius Sextus upon Lucretia. He died in exile at Cumae. Since much overlapping and contradiction occur in the legends dealing with the Tarquinii, it is difficult to separate truth from fiction and to determine which acts should be attributed to which king. T. R. H.

**TARRAGON** [tæ′rəgən], a bitter, aromatic perennial herb, *Artemisia dracunculus*, of the family Compositae, allied to wormwood and sagebrush. It is a native of Europe and Asia and is cultivated especially in parts of France, where the leaves are dried and used commercially to flavor tarragon vinegar and to produce oil of tarragon. It grows to about 2 ft. in height. E. R. C.

**TARRAGONA** [tɑ′rrɑgo′nɑ], the name of a province and its capital city in Catalonia, northeastern Spain.

**The City.** The city of Tarragona is a seaport on the Mediterranean Sea, about 55 mi. southwest of Barcelona. The

site was occupied in the sixth century B.C. by an Iberian people who built cyclopean walls and left many ceramic objects. Taken from the Carthaginians under Hanno by Scipio in 218 B.C., during the Second Punic War, and given the name of Tarraco, the city was highly fortified. Augustus made it the capital of the largest of the three Hispanic provinces, Hispania Tarraconensis. The Visigoths arrived in 475 under Euric and inflicted much damage. The Arabs repeated the process in 713, and their rule lasted to 1119, although the Count of Barcelona held the city temporarily in 1089. A Norman adventurer held it as a border fortress against the Arabs, and in time the local archbishop came to exercise wide political powers and to be accepted as coprimate of Spain. During the War of the Spanish Succession, Tarragona was captured by the British in 1705. It capitulated to the French in 1811 after a seven-week siege. It was among the last cities to be captured by the rebels in the Civil War of 1936 to 1939. The Archbishop of Tarragona was one of few prelates to oppose Francisco Franco's revolt against the Republic.

*THE SEMINARIO CONCILIAR OR PRIESTS' SEMINARY, BUILT ON THE TERRACED HILLSIDE AT TARRAGONA, SPAIN, WAS DECLARED A PONTIFICAL UNIVERSITY BY POPE LEO XIII IN THE LATE NINETEENTH CENTURY.*

EWING GALLOWAY

Among the Roman relics are the Aqueduct of Las Ferraras, with two levels of arches and a length of 720 ft., restored to use between 1781 and 1800; the Forum, recently excavated; a so-called Palace of Augustus; an amphitheatre; and a Roman-Christian necropolis.

In 1903 a group of monks of the Grande Chartreuse began producing their liqueur at Tarragona. The city is famous for its wines, which are exported in substantial quantities, along with fruit and other agricultural produce of the region. Manufactures include textiles (silk, cotton, and linen), alcoholic beverages, and paper. Pop. 1950, 36,807.

**The Province.** The province of Tarragona has an area of 2,426 sq. mi., much of which is mountainous, rising to elevations in excess of 4,500 ft. The rocky coast line is fairly even and has few inlets. Only in the south is it broken by the wide and marshy delta of the Ebro River. The climate is mild and rainfall averages 18 in. annually, though little falls in summer and irrigation is necessary. Only the Ebro flows the year round. Agriculture is the leading activity; cereals, wines, fruits, vegetables, and olive oil are the chief products. Textiles, leather goods, soap, paper, and processed food are manufactured. Though minerals are known to exist, they are not extensively exploited. Leading cities in the province, besides the capital, are Tortosa, Reus, and Valls. Pop. 1950, 356,864.

R. G. W.

**TARRANT CITY** [tæ′rənt], a city in Jefferson Co., in north central Alabama, about 5 mi. north of Birmingham. It is an industrial community with activities centered in coal, coke, cast-iron pipe, and Portland cement. It was incorporated as a town in 1918 and as a city in 1927. Tarrant City is governed by a mayor and council. It is served by the Louisville & Nashville Railroad. Pop. 1950, 7,571.

**TARRYTOWN,** a village in Westchester Co., in southeast New York State. It occupies high ground on the east bank of Tappan Zee, a lakelike portion of the Hudson River, in the famous Sleepy Hollow district, 24 mi. north of New York City. It is a residential community and was incorporated as a village in 1870. It is governed by a mayor and council. Tarrytown was settled by the Dutch in 1645. At the north end of the village is the André Monument near the spot where the British spy, Major John André, was captured in September 1780 en route to meet Benedict Arnold. Other historic points of interest in Tarrytown and adjoining North Tarrytown and Irvington include Washington Irving's home, Sunnyside; the former home of Jay Gould, Lyndhurst; the Old Dutch Barn with a collection of early Dutch archaeological material; Castle Philipse, built by Frederick Philipse in 1683 and now a museum; and the Old Dutch Church with the Sleepy Hollow Cemetery, in which are the graves of Washington Irving, Carl Schurz, and Robert G. Ingersoll. Tarrytown is the seat of Marymount College for women and many private schools. It is also a summer resort. Transportation is provided by the New York Central Railroad, river craft, and, in summer, a ferry to Nyack pending completion of the bridge across the Tappan Zee forming a link of the New York State Thruway. Local manufactures include automobiles and garments. Pop. 1950, 8,851.

**TARSIER** [tɑ′rsiər], a small, nocturnal, tree-living primate, sole living representative of the suborder Tarsioidea. The tarsier, *Tarsius spectrum* and related forms, is found in Sumatra, Borneo, Celebes, the southern Philippines, and in a few smaller islands. It is the size of a small squirrel, having a body about 6 in. long, and 10-in., slender, tufted tail. The hind feet are elongated, especially the ankle bones. The eyes are unusually large, the muzzle is fine and short, and the ears are broad. The fur is dense and woolly, and of a brownish, grayish color below; there is a dark rising around

IFOR THOMAS

*THE EAST INDIAN TARSIER*

the eye. The tarsier feeds on insects and other small animals. It leaps, froglike, from bough to bough, clinging to smooth branches by its large finger- and toe-pads. *See also* PRIMATES.
J. E. Hi.

**TARSUS** [tɑ′rsəs], a famous historical city in south central Turkey, in the vilayet of Içel, a few miles inland from the Mediterranean Sea and 25 mi. southwest of Adana. The Cilician Gates, a famous pass through the Toros Dağlari (Taurus Mountains) are 50 mi. north of the city. Tarsus' strategic location on a fertile plain near the pass and on the now nonexistent Cydnus River (giving it access to the sea and making it a port) aided its development but also made it a prize for invading armies. The founding of the city has been attributed to Sardanapalus, to the god Sandan, to Perseus, and to Hercules. Its first historical mention is its capture by the Assyrians. During the Persian period it flourished. During the Greek period it was the seat of a school of philosophy. When the Romans conquered the region in the first century B.C., Tarsus became the chief city of Cilicia. Augustus made it a free city and the seat of one of the three great universities of the pagan world. When it finally came under Ottoman control in the late fourteenth century, Tarsus had paid allegiance to the Byzantines, Crusaders, and every major power in the East. It is noted as the birthplace of St. Paul. Although much of the ancient city is buried beneath alluvial soil from the Cydnus, excavations have discovered artifacts dating back as far as the Stone Age. Pop. 1950, 33,822.
J. E. F.

**TARTAR.** *See* ASIATIC TRIBES (*Ural-Altaic*).

**TARTARUS** [tɑ′rtərəs], in Greek mythology, a place of punishment in the underworld. After their defeat the Titans were imprisoned in Tartarus, and there, too, were the traditional sinners Ixion, Tantalus, Sisyphus, and Tityus. *See also* UNDERWORLD.
G. E. D.

**TARTINI, GIUSEPPE** [tɑrti′ni] (1692-1770), Italian violinist, composer, and teacher, was born at Pirano, Istria, April 8, 1692. After an adventurous youth, Tartini established in Padua in 1728 a school of violin playing whose fame soon spread throughout Europe. In his school, Tartini inaugurated the use of thicker violin strings and used a bow made of lighter wood, with a less marked convex curvature. He also made studies in acoustics and the theory of music. Tartini's literary works on music are almost as numerous as his 350 musical compositions; his violin sonatas, especially the *Devil's Trill,* are frequently performed today. Tartini died at Padua, Feb. 26, 1770.
P. G. G.

**TARTU** [tɑ′rtu], formerly called by the German name Dorpat, and earlier by the Russian name Yurev, a town located in the eastern Estonian S.S.R., at 58° 25′ N. lat. and 2° 45′ E. long. It lies on both banks of the short Ema River, draining the small Lake Virts eastward into Lake Peipus (Chudskoe Ozero). Founded in 1030 by the Kiev Grand Prince Yuri or Yaroslav, it is one of the most ancient towns in the Baltic region. An Estonian castle built on the site was taken by the Teutonic Knights in 1224. In the fourteenth century it joined the Hanseatic League and achieved considerable prosperity in commerce. Taken by the Russians in 1558, it passed to Poland in 1582, to Sweden in 1600, again to Poland in 1603, and back to Sweden in 1625. During the siege of 1625 the town was partly burned. Besieged by the Russians in 1666 and 1704, it was again burned in 1708, and many inhabitants were exiled. As a result of another great conflagration in 1777, the town was rebuilt in a more modern style. Fighting in the struggle against the Bolsheviks from 1918 to 1920 brought further damage to the town. In 1920 Tartu was included in the new republic of Estonia, but it passed under Soviet control in 1940 when the country became a Soviet republic within the Soviet Union. Occupied by Nazi forces in 1941, it was liberated by Russian troops in 1944. During World War II it suffered heavy destruction, and most of the noteworthy structures received considerable damage. The Ratshof contains one of the finest picture galleries in the Baltic area. However, the chief attraction of Tartu is the university, founded in 1632 by Gustavus Adolphus and twice suppressed, but reopened in 1802. It has been a center successively of Teutonic, Russian, and Estonian culture. Tartu, the principal city of interior Estonia, has a small river port and a large timber and pulp industry. Pop. (est. 1950), 60,000.
C. C. H.

**TARTUFFE** [tɑ′rtü′f], a French five-act comedy in verse by Molière (Jean Baptiste Poquelin, 1622-1673). It was originally a three-act play, and as such was first produced at the court of Versailles in 1664. On account of its antireligious implications it was immediately forbidden. The ban was lifted by Louis XIV on Feb. 5, 1669, in a prevailing atmosphere of tolerance. Tartuffe is a religious hypocrite who speaks the language of the devout even while pursuing the most sinful and most criminal aims. The virtuous but naïve Orgon is easily taken in, and his infatuation with the impostor brings him and his family to the verge of disgrace and ruin. Molière disclaimed any intention to offend religion. Actually, he aimed at discrediting some devout people associated with the Compagnie du Saint Sacrement, who opposed the theatre in general, and Molière in particular. He was directly inspired by what he saw around him, although he borrowed from Boccaccio, Regnier, and Scarron's *L'Hypocrite,* 1662. *Tartuffe* is one of Molière's most completely realized studies of character.
H. L. B.

**TARWEED,** a name given to various species of *Madia,* heavy-scented, viscid herbs of the family Compositae growing in western America. The common tarweed of California is a variety of *M. sativa,* and is a useful forage plant for sheep pastures in dry warm soil. The showy tarweed, *M. elegans,* of California gardens, is a graceful annual, 1 to 4 ft. high, bearing yellow daisylike flowers throughout the summer.

The name is also given to *Hemizonia corymbosa,* the coast tarweed. J. C. Wis.

**TASHKENT** [tɑ′shkɛ′nt], the name of a region and its capital city in the Uzbek S.S.R. in the central southwest Soviet Union.

**The City.** Tashkent lies in a great oasis on the Chirchik River, 42 mi. above its confluence with the Syr Darya at the western end of the Kirghiz Range, about 170 mi. north of Stalinabad. Though believed to be an ancient city, Tashkent was not referred to until the seventh century. For centuries it was a focus of caravan routes and a center of trade in central Asia. Russia took the city in 1865, when the entire territory of Turkestan was added to the empire. Under the industrial expansion of the Soviet five-year plans, Tashkent became a textile-manufacturing center of importance. The completion of the Turkestan-Siberian railway in 1931 linked the city with the Trans-Siberian line and gave greater impetus to its growth. During World War II the influx of evacuées from European Russia doubled the city's population.

With the steady increase of population after the 1920's the city boundaries have been extended, and the old section with its low, mud-brick huts is confined to the southeastern area. Even in the newer districts which have concrete buildings the structures are kept low because of the numerous earthquakes occurring in the region. Tashkent has been a great cultural center of central Asia, with a state university, academy of sciences, institute of medicine, textiles institute, museum, opera house, and schools of drama, agriculture, technology, and industry. Experimental work is active in all phases of the cotton industry. Tashkent is on the Turkestan-Siberian Railway and is an important air terminal. The economic center of Soviet central Asia, the city has extensive trade in raw cotton and grain. The cotton mill, built in the 1930's, is one of the largest in Asia. Products include silk, leather goods, metalwares, tobacco products, chemicals, dressed meat, textile and agricultural machinery, steel, and flour. Pop. (est. 1954), 615,000. C. C. H.

**The Region.** Tashkent is delimited on the north by the South Kazakhstan Region, on the east by the Dzhalal-Abad and Namangan regions, on the south by the Leninabad and Ura-Tyube regions, and on the west by the Samarkand Region. The principal ethnic groups are the Uzbeks, a Turkic people of Moslem religion, but there is also a large minority of Russians settled mostly in urban communities. There are small groups of Kazakhs, Kirghizes, Tadzhiks, Armenians, and Jews. Much of the region in the Turan Lowlands is unreclaimed desert, but along the Chirchik River an extensive irrigation system has resulted in a heavy concentration of cotton, alfalfa, vegetables, and fruit (especially apricots, peaches, and grapes). Because the region is high and close to the Pamirs, it has an annual precipitation of 13 in. From a January average of 30° F., temperatures range to a July average of 80° F.; a maximum of 109° F. has been recorded. Foehn winds sweep down the valley of the Chirchik frequently during the winter months; as a result, December temperatures have at times hovered in the 80's. The region has industries, including textiles, the manufacture of cotton-cultivating machinery and trucks, and grain milling. In the vicinity of Chimkent are two electrochemical plants producing nitrogen fertilizer. Mineral resources are limited; at Almyk is a copper mine, and nearby a coal mine began to operate during World War II. Pop. (est. 1954), 1,400,000. D. L.

**TASHUNCA-UITCO** [tæshʌ′ŋkə wɪ′tko] (c. 1844-1877), popularly known as Crazy Horse, a prominent chief of the Oglala Sioux. He is said to have been given his name when a wild horse dashed through the encampment at the time of his birth. During his lifetime Crazy Horse became the most famous war leader of the southern Sioux, and was praised by Indians and whites alike as a strategist and tactician. When the Sioux went on the warpath in 1875 because of white occupancy of the Black Hills and other grievances, Crazy Horse and Sitting Bull were their leaders, the former leading the Oglala and the Cheyenne. He also participated in the Custer Massacre on the Little Big Horn. In 1876 Crazy Horse and his band surrendered to Gen. Nelson A. Miles. Suspected of stirring up another war, Crazy Horse was arrested in 1877 and shortly afterward was shot by his guards when he attempted to escape. H. T.

**TASK, THE,** by William Cowper, a poem in six books, which first appeared in 1785 and established Cowper's reputation as a poet. A friend, Lady Austen, suggested as a task the writing of a poem on the then new and fashionable article of furniture, the sofa—a circumstance that explains the title and the mock-epic opening of the poem. The remainder of the poem is a series of easy, informal essays in blank verse, containing descriptions of country life and of the landscape around Olney in various seasons, Cowper's opinions upon a vast range of subjects, including the state of society and of governments, and a thorough discussion of religious faith. S. F. F.

**TASMANIA** [tæzme′niə], a triangular-shaped island south of the eastern mainland of Australia and the smallest of the six states of the Australian Commonwealth, 26,215 sq. mi. in area, or 0.88 per cent of the total. The state includes the Macquarie Islands, 850 mi. to the southeast; King Island, about 50 mi. northwest; Hunter Island off the northwest point; the Furneaux Group off the northeast point; and Bruni Island off the southeast coast. Bass Strait, 185 mi. long, separates northern Tasmania from the south coast of Victoria; on the east coast the island is bordered by the Tasman Sea, a part of the South Pacific Ocean, and on the west and south coasts by the Indian Ocean.

**Geography.** *Topography.* Tasmania is essentially a continuation of the eastern highlands of Australia despite its separation from the mainland by the 80- to 150-mi. wide Bass Strait. Rugged mountains prevail in the west and northwest, the largest being Ben Lomond, 5,160 ft. high. These give way to a plateau 4,000 to 5,000 ft. above sea level in the center of the island. There are relatively small lowland plains in the north, east, and southwest. The principal rivers are the Tamar, in the north; the Derwent, in the central part of the island; the Gordon and Pieman, in the west; and the Arthur, in the northwest. There are many lakes in the central part of the island, including Great Lake, Lake St. Clair, Lake Sorell, and Lake Echo.

*Climate.* The climate is generally cool and moist, resembling that of New Zealand, southwest England, or the northwest coast of North America. There are, however, wide geographical variations in temperature and precipitation. In the lowlands the temperatures are moderate throughout the year, while those in the mountains and plateaus are much lower in winter. Rainfall ranges from less than 20 in. in the eastern part of the island to more than 130 in. on the west coast, which is fully exposed to the westerly storms.

**Population.** According to the census of 1947, Tasmania had a population of 257,117. About 29 per cent (76,567) of the total population lives in the state capital of Hobart. The other principal cities are Launceston, with a population of

40,449; Burnie, 7,237; and Devonport, 6,156. The population is almost entirely of British origin, the last of the pure-blooded Tasmanian aborigines having died in 1876.

**Government.** *Administration.* At the head of the administration is a governor appointed by the British Crown, who in 1950 was Admiral Sir Hugh Binney. A Legislative Council and a House of Assembly constitutes the Parliament. The Council comprises a total of 19 members who sit for a six-year period, and the House of Assembly has 30 members who are elected for five-year periods.

*Finance.* The last fiscal year (1947-1948) for which exact figures were available showed an income of £A4,815,974 and expenditures of £A5,101,882. The public debt at the same time was £A33,957,333.

**Economic Resources and Activities.** The vegetative types of Tasmania include beech forest, temperate rain forest, park lands, pine forest, moors, and alpine growth. The soils vary from rich alluvial loams and basaltic soils in parts of the lowlands to shallow, stony unproductive soils in the rougher and higher country. Resources of metallic minerals include silver, gold, tin, zinc, lead, copper, iron, and osmiridium in western Tasmania, and nonmetallic deposits of coal, limestone, clay, and oil shale in the east and north.

Apples, wheat, oats, peas, potatoes, and hay are among the chief agricultural output. In 1946-1947 the net value of agricultural and pastoral products was £A8,120,280.

For the same period the net value of manufactures was £A10,668,000, and of mining products, £A2,858,270.

**Social and Cultural Activities.** *Education.* Free and compulsory primary education in 1947 was given in 334 schools to about 34,000 children. Secondary education is provided in both state high schools and privately endowed schools, and in 1947 was given in 7 state high schools with a student enrollment of 2,240. Besides a number of technical schools, there is the University of Tasmania with 663 students in 1947, which was founded at Hobart in 1890.

*Social Services.* Pensions for old age and invalidity are paid by the Commonwealth Government, which also supports hospitals in conjunction with the state.

**History.** Tasmania was discovered Nov. 22, 1642, by the Dutch mariner Abel Janszoon Tasman, who had been sent by Anton Van Diemen, governor general of the Dutch East Indies, on an exploring expedition to Australian waters. Tasman named the region Van Diemen's Land in honor of his patron, but he was not aware of the insularity of the land he had discovered. Although Captain James Cook touched there in 1777, he likewise did not realize that Van Diemen's Land was an island. In 1798 the English explorer George Bass was provided with a whaleboat in which he made a voyage to Westernport on the mainland of Australia and satisfied himself that there was a strait between Australia and Van Diemen's Land. Later in the same year Bass and Matthew Flinders, an English mariner and hydrographer, circumnavigated the island.

*Mount Wellington above the harbor at Hobart, capital of Tasmania*

COURTESY OF THE AMERICAN MUSEUM OF NATURAL HISTORY

Settlements of the island were made in 1803 and 1804 by the English, and it became a dependency of New South Wales. Later, in 1807, a penal colony was established near the present site of Hobart. In 1825 a separation from New South Wales was brought about and Van Diemen's Land was granted a form of government like that of the parent colony. In honor of its discoverer, the name Tasmania was chosen in 1853, and three years later a system of responsible government came into being.

About this time a gold rush caused considerable emigration from Tasmania to Victoria, and an increase in exports to the same colony. Unsuccessful attempts were made to induce more people to take up land in Tasmania for agricultural purposes. The adoption of protection by Victoria only increased the difficulties of Tasmania. The discovery of tin and gold in the 1870's, together with an increased interest in agriculture and sheepraising, helped to bring the colony out of its depressed condition.

The voters of Tasmania gave strong support in the referendums on the constitution for the Australian Commonwealth in 1898 and 1899, and on Jan. 1, 1901, Tasmania was federated with the other Australian states into the Commonwealth of Australia. R. G. B. and R. V. S.

**TASMANIAN DEVIL,** a thickset, powerful marsupial, *Sarcophilus ursinus,* now restricted to Tasmania. It is the size of a large house cat and is covered with coarse black hair, but it has irregular blotches of white on the shoulders, throat,

and rump. Except for the long tail, it resembles a miniature bear in appearance. It is savage and quite untamable. The animal is destructive of other native marsupials and livestock, including sheep. It has been relentlessly hunted, and has become extinct in southern Australia. In spite of its relatively small size, the Tasmanian devil is provided with a formidable dentition and is a dangerous foe for much larger sheep dogs.

W. J. Ha.

**TASMANIAN WOLF,** largest and most formidable of living, carnivorous marsupials. The general appearance is doglike, the hind end of the body gradually tapering to the tail. The grayish-brown coat is marked with dark brown bands across the back and hindquarters. The single species, *Thylacynus cynocephalus,* is now restricted to the wilder parts of Tasmania. Formerly abundant, it has been greatly reduced by the settlers in retribution for its attacks on poultry and sheep. While the Tasmanian wolf or "tiger," as it is often called, will not attack man, it is more than a match for a dog of comparable size. It inhabits hilly, forest country, hunting in pairs during the evening. The young are carried in the pouch for 3 months, and then deposited in a den until the cubs are able to shift for themselves. W. J. Ha.

**TASSEL FLOWER,** a common garden annual, *Emilia sagittata,* of the family Compositae, also called Flora's-paintbrush. It is probably a native of the American tropics and is very easily cultivated. The erect hairy stem, 1 to 2 ft. high, bears lance-shaped leaves clasping the stem, and clusters of small scarlet flower-heads from July until frost.

J. C. Wis.

**TASSIGNY, JEAN JOSEPH MARIE GABRIEL DE LATTRE DE** [ta'si'nyi'] (1889-1952), French Resistance leader and Allied general of World War II, was born on Feb. 2, 1889, in Mouilleron-en-Pareds in Vendée, where his father was mayor. He served in World War I, which commenced a year after his graduation from the military academy at St. Cyr, and advanced from the rank of second lieutenant to that of captain. When in 1939 De Lattre became the youngest brigadier general in the French Army, he had fought under Lyautey in Morocco, had completed the staff and advanced staff courses of the Ecole Supérieure de Guerre and the Centre des Hautes Etudes Militaires in Paris, had commanded an infantry regiment, and in addition had served as General Weygand's chief of staff.

In World War II, De Lattre blocked the German offensive in Alsace until the Pétain armistice. Condemned to ten years in prison in November 1942 for his resistance to the Nazis, he escaped in September 1943. In December, De Lattre joined General Charles de Gaulle in Algiers and was made a full general and commander in chief of all French forces in North Africa. He headed the newly organized French First Army and the 36th American Division from October 1944 until May 9, 1945, the day he signed for France the documents of German surrender. In July 1945, after heading the French army of occupation and representing France on the Inter-Allied Control Commission at Berlin, he was appointed inspector general of French ground forces and in May 1948, inspector general of all French forces. In December 1950 General De Lattre was made High Commissioner and commander of French forces in Indochina, and under his leadership considerable advance was made in the fighting against the Communists. He died in Paris on Jan. 11, 1952.

M. C. C.

**TASSO, TORQUATO** [tɑ'sso; tæ'sso] (1544-1595), Italian poet of the late Renaissance, was born March 11, 1544, at Sorrento. His father, Bernardo Tasso, was a scholar and a poet, and secretary to the Prince of Salerno. In the latter city and in Naples, Torquato and his sister spent their early youth. When the boy was ten, his father went into exile with his patron, who had been condemned as a rebel against the Spanish viceroy. Soon after, Torquato left his mother, whom he was never to see again, and joined his father in order to pursue his studies. He received an excellent education, enhanced by the proximity of Renaissance court life, to which he felt peculiarly attracted. At Urbino he served as companion to the young heir to the dukedom, and at this court, Tasso became imbued with the honored ideals of the chivalric code and courteous behavior. He moved delightedly in this atmosphere of refined elegance and dreamed of spending a happy existence as the protégé of some generous and learned patron. A part of Tasso's tragedy was that he could neither completely fulfill nor wholly abandon this splendid dream.

In Venice, Torquato helped his father prepare for publication the chivalric poem, *Amadigi,* on which Bernardo had worked for years, and began to turn over in his mind epic subjects which he himself might treat. But Bernardo sent him to study law at Padua, where he came under the influence of Scipione Gonzaga, Sperone Speroni, and Carlo Sigonio, and acquired a taste for philosophy and critical theory. Here also he began to publish lyric verse and composed a romantic narrative poem, *Rinaldo,* which was printed in 1562, when Tasso was only eighteen years old. In 1565 he went to Ferrara and entered the service of Cardinal Luigi d'Este, brother

TORQUATO TASSO

CULVER SERVICE

of Duke Alfonso II. He plunged with delight into the splendid life of the gay little capital. After a brief journey to Paris in 1570-1571 in the retinue of Luigi, he entered the service of Duke Alfonso himself, as court poet. Admired, pampered, envied by those about him, pleased with his new independence and the freedom to develop his natural talents, Tasso now spent several happy years, the last that he was to know. He wrote amorous lyrics to various ladies of the court. He composed, in a few weeks and with little effort, the five acts of his *Aminta,* a pastoral drama or woodland fable. The play, one of the best of its kind, was performed in 1573 before the court. While still sustained by the exaltation of this success and the increasing recognition of his poetic genius, Tasso completed, in 1575, the composition of his masterwork, the noble and harmonious epic poem, *Gerusalemme Liberata* ("Jerusalem Delivered"). These labors seem to have had a deleterious effect on the nerves and mind of the over-sensitive poet. He developed an abnormal sus-

ceptibility to criticism; he suffered from excessive religious scruples; he came to believe that he was being persecuted by envious courtiers. After several violent outbreaks of temper he was confined in 1579 as a madman in the prison of Sant'Anna in Ferrara, where he spent seven wretched years. This circumstance soon gave rise to a legend which attributed the cause of his misfortunes to a mad passion for Leonora d'Este, the Duke's sister, and to the Duke's desire for revenge. This legend lent added pathos to the figure of the unfortunate poet, who became a symbol of misunderstood genius and furnished a subject for many romantic works of art and literature.

During his incarceration Tasso continued, in his lucid moments, to write lyric poems and treatises in dialogue form on literary and philosophical subjects. His *Aminta* and *Gerusalemme liberata* were published in 1581, without his authorization, and gained immediate popularity. *Gerusalemme liberata* aroused long and bitter discussions among the critics, who disapproved of Tasso's attempt to reconcile Ariosto and Virgil in his conception of the heroic poem.

Tasso was finally liberated in 1586. During the remaining nine years of his life he appeared as a pathetic figure, wandering restlessly throughout Italy, his health broken, his genius spent. He found temporary refuge with various protectors, whom he celebrated in verse, including G. B. Manso, who was to write his first biography, and Cardinals Pietro and Cintio Aldobrandini, to whom he dedicated his *Gerusalemme conquistata,* a tiresome reworking of the *Gerusalemme liberata.* Pope Clement VIII finally granted him a pension, promising to confer upon him the laurel crown. But the ceremony was repeatedly postponed, and death robbed the unhappy poet of this last honor. He died on April 25, 1595, in the monastery of Sant' Onofrio in Rome and was buried in the chapel there. His grave was destined to become a place of pilgrimage for many generations of admirers.

Tasso's complete works fill several large volumes and include, besides those already mentioned, innumerable sonnets, many of which are excellent, numerous letters, a tragedy, *Torrismondo,* a poem on the creation of the world entitled *Le Sette giornate,* smaller poems of unequal worth, and the important *Discorsi dell' arte poetica.*

Tasso was a poet astride two ages. His tastes and aspirations were those of the high Italian Renaissance before the Council of Trent; but he lived his mature years during the Counter-Reformation. However, he made a serious effort to conform and to become the poet of his era. A sincere Christian strain may be traced throughout his work, but it does not go deep. It produces at most a general religious coloring and a few heartfelt accents. There is nothing of the mystic or the Puritan in Tasso, and he was rather the victim than the typical singer of his age. The deepest note in his poetry is not religious, but passionate and lyrical. The conflict between his temperament and his times, as well as between his dreams and the harsh realities of his experience, left its mark on his whole life and work, and accounts for most of the shortcomings of the poet and the tragic appeal of the man. *See also* Aminta; Gerusalemme Liberata. C. B. B.

**TASTE.** *See* Comparative Anatomy; Mammal (*Nervous System*); Sensation.

**TATAR.** *See* Asiatic Tribes (*Ural-Altaic*).

**TATAR AUTONOMOUS SOVIET SOCIALIST REPUBLIC** [tɑ′tər], a territorial-political unit of the west central Russian Soviet Federated Socialist Republic of the Soviet Union. Its area of 25,900 sq. mi. is bounded on the north by the Mari and Udmurt Autonomous Soviet Socialist Republics and the Kirov Region; on the east by the Bashkir Autonomous Soviet Socialist Republic; on the south by the Chkalov, Kuibyshev, and Ulyanovsk regions; and on the west by the Chuvash Autonomous Soviet Socialist Republic. The principal ethnic groups of the republic, which was established in 1922, are Tatars (50.5 per cent, predominantly rural) and Russians (42 per cent, urban). The Tatars are Moslems of Turco-Tatar stock. Culturally they are considered the most advanced Moslem nationality in the Soviet Union. Kazan, the capital, is the center of Tatar cultural life.

Poor podsols and sandy soils are found in the republic, except in the southwest, where fertile black soils occur. The climate is one of continental extremes and an undependable rainfall of about 15 in. annually. Despite these handicaps the republic is predominantly agricultural. There are important acreages of spring wheat, winter rye, buckwheat, peas, chicory, potatoes, and sunflowers. The agriculture has been collectivized almost completely. In industry the Tatar Republic leads the Soviet Union in the processing of furs. Also significant are the production of soap and candles, and the manufacture of felt boots, asphalt, and typewriters. Pop. (est. 1954), 3,200,000. D. L.

**TATE.** *See* Asiatic Tribes (*Indo-Iranian*).

**TATE, ALLEN** (1899- ), American critic and poet, was born in Clark County, Ky., Nov. 19, 1899. He graduated from Vanderbilt University in 1922, and, as a teacher, has been associated with several colleges, notably as Fellow in Creative Writing at Princeton, 1939-1942. In 1944 he became professor of English at the University of the South and editor of the *Sewanee Review.* Tate's sectionalism is demonstrated in *Stonewall Jackson—The Good Soldier* (1928), *Jefferson Davis—His Rise and Fall* (1929), his novel *The Fathers* (1938), and his essays for the Agrarians. His verse, influenced by John Donne and T. S. Eliot, is represented in *Poems, 1920-1945* (1946). *Reactionary Essays in Poetry and Ideas* (1936) and *Reason in Madness* (1941) illustrate his antihistorical method of literary criticism. G. C. K.

**TATUNG** [dɑ′tʊ′ŋ], a railway town in the northern part of Shansi Province in east central China, situated on the west bank of the Yu Ho, at the junction of the Peiping-Suiyuan (Peiping to Paotow) and the Tung-Pu (from Tatung to Fenglingtu) railways. The town is built on a level plain 3,445 ft. above sea level, with the Heng Shan rising to the south and a spur of the Yin Shan range in the north. Tatung was the capital of the Northern Wei dynasty for the period A.D. 386-493. For the Liao (Khitan) Dynasty (A.D. 907-1154) and the Chin (Golden) Dynasty (A.D. 1115-1234), Tatung was their Western Capital. During the Ch'ing (Manchu) Dynasty (A.D. 1644-1912), when the town was known as Tatungfu, it was the site of a prefectural government. Tatung is a trading point, importing sheep, camels, fur, skins, and wool from Inner Mongolia and exporting tea, silk, cotton piece goods, and the rich agricultural products from the Fen River Valley (in Shansi Province) to Mongolia. However,

Tatung is primarily important as a coal center. To the southeast of Tatung, at Kowchuan, lies a coal reserve estimated at 40,000,000 tons of high quality coal. Glass manufacturing is an ancient industry of the town, dating back to the days of the Northern Wei Dynasty. The art of glass making was later perfected by Persian artisans who found their way to this part of China at the beginning of the fifth century. Pop. (est.), 50,000. A. C. T.

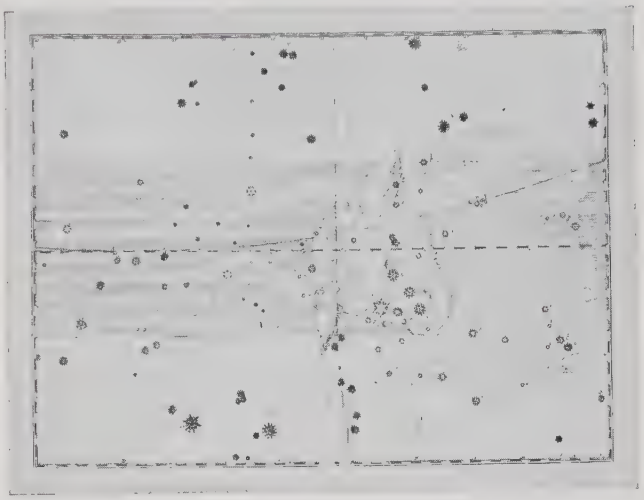
**TAUERN** [tau′ərn], a mountain range lying east of the Brenner Pass in the central Austrian Alps. The Hohe Tauern consists of granite gneiss rock and contains Gross Glockner, 12,457 ft., Austria's highest peak, as well as several other mountains above 12,000 ft. With a length of 83 mi. and a width of 30 mi., it is crossed via the Tauern Tunnel by a railway linking Salzburg and Carinthia. To the north is the Salzach River, flowing into the Inn, and to the south, the Drau flowing into Yugoslavia, where it is called the Drava, and finally into the Danube (Dunav). The snow line exists at from 9,000 to 9,500 ft. elevation. The region is a noted tourist center and many famous hotels are located here.

The Niedere Tauern, east of the Hohe Tauern, lies between the Enns and the Mürz river systems and is crossed by the Radstädter Tauern Pass (5,700 ft.) linking Salzburg with southeastern Austria. The region is a noted sports center and contains several peaks exceeding 9,000 ft. in height, including Hochgolling, 9,392 ft., and Hohe Wildstelle, 9,010 ft. S. Van V.

**TAUNTON** [tɑ′ntən; tɔ′ntən], a municipal and parliamentary borough, the county town of Somersetshire, England, in the Tone River Valley, 130 mi. southwest of London. It is a market town for the surrounding district, known as Taunton Deane, famous for apples and cider. Woolen textiles, leather goods, and plastics are manufactured, but farming is an important occupation. Coins dug up in the seventeenth century indicate a Roman settlement there. In Saxon times Taunton was of some importance. A Saxon king built a castle in Taunton which was later demolished. The community received a charter of incorporation in 1627 from Charles I, but this charter was taken away by Charles II in 1660, the year in which the town's walls were destroyed. In 1677 Charles II issued another charter reincorporating Taunton. Of the twelfth-century castle dismantled during the Restoration, enough remains to house a museum. Norman and early English features are distinguishable in the parish church, and among other antiquities are a notable market cross and the scant remains of a priory founded in the reign of Henry I. Pop. 1952, 34,600. A. W.

**TAUNTON,** a city in southeastern Massachusetts, the county seat of Bristol Co., situated on the Taunton River, at the head of ocean navigation, 36 mi. south of Boston. Taunton was settled by colonists from the Massachusetts Bay Colony and first known as Cohannet, but it was renamed later in honor of Taunton, England. It was incorporated as a town in 1639 and as a city in 1864. When the Boston Port Act was passed in 1774, the people of Taunton, led by Robert Treat Paine, a signer of the Declaration of Independence, showed their sympathy for Boston by hoisting on the village green the British "Red Meteor" flag bearing the words "Liberty and Union." Reed and Barton established their silverware business in Taunton in 1824; the Rogers Silverware Company was incorporated in 1883; and Isaac Babbitt, inventor of "Babbitt metal," produced Britannia ware in Taunton. The city is the seat of a state hospital for the insane. The New York, New Haven and Hartford Railroad serves the community. Principal manufactures include silverware, textiles, textile machinery, stove linings, crucibles, and bricks. Pop. 1950, 40,109.

**TAURUS** [tɔ′rəs], the Bull, a large ancient constellation, located immediately north of the celestial equator, and with its center in right ascension at about 4 hr. 30 min. Its symbol ♉ is the second sign of the zodiac, which the sun enters on April 20. Within its boundaries are the Pleiades



COURTESY OF THE AMERICAN MUSEUM OF NATURAL HISTORY

*TAURUS, THE BULL*

and the Hyades. The latter is a V-shaped figure of stars, all of which are faint with the exception of Aldebaran, at the upper part of the left branch. When in the west, the V stands upright. In constellation figures, the Pleiades are in the shoulder of the Bull with the Hyades in his face. Aldebaran represents his eye. As is usual with animal constellations, only the front half of the Bull is depicted by stars. Taurus is rich in telescopic double stars. About 1° north of the star Zeta is the noted Crab nebula. Chinese records indicate that a brilliant nova appeared in this general location in A.D. 1054, and the nebula is expanding at a rate which would place its beginning at about that date.

In mythology, Taurus was the snow-white bull which carried Europa to Crete. The Pleiades were seven sisters, daughters of Atlas; the Hyades, their half sisters. *See also* ALDEBARAN; PLEIADES. J. H. P.

**TAURUS,** a range of mountains in southern Turkey that extends in an east-west direction parallel to the Mediterranean sea coast. The mountains are folded ranges, arranged in echelon, and the maximum elevations are between 10,000 and 11,000 ft. These mountains form a spectacularly beautiful wall that cuts off the Anatolian Plateau from the Mediterranean Sea; and drowned spurs of the Taurus form some of the islands of the Aegean Sea. In the east the mountains bend to a northeast-southwest direction and eventually join the Armenian Knot. The Taurus Range is paralleled in the east by the Anti-Taurus Range. J. E. F.

**TAUSSIG, FRANK WILLIAM** [tau′sɪg] (1859-1940), American economist, was born at St. Louis, Mo., Dec. 28, 1859. He was educated in the local schools, attended Washington University in St. Louis, graduated from Harvard University (1879) and studied at the University of Berlin.

He was appointed an instructor in economics at Harvard University in 1882, becoming professor of political economy in 1892, Henry Lee Professor in 1901 and Henry Lee Professor Emeritus in 1935. He was editor of the *Quarterly Journal of Economics* from 1896 to 1937. He concentrated his attention on finance and the tariff, was president of the American Economic Association in 1904-1905 and helped organize the Harvard Graduate School of Business Administration, 1906-1907. Taussig was chairman of the United States Tariff Commission in 1917-1919, a delegate to the Paris Peace Conference in 1919, a member of the President's Industrial Conference in 1919-1920, and a member of the Sugar Equalization Board from 1919 to 1926. He was the author of *The Tariff History of the United States* (1888), *Wages and Capital* (1896), *Principles of Economics* (1911), and other similar books and articles on economics and finance. Taussig died at Cambridge, Mass., Nov. 11, 1940. T. R. H.

**TAWACONI.** *See* Indian Tribes, North American (*Southeast*).

**TAXATION,** the act of raising revenues by levying charges against persons and property; the method of determining and making such charges for the support of government; and the amounts levied, which are known as taxes. A tax is a compulsory contribution from the wealth of a person or body of persons for the service of the public powers. There are three important elements in this definition. First, tax payment is compulsory. The power to tax is an attribute of sovereignty and hence is not to be neglected or ignored by the persons subject thereto. Second, taxes are paid by individuals. They may be levied on property or on objects animate or inanimate, but the obligation to pay is always upon a person or upon a body of persons such as a corporation. Third, taxes are collected for the service of the public powers, which means the support of the services and activities undertaken by government.

## DEVELOPMENT OF TAXATION

**Ancient Collection Methods.** Some method or other whereby the constituted public authorities have drawn for their support upon the resources of the people has existed since the beginnings of organized government. One of the earliest manifestations of the division of labor was that between the governors and the governed. The duty of the governed was to obey orders and to supply the governors with the means of their support. The manner in which the people have supported the government has varied in different historical epochs and with changing economic conditions. In ancient times, the contributions were largely in kind. The priesthood, which emerged as the first governing body of the Hebrews after the escape from Egypt, was supported by a tithing system under which a percentage—usually a tenth—of the increase of the flocks and herds was given. Under the monarchy that supplanted the priesthood in the administration of secular affairs, public revenues were collected both in kind and in money. The drain upon the people's resources had become so heavy by the end of King Solomon's reign as to lead to protests and pleas for relief when Rehoboam succeeded to the throne. The appeals were dismissed and still heavier exactions were threatened.

Studies of Egypt under Roman rule reveal an array of taxes similar to the multiplicity of taxes in modern times. Levies included a land tax, collected in kind from grain land and in money from vine and garden land; poll taxes; taxes on animals, trades, industries, and fishing, and on sales of various goods; and import and export duties. The use of money for taxes in the time of Christ is indicated by His answer to the question whether or not it was lawful to give tribute to Caesar. The answer was: "Render under Caesar the things that are Caesar's," that is, the money bearing his image and superscription (Mark xii: 17).

**Growth of Money Economy.** After the decay of the Roman Empire, Europe passed into the long decline of the Dark Ages. This was a period of strife among the many small states and principalities which were the fragments of the empire. Taxation as such ceased to be a major source of governmental support, and, instead, the concept of feudalism evolved.

The growth of a price and market system as a money economy expanded led to the collection of a greater proportion of the public revenues in money rather than in kind. Even so, there was relatively little use of taxation to obtain the money for public use except in England, where feudalism decayed earliest and most completely. It is significant of the slow economic development of continental Europe that as late as the third quarter of the eighteenth century the leading cameralist writers of the time could still give first place, as a source of public support, to the revenues from the crown domains, with the regalian, or royal privilege, revenues second and taxation third. By this time, also, the doctrine of mercantilism had degenerated into the concept that money, as such, is the most important form of wealth.

In 1776, Adam Smith, however, attacked the old economic systems and ideas in his book *An Inquiry into the Nature and Causes of the Wealth of Nations.* He completely demolished the reasoning which supported the then-current policy of state control and planning, and the notion that government, through its acts and decisions, could increase the wealth of the nation. He demonstrated that the wealth and strength of a nation rest upon the wealth and economic capacity of the citizens. He may have been familiar with Colbert's famous phrase, *"Il faut laisser faire les hommes,"* although the expression *laisser* (*laissez*) *faire* does not occur in his book. But he demonstrated that the state should leave its citizens free to seek their economic advantage wherever and however, in lawful ways, the prospect of gain might lead them, at home or abroad. The state whose citizens are wealthy and prosperous is a strong state. Such a state is strong because it can draw upon the wealth and income of its citizens through taxation to meet the public needs. Smith reversed the counsel of the cameralists by putting taxation first instead of last in the sources of public revenue. He advised sale of the sovereign's domain and use of the proceeds to redeem the public debt. This viewpoint may have influenced the early policy followed by the United States Government with respect to the public lands and the national debt.

Smith's theories pointed to the conclusion that the state should leave its citizens as free as possible to gain wealth and income, and that it should derive its own support from taxes levied on the incomes and wealth of the people. But it must not be inferred that this advice pointed to reckless, punitive, discriminatory, or wasteful taxation. Smith laid down certain maxims or canons of taxation which he believed should guide the state in its exercise of the taxing power. These may be characterized as, equality, certainty, convenience, and economy.

In brief, these maxims mean that there must be equality in the distribution of the tax burden; that the amount each person is to pay should be certain and definite; that the time

and manner of payment should be as convenient for the taxpayer as possible; and that the administrative costs should be held down to the minimum.

**Tax Reforms in the French Revolution.** Taxation under the old regime was one of the many causes of the unrest which produced the French Revolution. It was one of the subjects of thoroughgoing reform and revision when the blood purge ended and the Assembly settled down to constructive business. The new taxes, which were destined to form the framework of the French revenue system until the financial strain of World War I compelled a change, were established on certain broad principles that may be summarized as follows:

(1) Objectivity. This means that the tax base must be one capable of objective determination, as by measuring, weighing, or counting, so that neither the personality, nor the social standing, nor the private personal affairs of the taxpayer need be considered in the assessment, levy, and collection of the tax.

(2) Proportionality. This principle was a direct outgrowth of the revolutionary slogan of equality. To the revolutionists, it meant that the rich should pay the same rate of tax as the poor.

(3) Definiteness. This principle was aimed, as was Smith's maxim of certainty, at the vicious practice of "tax farming." Under this practice, tax collections were farmed out as concessions. The concessionaire paid a fixed sum to the treasury and kept all that could be extorted above the contract payment. This extortion, or squeezing, was done efficiently and hence was lucrative. The Assembly ended this practice by setting, particularly for the land tax, fixed quotas to be collected, and allocating to each governmental subdivision its share of the total.

**English Revolt Against Arbitrary Power.** A substantial contribution to taxation theory and practice, apart from the influence of Adam Smith, was made by English experience. In one particularly important aspect, namely the constitutional side of taxation, the developments in England were of paramount significance. The patrimony of the state includes not only its natural resources of land, water, minerals, and so on, but also the productive capacity of the citizens. The early resistance of the English people to the efforts of the vested ruling interests to levy at will upon the product of their work was one of the steps in the evolution of the taxing power.

*Magna Carta.* Such rudimentary elements of a democratic system as the Saxons may have developed in England were supplanted, after the Norman conquest, by a feudal system on the European model. The successors of William I extended and increased their exactions and also their claims to autocratic power until, in 1215, a showdown came at Runnymede, where King John was forced to sign the first great charter (Magna Carta) defining the rights of Englishmen. This great charter contained some restrictions on the king's power to impose the thirteenth century equivalent of taxes. These were stated as follows: "No scutage or aid shall be imposed in our Kingdom except by the common council of our Kingdom, except for the ransoming of our body, for the making our oldest son a knight, and for once marrying our oldest daughter, and for these purposes it shall be only a reasonable aid."

*Bill of Rights.* The next great landmark in the evolution of the principle that sovereignty, and hence the taxing power, resides in the people, not in the ruler, came in the Bill of Rights of 1689. The following passage relates to taxation: " . . . levying money to or for the use of the Crown by pretense of prerogative without grant of Parliament for longer time or in other manner than the same is or shall be granted, is illegal."

The Bill of Rights did not establish Parliamentary control over all aspects of the public finances. Thus, it did not provide for control of spending or of public debt. Even in modern times the people have been deprived of their constitutional right of control over the public purse by inordinate spending financed by increasing the public debt. In practice, therefore, the limitation quoted above was not too effective immediately in keeping down governmental costs. But it did put an end, once and for all, to such unwise measures as King Charles I had undertaken: namely, to decree and levy taxes without Parliamentary consent. It gave full authority to the evolving concept that the people, through Parliament, had the power to pass upon tax levies. Thus was completed the first stage in the evolution of constitutional government. The core of this evolution is determination of the locus of the power to tax. Where that power resides, there resides sovereignty.

**Tax Provisions of the United States Constitution.** This record should make it easier to understand why English colonists in America nearly a century later, should resent taxes levied upon them by a Parliament in which they were not represented. They knew that there had been a revolution in 1688 in which the last weak remnant of the Stuart family had been dethroned, and out of which had come the Bill of Rights, applicable to all Englishmen everywhere. When the Constitution of the United States was written, the promise that the sovereign power, in all its aspects, was in the people was accepted as a matter of course. The provisions relating to taxation are:

Art. I, Sec. viii, par. 1: "The Congress shall have power to lay and collect taxes, duties, imposts, and excises, to pay the debts and provide for the common defense and general welfare of the United States; but all duties, imposts, and excises shall be uniform throughout the United States."

Art. I, Sec. ix, par. 4: "No capitation or other direct tax shall be laid unless in proportion to the census or enumeration herein before directed to be taken."

Art. I, Sec. ix, par. 5: "No tax or duty shall be laid on articles exported from any state."

Art. I, Sec. x, par. 2: "No state shall, without the consent of the Congress, lay any imposts or duties on imports or exports, except what may be absolutely necessary for executing its inspection laws; and the net produce of all duties and imposts, laid by any state on imports or exports, shall be for the use of the Treasury of the United States; and all such laws shall be subject to the revision and control of the Congress."

In the process of judicial interpretation, various other provisions of the Constitution have been held applicable to taxation, although their original intent may have been otherwise. For example, the states may not burden interstate commerce by taxation. No state may, by taxation, contravene the provisions of federal treaties. Neither federal nor state governments may, by taxation, interfere with the essential operations of the other. To make the popular control over the purse more secure, it was provided that bills for raising revenue must originate in the House of Representatives, which was then expected to be more closely and directly representative of the people than the Senate.

**Tax Jurisdiction.** One of the most difficult questions in taxation is the determination of what persons or what things a government has the right to tax. One answer would be that this right extends to all persons or things within its

jurisdiction, but there still remains the problem of the circumstances that indicate whether the person or the object sought to be taxed is within the jurisdiction.

*Real Property.* The historic rule with respect to "things" was that real property was taxed where situated, while personal or movable property was taxed at the domicile of the owner. Many classes of tangible personal property, such as merchandise, livestock, and tools are taxed where located, regardless of the owner's domicile. Even intangible property, such as bonds, stocks, mortgage notes, and bank credits may be taxed at situs if it can be established that they are held there for purposes connected with business operations.

*Income.* Income presents a problem because it may originate in one jurisdiction while the recipient may live in another. Each government would have a legitimate claim, but if both exercised it there would be double taxation of that particular income. The solution is to establish, as a uniform procedure, either the rule of situs or that of domicile. Under the former, a government would tax all income originating within its jurisdiction, regardless of where the owner lived. Under the latter, a government would tax its residents on their income from all sources, and would not tax nonresidents at all. The compromise solution that has been most generally reached is to tax nonresidents on the income received within the taxing jurisdiction, but with reciprocal provisions either for exemption or for an appropriate tax credit on account of the taxes paid to the jurisdiction of residence.

*Inheritance.* In the case of the death taxes, the problem has become particularly acute in the United States because of Supreme Court rulings that a person may have more than one domicile. The states have been quick to seize upon this judicial viewpoint to levy double or multiple inheritance taxes upon large estates.

## DISTRIBUTION OF THE TAX BURDEN

No fixed rule can be given for the distribution of the tax burden among the citizens. Since the power to tax is vested in the people, it is reasonable to say that they incline to equality of taxation as a standard. In a democratic society there is general emphasis upon equality, expressed in such terms as the equal protection of the laws, equality of such privileges as the use of the public highways and public schools, equal voting rights, and so on. It is logical to set against this equality of protection and privileges an equality of responsibility for the support of government through taxation. On this premise, the difficulty is to find a practical test or standard of equality. The two principal solutions that have been developed are: (1) taxation according to benefit, and (2) taxation according to ability.

**Taxation According to Benefits Received.** According to the benefit standard, the citizens would contribute to governmental costs in relation to the benefits which they respectively received. Some payments are made on this basis. Examples are the special assessment, which is levied to defray the costs of improvements that benefit property; the charges made by the Post Office, the registrar of deeds, and the various licensing bureaus; and also the tolls paid for using special public facilities such as tunnels, bridges, and express highways. A certain part of the governmental expense can be covered by charges against the persons benefited, but there are other elements of this expense which involve common or general benefit rather than specific, measurable benefit to particular individuals.

**Taxation According to Ability.** The first strong impetus toward ability as a standard of equality was given by Adam Smith, who used the term in the first of his maxims on taxation. On this he wrote in part as follows: "The subjects of every state ought to contribute towards the support of the government, as nearly as possible, in proportion to their respective abilities; that is, in proportion to the revenue which they respectively enjoy under the protection of the state. . . . In the observance or neglect of this maxim consists what is called the equality of taxation."

According to this view, equality of taxation is attained when the citizens are contributing to the support of government in proportion to their respective abilities. Neither ability nor revenue is defined, but it is clear that Smith thought of a direct proportional relationship between them. That is, ability is a direct, proportional function of revenue. It is altogether probable that revenue meant, to Smith, the total income of the individual. There is nothing to indicate that he had in mind the "individual net income" of modern tax laws.

Application of the simple test of equality suggested in Smith's first maxim would be possible only by collecting all tax revenue through a single levy on incomes. This was not done, even in Smith's time. It would be quite impractical today, in view of the immense sums needed, despite the economic fact that all taxes, however imposed, are paid out of income. It has turned out, therefore, that the concept of ability has had little attention except in connection with the income tax.

A consequence of the overemphasis upon ability in the taxation of income is that it has led to a nearly universal belief that the rates of this tax must be steeply graduated or progressive in order to constitute an application of the ability principle. It is clear that the amount of ability that anyone has, in the sense under consideration, depends upon the amount of his income. A person with $4,000 of income a year has double the ability of another person with an annual income of $2,000. This is obviously true since each dollar of income can be spent only once. There is no multiplier that enables the recipient of a large income to spend the same dollars several times and still have them. The ability to buy anything, to pay rent or doctor's bills, to spend for any other purpose, or to pay taxes, is strictly proportional to income. Opposed to this viewpoint is one which says that ability increases faster than income. It says that the person with $12,000 income a year has more than six times the ability of one with $2,000 income a year, although he has only six times as many dollars of income in the same period.

One of the arguments advanced by advocates of progressive taxation is that enough is left out of the middle and larger incomes, even after payment of drastic progressive taxes, to meet the reasonable consumption requirements of the recipients. Proponents of a strictly proportional plan have answered this "cost of living" argument by declaring that there is another highly important function of income, which is the creation of more and better capital through saving and investment.

It must be emphasized that, apart from a philosophical search for a general principle such as equality, the particular manner in which a given state or nation may decide to apportion its tax load among its citizens is a matter of policy to be determined according to circumstances and conditions. For example, some of the states of the United States have consistently refused to introduce a state income tax. In others, an income tax would be quite unproductive. Some states limit the property tax to real estate; others tax both personal and real property. It is conceded that there is no one absolute standard by which to prescribe what and whom to tax. It is

also generally recognized that the one important thing to watch is the effect of the taxes selected upon the long-run prosperity of the people.

**Double Taxation.** Another aspect of the distribution of the tax burden is presented by double taxation. The term is most commonly used to mean the taxation of the same object by two co-ordinate jurisdictions, such as two states or two national governments. It can also mean taxation of the same object twice, or in two ways, by the same government. Taxation of the same object, such as property or income, by federal and state governments, or by a state and its cities, is not regarded as double taxation in the objectionable sense, for it is realized that all levels of government must draw their support from the same body of taxpayers.

The principal objections to double taxation are: first, that it is discriminatory, since the double burden is not spread among all, but only among those who happen to be caught in certain circumstances; and, second, that it imposes a heavier burden upon some than upon others because of the lack of universality. The problem is best dealt with by reciprocal arrangements under which some agreed basis for determining tax liability is accepted, such as residence in the case of the income tax. Tax agreements between the United States and other countries have ironed out many of the difficulties at the national level. Reciprocity and, in the case of business taxes, acceptance of a standard formula for allocating business income among the states have proved satisfactory measures at the state level. The federal law permits deduction of state taxes on income in determining taxable income. A conspicuous case of a government taxing the same thing twice is the federal rule requiring taxation of dividend income to shareholders in addition to the tax paid by the corporations on net income.

## SHIFTING AND INCIDENCE OF TAXATION

**General Economics of Exchanges.** It has long been understood that a tax which is imposed at one point may be transferred elsewhere. The transfer of the tax is called shifting and its coming to rest at some other point is called incidence. Both terms are needed to complete the concept, for there must be an eventual place where the burden is borne if there is a transfer or shift away from the point of original levy.

The transfer of a tax by the one who first pays it to someone else involves some kind of economic transaction between the two parties. Hence the economics of tax shifting lead into the field of exchange and price. The original taxpayer must be in a position to effect some kind of price adjustment, including wages as one form of price, in order to transfer the burden of the tax to another taxpayer. The manner of this transfer will be determined, usually, by the line of least resistance. A retail merchant, for example, may pass his tax on merchandise along to consumers by charging higher prices, or back to the wholesaler by insisting on reduced wholesale prices, or to his employees by wage reductions. The actual shifting of a tax is not as simple as this illustration may imply. The other party to the transaction always has his freedom of action also. The consumer may resist the higher prices, or the wholesaler may refuse to quote lower prices, or the workers may not accept the wage cut. A condition essential to tax shifting is that the imposition of the tax must introduce new circumstances under which price adjustments not theretofore possible have been made possible. Otherwise, the question arises as to why the merchant should delay increasing his prices until a tax is imposed, or until it has been increased. The answer must be that the introduction of the tax, or of a tax increase, has so changed the market situation as to open the way for tax shifting.

*Monopoly.* There are many who believe that a monopolist has no trouble whatever in shifting his taxes. It is true that he has control over the supply and can raise or lower it at will. But he does not have control over the prices that buyers will pay, or over the amount that they will buy.

*Competition.* Under competitive conditions no single producer or set of producers has control of the total supply. Each producer has his own costs of production, and there may be considerable variation. The market price for a commodity that is produced under such conditions may be a composite of all of the various cost factors. In a situation of this sort, and it is fairly typical of production conditions, the question arises of how it would be possible for a tax imposed upon producers to be shifted by them to the consumers. Perhaps the showing of a loss should be the signal for a prompt withdrawal from the unprofitable line, or for diversion into some more promising line.

In general, the conclusion appears reasonable that tax shifting does not occur easily and automatically. It has to come the hard way. In the long run, if taxes are so heavy as to prevent further capital investment, production will decline and prices will rise.

**Shifting of Particular Taxes.** Some specific applications of the general theory of tax shifting may be made in the case of certain important types of tax.

*Property Tax.* It is necessary to distinguish between real and personal property. Real property includes land and the permanent improvements thereon, such as buildings. Personal property includes movables, both tangible and intangible. The usual practice in administering the property tax is to make separate assessments of real and personal property, and also to list and value separately lands and structures.

According to orthodox theory, that part of the property tax which falls on the land is not shifted. It is assumed that the landlord is already getting a rent equal to the full economic value of the site and any effort on his part to increase the ground rent would depress the tenant's return to a point at which he would be forced to abandon his lease by recourse to bankruptcy if by no other means. The particular site would then be unused. On this assumption, any tax levied must come out of the owner's return. The tenant cannot afford to pay more.

The case of buildings is different because in the long run investment can be diverted from this field if the return is inadequate. But, because of the long life span of most structures, the ability of owners to shift tax currently depends on the demand and supply situation. Where housing demand exceeds supply, and assuming that there are no rent controls, owners can obtain rents that will provide adequate, even an excessive return on the investment, plus taxes. Where housing supply exceeds demand, as in a declining mill or mining town, owners must make concessions to get tenants, and there can be no question about who bears the burden of the tax.

*Income Tax.* The tax on individual incomes is very likely to stay where it is levied, for the reason that there is little opportunity for subsequent economic transactions by which the tax can be passed on. Stockholders cannot compel corporations to pay larger dividends because of the income tax, and bondholders cannot change the terms of bond contracts merely because they must pay a tax. Again, it must be pointed out that, in the final analysis, stocks and bonds will not find a market unless the income return, after taxes, appears adequate. But, on a year-by-year basis, there is not much

that investors can do about recovering income taxes on dividends and interest. Substantially the same conclusion applies to wage and salary incomes, which are ordinarily determined by the ability and productiveness of the employees. Tightly organized labor groups are able to force wage concessions almost at will, but their demands are not timed with, nor are they necessarily related in any other manner to, tax changes.

With respect to business income, it should be pointed out that a tax on profits or net income has no impact except on the firms that are making money inside the price margin, and that such a tax can therefore have no effect upon the total volume of production at a given time. While there may be exceptions as to particular leaders in specific industries, the general conclusion would be that a tax on business income is not shifted, except as this result would follow from the long-run operation of changes in the flow of capital into industry.

*Sales Taxes.* The general practice under sales tax laws in the United States is to require the seller to bill the tax to the customer as a charge which is separate and distinct from the price of the article bought. This rule has been devised to prevent any unfair advantage from being gained by merchants who sought customers by advertising that they were absorbing the tax when, in fact, such might not be the case. In view of the established tax billing procedure, there is a good *prima facie* case that the customers are bearing the burden. Numerous exceptions probably exist, however, since every merchant is free to adopt a pricing policy that he deems will best further his own interests.

## TAX CAPITALIZATION

The capitalization of a tax is a corollary of the well-known principle of determining capital value by the process of capitalizing the annual income of an asset at some assumed rate of interest. Since the tax constitutes a deduction from the annual income, its effect on the capital value can be ascertained by a parallel capitalization.

Capitalization of taxes can be illustrated as follows, disregarding various technical qualifications: If the going rate of interest on long-term well-secured bonds is 3 per cent, a bond bearing a coupon rate of 3 per cent will sell at par. The income return from a $1,000 bond will be $30 a year, which will be 3 per cent on the investment. If a tax of 1 per cent of the value is imposed on such a bond, the levy, amounting to $10 a year, will reduce the income from the bond to $20. If the owner of the bond offered it for sale after the imposition of the tax, and if the prospective buyer wanted a 3 per cent return on his investment, he would obviously pay only that sum on which $20 would represent a return of 3 per cent, namely $666.66. He would get the same result by capitalizing the $10 tax at 3 per cent, which would be $333.33, and deducting this from the former price of $1,000.

This simplified illustration assumes that there will be an income in perpetuity, and since the bond has a stated maturity date, its price would not decline by the full amount of the capitalized tax. Moreover, it would be necessary for the purchaser to have other investment opportunities not subject to this kind of tax. If every field of investment available to him were subject to a tax of the amount assumed in this instance, he might as well buy bonds as anything else. If other investment opportunities were available in which the tax were less, there would be a capitalization only of the smaller tax. For example, if one state should tax bonds at 1 per cent of the value, while other states exempted bonds as such but levied a tax of, say, 5 per cent on incomes, a purchaser in the income tax states could afford to buy the 3 per cent bond at a price that represented capitalization of the tax of $1.50 on the income.

Tax capitalization is therefore a process by which the burden of a future series of tax payments is placed on the present owner of an income-producing asset. The preceding discussion has indicated two essential conditions for capitalizing a tax. They are: (1) the tax must be unequal or exclusive, since, if it applies generally and leaves no alternative areas of investment at more favorable tax terms, there is no advantage to capitalize; (2) the commodity taxed must have a prospect of fairly long-term income value from which a capital value can be determined. Land and long-term securities fulfill the latter requirement. Durable goods, such as machinery, have a certain period of useful life, but their value will be influenced by the cost of production as well as by the net return they are expected to produce. Consequently, that value is not determinable solely by reference to income.

## ADMINISTRATIVE PROCEDURE OF TAXATION

There are certain definite steps or processes, occurring in a regular sequence, in the imposition and collection of any tax. The taking of private wealth for public use is always a serious matter, to be done according to rules of procedure that have been developed to protect both the taxpayer and the revenue. In some cases the administrative steps are clearly distinguishable; in others they have been telescoped together. The several stages are given below in their usual sequence.

**Determination of Tax Base.** The tax base refers to the objects or classes of objects to be taxed. It may be income, or a class or classes of property, or a single commodity such as tobacco, or certain kinds of imported goods. The tax base is always determined by the law which provides for the tax.

**Assessment.** An assessment is a determination of the size or amount of the tax base. The procedure of assessment will depend upon the character of the tax. Real property, for example, is taxed according to its value. The assessment of real property is the determination of the taxable value of the several parcels of property. Whisky is taxed by the gallon, and assessment means measuring the number of gallons. The income tax payer makes his own assessment in filling out the income tax form, in which he computes the amount of his taxable income. Self-assessment is relatively rare. Ordinarily, it is done by elected or appointed officials.

**Levy.** The tax levy is the formal order for the payment of a tax on the base as assessed, at a specified rate or rates. The levy is contained in the law in some cases, such as the tax on incomes, on gasoline, and on inheritances. Levy of property tax is authorized by law, but it is actually made by the local governing body after the tax requirement is determined in the local budget.

**Determination of Tax Due.** Determining the tax due is essentially a clerical matter. It involves multiplication of the taxable base by the rate or rates of tax to be imposed. It is done by the taxpayer for the income tax, and by clerks in the office of the tax collector in most other cases.

**Review.** Because of the many points at which human judgment and discretion enter into the taxing process, it is always necessary to provide for a review of decisions. The human factor is particularly significant in income and estate taxes at the federal level and in property and income taxes at the state level. The review may be made by an administrative body or by the courts. Factual issues are likely to be better handled by administrative review than by judicial process, but legal issues are always taken into the courts.

**Collection.** All of the preceding steps have had, as their combined purpose, the fair determination of the tax liability.

But the tax must be collected if the taxing process is to serve its ultimate objective. Yet, in many cases, less attention has been given to efficient collection than to the other aspects of tax administration. A corollary of collection is the refund of taxes erroneously or illegally collected.

**Penalties.** Any law that does not provide a penalty for noncompliance is likely to go unheeded and tax laws are no exception. There is a wide range of penalties in tax laws from interest on unpaid installments of a tax to heavy fines and prison sentences for willful tax evasion.

## TYPES OF TAXES

**General Grouping.** There is no authentic formal classification of taxes. The following grouping, however, may be used to indicate certain differentiating characteristics: (1) taxes on persons as such, including the poll tax and the individual income tax; (2) taxes on things, including property taxes and commodity or excise taxes; (3) taxes on acts and privileges, including business taxes, sales taxes, inheritance taxes, and various license taxes. Some legal commentators have suggested that the term "excise tax" includes all kinds of taxes except a capitation, or poll tax, and a property tax. This is a way of indicating the scope, and the limitations, of the federal taxing power under the Constitution rather than a descriptive classification. That instrument authorizes federal use of excises, but requires apportionment of a direct federal tax among the states according to population. The Sixteenth Amendment removed this limitation as to the income tax, thereby leaving the poll tax and the property tax as the only kinds of taxation not unrestrictedly available to the Federal Government under the broad definition of an excise.

**Income Tax.** The idea of taxing income is very old. The tithe of Biblical times was a percentage of the increase of flocks and herds, and this increase was about the only measure of income in a pastoral economy. It was noted above that income taxes were known in Egypt under Roman rule; they were also familiar to the Romans at home. All kinds of taxation fell into relative disuse with the passing of Roman civilization and the rise of feudal-paternalistic states. Some of the early English levies, notably the "fifteenth" and the "tenth," had characteristics of an income tax, although they were nominally levied on assets.

Twice during the long period of the Napoleonic wars England made use of an income tax. On each occasion it was repealed with the passing of the immediate emergency, amid general rejoicing. The third enactment, in 1846, was the foundation of the present English tax. A few of the American states had experimented with taxes on income during the nineteenth century, and during and after the Civil War a levy on income had some years of tenure as a federal tax. In 1891 Prussia introduced a system of graduated rates which was then regarded as a model. The English income tax was levied at a proportional rate until 1907, when a graduated super tax was introduced. France did not adopt the modern type of graduated income tax until 1917.

In the United States, a federal income tax was enacted in 1894, but it was thrown out by the Supreme Court on the ground that a tax on the income from land was the same as a tax on land and hence a direct tax, subject to the apportionment rule. A parallel case decided at the same time held that a tax on the interest of municipal bonds was the same as a tax on the bonds, and hence a federal tax on an instrumentality of state government. It therefore contravened a principle of federalism pointed out by Chief Justice John Marshall, to the effect that neither government in a federal union should tax the agencies and instrumentalities of the other. The Sixteenth Amendment, effective as of Mar. 1, 1913, authorized the taxation of incomes without regard to an apportionment according to population.

*General Income Tax Problems.* One of the most important problems of income taxation that affects all taxpayers, individual and corporate, is the determination of income. This is particularly the case with respect to business income. It is frequently assumed that income is something which can be ascertained with final accuracy, like the answer to a problem in arithmetic. Such, however, is not the case. Business income, for any one year, is at best a reasonably close approximation, not an absolute finding of fact. The reason is that at many points it is necessary to rely upon judgments, estimates, and opinions. This is true because, as a whole, business operation is seldom, if ever, completely concluded at the time an income tax return must be filed. Business firms make an annual cut-off for the purpose of accounting to stockholders, and also for tax reporting. But it is not possible, except in the simplest sort of business, to fix precisely the profit or loss outcome of a large series of operations, some of which may extend into the report year from a previous year, while others, having been started in the report year, may extend into a future year. In addition to these large areas of judgment, there is the determination of depreciation, the valuation of inventories, the proper amount to be added to bad debt reserves and various other matters that involve judgment or opinion. The objective of business accounting is to arrive at as nearly correct an approximation of the results of operation as possible. Every accountant knows that it is, after all, only an approximation which will be revised and improved in the light of subsequent developments.

The point of emphasis is that the results of business accounting, assuming that some adequate system of accounting is consistently followed, should be given great weight in arriving at taxable income. This is particularly worthy of note in the case of some of the important charges and deductions against gross income which business regularly makes. Some examples are given in the following discussion.

Depreciation. The purpose of depreciation accounting is to provide, out of income, for the recovery of the investment in tangible, fixed assets while they are still in use. The value of these assets disappears, first, through wear and tear in use, and second, through obsolescence. As the tools and other equipment used in production are worn out, or become obsolete, the expenditure for their original acquisition must be recovered; otherwise the firm will eventually find itself in a position where it cannot continue operation. It will, in fact, have used up its capital. Proper charges for depreciation and obsolescence are as much a part of the cost of production as are the payments for labor and materials. The principal difficulty encountered under the income tax is the determination of what constitutes proper charges for these purposes.

Business Net Losses. In view of what has been said about the results of business operation being, in a substantial degree, determinable by reference to judgments and opinions, it follows that the fact, and the amount, of a loss for a given year is an approximation similar to that which would indicate a profit. Subsequent developments may lead to a correction, as illustrated by the later discovery that the allowance for bad debts is greater than actually required.

There is general agreement among accountants and tax experts that business losses should be offset against the business profits of other years before a net profit or net income can be shown on which a tax may be levied. In actual operation, a business must absorb or offset its losses against its

profits; otherwise, if all profits were distributed, without regard to losses, the capital would in time be dissipated, since the loss outgo means a payment of part of the business expense out of capital funds.

Income tax laws ordinarily permit an adjustment of net business losses against net profits. This adjustment can be made by carrying the loss backward in time and revising the profit statements of earlier years, or it can be carried forward as an offset against the profits of future years.

Capital Gains. A capital gain is a gain which is realized from the sale or exchange of a capital asset. The Supreme Court of the United States held long ago that such gains are income. The income tax law, since 1921 at least, has provided a separate method of taxing capital gains if the capital asset has been held longer than a period stated in the law. Short-term gains, that is, gains from sale or exchange of capital assets held for a period shorter than that specified, are taxed in full along with other income. Capital gains and losses may be offset against each other, and net capital losses may be carried forward. But the amount of such loss that may be deducted from other income is limited to the loss itself, or to $1,000, whichever is smaller.

The principal theoretical issue is whether or not a capital gain is really income, despite the Supreme Court's opinion. For the most part, such gains are not regarded as income in England. Capital assets are defined in such a way that the principal class of such assets consists of stocks and bonds. They would also include commodities traded in on the produce exchanges, and property generally which is not accounted for in inventories or which is not subject to ordinary depreciation accounting.

*Individual Income Tax.* There are certain matters which are of particular significance in the taxation of individual incomes. Some of these follow.

Concept of Individual Net Income. Income, as such, is not defined by the Sixteenth Amendment. The tax is levied on taxable net income, which means the total of certain specified types of receipts, less certain specified types of deductions. The deductions allowed from gross income are of two classes. The first includes designated kinds of costs of gaining the income, such as wages, costs of materials, maintenance of property used in getting the income, depreciation, interest, taxes other than the income tax itself, losses not covered by insurance, bad debts, and similar costs of a business nature, and also a limited amount of charitable contributions. Deduction of these allowable items from gross income results in net income. The second class of deductions consists of the personal exemptions and dependency credits allowed to the taxpayer. The amount remaining after taking out the second group of deductions is net taxable income.

Net income is a business concept and it has only an artificial meaning when applied to the individual. The latter may deduct certain types of expense that are identifiable as business expense, such as wages paid, depreciation on property used, costs of materials and supplies, fuel, and other maintenance costs related to property used in gaining income. But these items are appropriate only for individuals deriving income from business operations. The person whose income is derived as wages or salary for personal services has little benefit from them, yet he obviously has his own costs of gaining income which are analogous to those involved in getting business income. Many of these costs to the worker are grouped under the head of family or living expenses and are not deductible.

Personal Exemptions. A great deal of confusion about the personal allowances to the taxpayer and his dependents is typical of general tax problems from year to year. This kind of credit was first introduced under the early English income tax and there was a great deal of debate over the propriety of providing an amount of income, free of tax, which was supposed to represent the cost of subsistence. It has always been at or near a bare subsistence minimum in the English law. Because of this precedent, exemptions were incorporated into the United States law. There has never been a pretense, however, that the amount allowed was in any way related to subsistence cost. Rather, the allowance has been determined mainly by fiscal expediency. The first federal income tax act, passed in 1913, provided an exemption of $4,000 for a married couple and $3,000 for single persons. The credit for dependents was $200 in the act of 1916 as against $600 in 1948. The exemptions were lowered during World War I and raised again during the 1920's, and again lowered during World War II. The act of 1948 set the amount at $600 for the taxpayer and $600 for each of his dependents.

It is obvious that the number of taxpayers subject to income tax will be directly affected by the exemption level because of the distribution of incomes among the lower income groups.

Rates of Individual Tax. There is no principle by which the proper rates to be imposed on individual incomes can be determined. The practice of taxing such incomes at progressive rates is almost universal. Proponents of a system of moderate rates, as opposed to extreme progression, have argued that excessive rates have a destructive effect on savings and investment, on the readiness to assume risks, and on the enterprise incentives. They have held that as much or even more revenue would be obtained from a system of moderate rates as from a system of excessive rates. The concept of moderation is itself relative. Under the Revenue Act of 1928 the maximum rate of federal tax was 25 per cent, applicable to surtax net income of $100,000 and more. During 1947 and 1948 a goal of 50 per cent as the maximum rate on income of $100,000 and more proved politically impossible of attainment. As the war tax rates stood until changed by the act of 1948, there was a rate of 50 per cent or more on all taxable income above $18,000. Under the act of 1948, the 50 per cent level was reached at $32,000 of taxable income.

Tax Withholding. The payment of a part of the tax at source, by deductions from payments for personal services (wages, salaries, commissions, and other similar payments) is a necessary procedure while there are many millions of small income earners subject to income tax. It is, in fact, considered the only feasible method of collecting the tax, for the administrative expense of securing personal returns from so large a group would absorb all that was collected. Persons with wage or salary incomes up to $5,000 and with no more than $100 of other income can pay their entire tax by the withholding method.

Declaration of Estimated Tax. Every person who anticipates an income of more than $5,000 must execute a declaration of estimated tax for the year. This declaration is to be filed by March 15, accompanied by payment of at least one-fourth of the estimated tax due, taking into account the tax, if any, to be withheld during the year. This is a valuable feature of the income tax procedure. It puts the payment of income tax on a current basis, that is, payment out of income as received. Prior to its adoption in 1943, there was a lag of one year between the receipt of income and the payment of tax thereon. This became acutely embarrassing for many when retroactive increases of tax rates were

made, or when current income unexpectedly fell below the prior year's income.

Tax Treatment of Dividend Income. In legal theory, a corporation is an entity separate and distinct from the group of stockholders. It is a legal person. Its assets, debts, and income are distinct from those of its stockholders. Yet the body of stockholders together own the corporation, and they are the beneficiaries of any distributable income it may earn.

*Corporation Income Tax.* All income inures eventually to the benefit of individuals. From this general proposition it is possible to deduce that all income should be taxed to individuals and that business, as such, should not be levied upon. Some of the difficulties of such a course were noted above. The fact is that there will probably always be taxation of business, with or without some kind of recognition of the burden by credits or allowances to individuals.

An interesting and important question is that of the relative effect of a tax on corporation income, as compared with a tax on individual income, from the standpoint of investment incentive. Some would exempt, or reduce greatly, the corporation tax and make up the revenue loss by increasing individual taxes; others would do the opposite by keeping fairly high taxes on corporation income in order to lower individual tax rates. The process of saving and investment is motivated principally by the prospect of return commensurate with the risk. If this return is inadequate, investment will diminish. It makes little difference whether the inadequacy is caused by heavy taxes on the corporation's income or on the individual investor's income.

Retained Earnings. The United States income tax law has long contained a provision imposing a special tax on earnings deemed to have been improperly retained in order to benefit large stockholders. The purpose of the special, or penalty, tax is to force distribution of all, or a large part, of the income to stockholders where it would be subject to the heavy rates of the individual tax. The fact that dividends do not account for a substantial portion of the corporation's income is usually deemed to be evidence of an intent to shield stockholders.

Intercorporate Dividends. If one corporation owns stocks issued by other corporations, it naturally receives dividends thereon as paid. Since the distributing corporations have already been taxed on their respective incomes before paying dividends, it is logical to exclude such dividends from the taxable income of the recipient corporation to avoid double taxation. In 1948 the federal law permitted deduction of only 85 per cent of dividends received, thereby taxing doubly the other 15 per cent.

Consolidated Returns. Corporations which are members of a closely affiliated group of companies ordinarily make a consolidated return for the information of their stockholders. In 1948 the federal law permitted this kind of return for tax purposes, but imposed an additional tax of 2 per cent on the income shown in such a return.

**Excess-Profits Taxes.** In World War I and again in World War II, the United States government taxed so-called "excess profits." The vast destruction of modern war means a great expansion of production, particularly in the lines of goods required for the war effort. Modern wars have been financed in part by methods that are inflationary, and the inflation leads to greater volume of business even among the businesses that are not directly engaged in war production. Greater volume results, for a time at least, in larger aggregate profits. Hence the demand that some kind of special tax be imposed on these profits.

The measurement of excess profits can never be exact in an absolute sense. The tax laws, therefore, have fallen back upon arbitrary standards for this purpose. In the excess-profits tax in force during World War II, alternative standards of excess profit measurement were provided. One was an earnings base, being 95 per cent of the average earnings of the base period from 1936 to 1939, inclusive. The other was an invested capital base, on which excess profit was determined to be the amount of profit above stated percentages of the invested capital. Each corporation was permitted to choose between these methods.

**Poll Taxes.** The other method of taxing persons as such is by a poll, or head, tax. This tax was used by the ancients to emphasize inferiority of political status. It was used by the American Colonies, and was an important cause of Bacon's Rebellion in Virginia in 1676. Yet, almost a century after that episode, it was still the most productive of all the Virginia taxes. The poll tax has often been criticized because of its use in some states as a prerequisite to voting. Yet it is levied directly under the constitutions, or required by constitutional provisions, in twelve states, and it is permissive in all other states except Maryland, Oregon, Ohio, and Utah, whose constitutions forbid such a tax. The Maryland constitution says that a poll tax is "grievous and oppressive." The receipts are usually devoted to schools, or to roads and streets. In Connecticut, it is used for old-age assistance. Vermont applies part of the yield to this purpose, and in North Carolina a part is used for support of the poor. The revenue aspect of the poll tax depends upon the wealth and income of the state. In some states it produces more than the inheritance tax, even when administered indifferently.

**Property Taxes.** The property tax is one that is levied on all forms of property, or on designated classes of property, according to value. This tax was once an important source of revenue for the states and their local subdivisions. It has since been relinquished very generally to local units of government because the states have developed other forms of taxation. In 1915, for example, property taxes comprised 50 per cent of total state tax revenues. By 1942 these taxes supplied only 5.4 per cent of state tax receipts.

The theory of a property tax is that the value of property owned is a fair measure of the tax which the owner should pay. This theory was reasonably correct under primitive economic conditions, such as existed in the American Colonies and in the early part of the nineteenth century. Land was then abundant and cheap, and it was available somewhere to all but the thriftless and the lazy. The other wealth of the community consisted mainly of buildings, livestock, simple tools and machines, and merchandise. There were few assets other than visible property by which to measure wealth and income. The growth of the modern business economy, with a banking and credit system and business corporations having a wide array of securities, meant the rise of forms of wealth that were not openly visible. Moreover, the increasing specialization of labor led to the rise of numerous classes of professional workers who obtained income through services rather than from the ownership and use of property. Such groups would pay no taxes directly in a community that relied solely upon the property tax, and the invisibility of the rights and titles represented by stocks, bonds, mortgages, and bank credits presented an insurmountable problem of assessment. Many states have abandoned the attempt to assess and tax so-called intangible property because of these assessment difficulties. In those states the property tax is limited to real estate, namely, lands and buildings, and in some other cases to certain forms of tangible personal property such as livestock, machinery, and merchandise.

*Assessment Systems.* The principal practical problem presented by the property tax is that of valuation, or assessment. The historic rule has been that each parcel or item of property shall be assessed at the value it would command in a free market transfer. Again, this rule was reasonably valid in a primitive society in which property units were small and trading in them was both general and active. Under such conditions the property assessor had at hand a ready standard of reference by which to judge reasonably well as to what a farm, a house and lot, a horse, or a cow would be worth in the market, even if the particular item of property had not been offered for sale. This rule of fair market value ceases to be applicable with the rise of large property aggregates such as railroads, rolling mills, office buildings, and the like. There is no market in which these kinds of property units are bought and sold on a scale that would provide a guide to fair market value. Complicated assessment systems have, perforce, been developed to deal with modern assessment problems, but there are few places in which recognition has been given to the fundamental fact that some other method of taxation is required for the classes of property for which the market no longer provides an adequate valuation guide. In England property is taxed on the annual income value rather than on the market or capital value.

*Effectiveness in Localities.* The property tax, particularly on real property, is a natural source of local revenue because this is the one form of property that cannot be concealed or removed from the jurisdiction. It is for this reason that the property tax has been so largely relegated to local use. With the expansion of local expenditures there has been a tendency in some cities to overload this tax. The consequences of such a policy are particularly disastrous under depression conditions, since there is no enforcement procedure competent to deal with wholesale property tax delinquency such as was experienced in many places during the early 1930's. Broadening of the local revenue base has been enforced by a number of states by imposing limitations upon the maximum rate of levy, but the protection thus afforded against excessive taxation is only partial unless there is also effective administrative or judicial control of the assessment procedure.

**Taxes on Commodities.** The taxes on selected classes of goods are, in one respect, a kind of tax on property. They may even be assessed, as is the property tax, according to the value. Another method of determining the taxable base is by levying the tax on some specific quantitative unit, such as the pound, yard, or gallon. There is, however, an important procedural difference. All property is assessed as of a given date, but the commodity taxes are imposed at the time of sale, or at the time of removal from storage in bonded warehouses. The general classes of commodity taxes include those on imported goods, which are called customs duties, and those on certain articles of domestic production, which are called excises.

*Restrictions on States.* The Federal Government levies both customs and excises. The states are forbidden by the constitution to impose customs duties, but they are entirely free to levy excise taxes. The restriction on state taxation of imported merchandise applies only to taxes laid at the time of importation. After foreign goods have become part of the general stock of goods offered for sale in a state, they may be taxed by it in any manner generally applicable to other goods. For example, a state may not levy an import duty on foreign perfumes, but once these perfumes are offered for sale in a department store, they may be taxed as merchandise under a property tax, a state cosmetics tax, or a state sales tax.

*Customs Duties.* Customs duties are imposed, in theory, for revenue purposes, but in practice they have long been imposed for other reasons, chief of which is to restrict, or even to prohibit, the inflow of foreign products likely to compete with domestic products. The arguments for protective tariffs are essentially political rather than economic and fiscal. As a revenue source, the customs are now relatively unimportant, the yield being only about 1 per cent of total federal revenues of the United States.

*Excises.* The federal excise system has varied with the revenue need, both as to extent and rates. Such taxes were used in the early days of the Republic, and again during the War of 1812. They disappeared again until the Civil War, after which the taxes on liquor and tobacco became permanent. World War I caused a broadening of the system, but many of the war excises were discontinued during the 1920's. There was some expansion of the system during the 1930's and an enormous increase of both rates and coverage during World War II.

Wide difference of opinion exists regarding the proper place of the excises in the federal tax system. At one extreme are those who would abolish all excises except the taxes on liquor and tobacco. At the other extreme are those who would expand the excise tax yield to constitute a substantial proportion of the total federal receipts.

**State Taxes on Commodities.** The states have been driven, by their revenue needs, into the taxation of a considerable list of commodities. All states that adopted the licensing system for the sale of alcoholic beverages after the repeal of the Eighteenth Amendment tax these beverages. Cigarettes are taxed in more than thirty states. Gasoline is taxed in all states. Beyond these important instances, there are scattered cases of state taxes on other commodities, but they are of little importance for the revenue. Liquor, tobacco, and gasoline are also taxed by the federal government. They constitute an important segment of the perennial problem of federal-state fiscal adjustment. Until the federal budget can be reduced there is little likelihood that the federal levy will be discontinued. Relinquishment of the gasoline tax to the states was recommended by the Committee on Postwar Tax Policy in 1945.

**Business Taxes.** Among the various ways of taxing business as such is the method known as the franchise tax. The business franchise includes different kinds of privileges, the number and importance of which depend upon the form of business organization. The corporation charter is a kind of business privilege. The size of the ordinary incorporation fee, usually about $25, indicates that no great value is placed on this particular privilege. Articles of partnership, moreover, may be drawn up and signed without the payment of any fee to the state.

The most important application of the franchise principle in the field of taxation is its use by the states in taxing business. In this sense it is a case of taxing the privilege of doing business within the state, and there can be no question that such a privilege is valuable in view of the authority of any state to exclude a given corporation or other business firm from doing business inside its borders if the state's rules and regulations are not observed. The accepted measure of the value of the franchise to do business within a given state is the net income derived from such business. A tax on the privilege of doing business, measured by the net income, is distinguishable from a tax on the net income.

The principal economic and accounting problem raised by such a tax is that of determining how much net income is realized from the operations within a particular state. If a

given company is operating in several states, and many large companies do more or less business in all states, it becomes important to have a reasonable rule for determining what part of the total income, which is naturally a product of the total operations, is properly taxable in any one state. Business records of receipts and expenses are seldom, if ever, kept on a state-by-state basis. In general, some method of allocation is necessary. Any allocation will be arbitrary, and the particular method used is less important than that there be reasonable uniformity of procedure. The various states have not accepted any one uniform method. The allocation system evolved in Massachusetts has been more generally accepted than any other, and it is generally conceded that it should, therefore, be introduced as the uniform procedure. In brief, its provisions are as follows:

(1) Investment and other nonoperating income is to be allocated within or without the state according to domicile or origin. For example, rents of real property located outside of the state are to be allocated to the state of origin. Income from investment is to be allocated to the state in case of a domestic corporation, and outside in case of a foreign corporation.

(2) Operating income is to be allocated on the basis of the following formula: one-third of the net operating income on the basis of tangible property within and without the state; one-third on the basis of the pay roll inside and outside the state; and one-third on the basis of sales inside and outside the state.

The sum of the fractions of net operating income obtained by application of the above formula constitutes the net income from the business done both within the state and without the state. This formula is considered sound, economically, since the principal components in the production of income are physical property or plant, workers employed, and sales. If such a formula were generally used, each state in which a given corporation did business would get its appropriate aliquot part of the company's total net income, and the several parts would add up to 100 per cent of the net income.

**Sales Taxes.** The sales tax is levied in various states at rates ranging from 1 per cent to 3 per cent. It has become, for the states that use it, one of the most productive of all state sources of revenue. In fact, it has become so embedded in state fiscal programs as to render unlikely any prospect that it will ever be abandoned. The sales tax is very generally imposed as a tax on the privilege of selling at retail. Thus it belongs in the general class of taxes on acts and privileges. The tax on this privilege is measured by an amount equal to a stated percentage of the sales during the year. The basis is net sales, which takes account of refunds, returns of goods, and so on. The dealer is the taxpayer, in that he settles with the tax collector, but virtually every sales-tax law provides that the tax shall be collected from the consumer, who thus becomes the tax bearer. While the incidence of the sales tax is generally on the consumer, there is nothing to prevent dealers from making a price adjustment that involves absorption of the tax.

**The Use Tax.** The complaints of dealers against the exemption accorded sales in interstate commerce led to the use tax, which is a device whereby the interstate commerce exemption might be circumvented. The use tax is a levy on the use, storage, or consumption of goods that would be subject to a sales tax if bought within the state. Thus, in legal theory, it is a tax on every act of use, storage, or consumption, regardless of the origin of the goods. All goods on which a sales tax has been paid are exempt from use tax. The courts have sustained use taxes. They are obviously not completely enforceable because of the impossibility of supervising the interstate transactions of all the citizens. The worst feature of this type of tax is that judicial sanction has been given to the efforts of the collecting state to compel business firms in other states to submit to audits of sales to customers within its borders. Mail-order houses are the principal targets for such extraterritorial audits. The precedent has been viewed by some as potentially dangerous, since it may lead to an extension of one state's authority to persons or businesses outside its jurisdiction of a wholly improper and undesirable sort.

**Motor-Vehicle License Taxes.** With the great growth in the use of motor vehicles, some system of identification became necessary for police control purposes and for the protection of owners. The method universally used is a registration of the vehicle, based upon evidence of ownership. One or two plates, or "tags," must be attached to the vehicle to indicate compliance with the registration requirement. It quickly became apparent that this practice could provide a lucrative source of revenue, and the rates established were set much above the costs of registration. This was considered a proper attitude in view of the strong public demand for highway improvement and in view, also, of the fact that the motor-vehicle revenues were used for road construction and maintenance. Broadly speaking, it was a case of applying the benefit doctrine of taxation.

**Miscellaneous License Taxes.** In the tax laws of the 48 states will be found a long list of occupations, activities, and transactions which are subjected to license taxes. The southern states in particular have traditionally applied a wide variety of such taxes.

**Death Taxes.** The transfer of property from one generation to another is probably as old as the institution of property itself. It may occur either by inheritance, which means succession in the family line, or by bequest, which means a disposition by will or testament. Two types of death tax have developed. One is the inheritance tax, which is based on the amount of property passing to each separate heir; the other is the estate tax, which is levied on the estate before distribution to the heirs.

Tax rate progression is very generally used in both forms of the tax. In the case of the inheritance taxes, there is frequently a dual graduation, one series of rates applying to the specific amounts and another to the degree of relationship of the various heirs to the decedent. There are good arguments in support of each form of death tax. For the inheritance tax it can be said that the tax burden is adjusted to the amount which each heir receives; and to the extent that the bequest indicates some exceptional ability to pay, the amount that each beneficiary receives is the proper measure in his case. But the inheritance tax presents a serious administrative problem, which also involves questions of equity, in the case of a bequest which is divided between a life tenancy and a contingent interest. The person who inherits only a life interest in property should not pay the full tax that is computed. On the other hand, the remainder inheritor has only a future interest which he may not live to enjoy. The apportionment of the tax between the two parties, and the time of collecting the residuary legatee's share, are matters that are extremely difficult of satisfactory solution.

The estate tax avoids this issue because it is collected on the net estate before distribution. But it does not conform with the so-called ability principle as closely as does the inheritance tax, if the estate tax rates are graduated.

Two problems of special importance in connection with

death taxes are: first, the question of domicile; and second, the question of contemplation of death.

The problem of domicile has arisen in the case of the state taxes. For a long time it had been assumed that a person could have only one domicile, one place which he regarded as his home. He might own residences, hunting lodges, or summer camps in other states, and he might divide his time among these various residences, but these facts were not deemed to contradict the basic fact of a single domicile. The matter is important only in the case of a large estate, and in recent years the states have had opportunity to engage in intense rivalry for the opportunity of levying the tax on these estates. As these cases went to the Supreme Court that body produced the doctrine that a person can have more than one domicile, in more than one state. The owners of these large estates, during life, had engaged in some questionable practices with respect to domicile in an effort to escape local income and other taxes, or to take advantage of particular state laws respecting the creation of trusts, and so on. The resulting field day that the states have had in levying multiple inheritance taxes was made possible by the decisions, but it was also a product of the juggling that had gone on before the death of the owners of these fortunes. Double or multiple taxation of estates is highly objectionable. The states had been well on the way to the elimination of this abuse through reciprocal agreements, but the new doctrine of double or multiple domicile has largely undone the results of the years of patient negotiation that had gone into the reciprocity movement.

During the development of the inheritance taxes it was possible to avoid the tax by making distributions of property during life. The gift tax was designed to prevent avoidance of this sort, but there still remains the question of whether or not a gift is made in contemplation of death. If this motive can be proved, the transfer is taxable at estate tax rates rather than at gift tax rates, which are, in the federal law, only three-fourths as high throughout the rate scale. One solution has been to provide that if death occurred within a stated period after the gift was made, it constituted prima facie evidence of being a transfer in contemplation of death. But death comes at all ages. A person in middle life, in good health, may die suddenly. It is hardly tenable to hold that such a person had in mind his early demise in making gifts of property to his wife or children. On the other hand, proof that he did not is hard to obtain, especially after his death.

Aside from this issue, for which there is no easy solution, there is the question of what constitutes a gift. The question does not arise in the case of complete, outright, irrevocable gifts or transfers, but rather in the case of trusts which involve reservations of one sort or another. Settlers of trusts have sought in various ways to reserve powers, or to grant powers, with respect to the property conveyed, and many of them have encountered difficulties because their reservations were such that a clean-cut, outright gift was not made.

### EFFECTS OF TAXATION

**Burden on Taxpayer.** The principal effect of taxation, one which should never be lost from sight, is that it is a burden on the taxpayers. Since there must be government, it follows that there must be taxes. Notwithstanding that the services of government are, to a certain level of cost, advantageous to society in general and to the profitable conduct of business in particular, it is still true that the taxes levied to defray this cost are a burden on those who must pay them. They have less of the fruits of their own labor after the taxes. Government spending and taxing mean that the decisions with respect to the application of a portion of private income are made by others. As taxes increase, the share of the taxpayer's income over which he has no control rises.

H. L. L.

**TAXIDERMY.** The art of preserving skins and mounting them in lifelike positions. The word is taken from the Greek *taxis,* meaning order, and *derma,* the skin.

When it was that man first became interested in the preservation of animal specimens in a more or less lifelike state we cannot say, but there are a few brief accounts here and there that give us a suggestion that the art of taxidermy may have been carried on from quite remote times. A story of Hanno, the Carthaginean navigator, for example, describes the discovery and capture of what were probably gorillas five hundred years before the Christian Era and states that the animals were killed and their skins taken to Carthage. Pliny tells us that these skins remained in the temple of Astarte until the year 146 B.C.

When the Egyptian tombs, of an even earlier period, were opened, many embalmed specimens of cats, dogs, monkeys, ibises, and other animals as well as humans were found. But this art of embalming, as the Egyptians knew it, was invented to satisfy their religious beliefs and cannot come under the heading of taxidermy, for taxidermy proper attempts to reproduce specimens that are both true to nature and look alive. The Egyptian specimens were merely preserved bodies.

The first inkling we have of an attempt at mounting birds was in Amsterdam early in the sixteenth century; here the skins were arranged on a system of wires and filled with spices to preserve them. Late in the same century we find mention of taxidermy in Shakespeare's *Romeo and Juliet* (V,1):

> I do remember an apothecary,
> And hereabouts a' dwells, which late I noted
> In tatter'd weeds, with overwhelming brows,
> Culling of simples; meagre were his looks;
> Sharp misery had worn him to the bones:
> And in his needy shop a tortoise hung,
> An alligator stuff'd and other skins,
> Of ill-shap'd fishes.

The first publication on the art of taxidermy was written in France in the year 1687, and a German writing issued at Leipsic in 1778 gives a description of methods used at that time. H. T. Race of Denmark published a book in 1842, and there was one by Nathaniel Whitlock of London 1831. Though the earliest publication of this kind to appear in the United States was in 1865, taxidermy work of the highest standards of any in the world has been produced here.

Early methods used in the art were crude indeed. The skin was taken off the animal by means of an incision along the stomach. It was then pickled in a solution usually made of salt and alum in water. After about one week in this, the skin was rinsed in water and the hair dried in warm sand or sawdust. The legs, head, and tail were then wired and these wires were twisted together inside the body cavity. A soft filling such as straw, grass, and, more recently, wood wool was used to stuff the skin. The incision was then sewed together and the animal was placed upon its feet and fastened by the protruding wires or rods.

From these crude beginnings have evolved modern methods of taxidermy. By these methods the taxidermy artist can reproduce an animal that lacks nothing save motion, as far as the eye is concerned. The preserved skin is fitted and glued fast to a plastic form that has been modeled to look

exactly as the original animal's body would be if the skin were removed. The tense muscles, tendons, and surface veins are beautifully reproduced. From this description one can readily see why it is no longer correct to speak of a "stuffed" animal; modern taxidermists "mount" the animal's skin. The art is so highly specialized that the mere knowledge of methods no longer spells success; it is also essential to have an intimate knowledge of the anatomy and habits of living animals.

Following is a brief description of methods used in preparing the different forms of animal life.

**Birds.** As soon as possible after the specimen is killed the blood is washed off the feathers. Shot holes, mouth, and nostrils are filled with absorbent cotten. Water-color notes are taken of the nonfeathered parts, such as the eyes, beak, feet, and wattles if any, and notes are made of the bird's sex and of the locality and date the specimen was killed. Unless one has a series of measurements, the total length and length of wing should be recorded.

After these preliminary notes have been taken, the actual work on the specimen begins. The feathers on the breast are parted and an incision is made from the center of the breast bone to the vent. The skin is now peeled from the body on each side of the incision until the knee joint is exposed. Powdered borax is sprinkled on the flesh to keep the feathers clean and the fingers dry. After the legs have been severed at the knee joint, the skin around the tail area is carefully loosened and the vertebra which holds the tail is severed, care being taken not to cut the tail feather quills. Next the skin is turned down over the back until the wing joints are reached, borax being sprinkled whenever necessary. The wings are cut free near the body and the skin is turned further wrong side out down over the neck and on over the skull until the ears are reached. Here the skin is cut close to the skull or pulled out of the ear socket. When the eyes are reached, a cut is made through the thin, bluish membrane, care being taken not to cut the eyelid. The skin is then gradually peeled forward over the skull until the base of the beak is reached. The skull is left attached here, and the neck is cut loose from the skull. Birds with large heads will have an extra incision made on the back of the head in order to skin out this part, since the skull is too large to allow the neck skin to be turned over it in the usual way. Ducks, woodpeckers, and a few other birds will require this treatment. Next the eyes are removed and a deep cut is made into the roof of the mouth and back to the base of the skull. This piece is detached and the brain is removed through the opening. The remaining flesh is now cleaned from the skull, and the skull, head, and neck skin are painted with arsenic solution; the eye sockets are filled with cotton, and the head skin is then turned back over the skull, beginning at the base of the beak. To smooth the feathers on the head a blunt instrument like a knitting needle is used; this is passed through the eye opening and moved carefully back and forth under the skin.

In the next step, the wing skin is turned down over the first joint and the flesh removed. The legs are turned down to the heel or, in most birds, where the feathers stop. The muscles are then cleaned off, leaving the bones intact. This part of the leg skin is painted with arsenic solution and the leg bone is pulled back into the skin; the bottoms of the feet are now opened and the large tendons are pulled from the legs. The tail area is cleaned next, care being taken to remove the oil sacs above the tail. All fat and flesh are now cleaned from the skin, borax being used to absorb any free oil. The under side of both wings is opened, all flesh is removed, and the skin is painted well with arsenic solution. This incision will not have to be sewed up if the bird is to be mounted with closed wings. Finally, the rest of the inside of the skin is similarly poisoned.

As a base for mounting the skin, a body is carved out of balsa wood, using the natural body for a guide. A sharpened wire is run through where the neck joins the body and a neck of cotton is constructed, thread being used to wind it. The wings are wired by running sharpened wires from the inside of the skin all the way to the tip of the wing bones. About one half inch of the end of the wire is turned up at right angles and forced through the wing bone, coming through on the outside of the wing. The wire is tied to the bone in several places. The legs are treated in the same way by running the sharpened wire through the sole of the foot and continuing up the back of the bone. The wire is tied as before and the muscles replaced with cotton and thread. Now the neck wire is inserted through the opening in the skin, and the artificial neck is run all the way to the base of the skull, the protruding neck wire coming out the mouth. The wings and legs are fastened in their proper positions by running the wires through the body and turning them back on themselves in the form of a staple and forcing them back into the balsa body, using the natural body as a guide. Next a wire is run through the base of the tail and fastened to the body in its proper place. The incision is sewed up, and the wings, legs, and head are bent into their natural positions. The bird is then set on a perch, the protruding leg wires being used to fasten it by running them through holes drilled in the perch.

Wherever necessary, the skin is arranged with a pair of tweezers and the posture of the bird is corrected. The feather tracts are arranged in their proper places. Now, artificial glass eyes are inserted, a small portion of papier-maché being used in the sockets, and the lids are arranged around them. The tail is fastened between two pieces of cardboard with pins, and thread is wound carefully around the bird to keep the plumage smooth until the skin is dry, which will take about two weeks. When the skin is dry, the thread and all protruding wires are cut off and the cardboard is removed from the tail. Finally, the colors are restored to the beak, legs, and other faded parts by means of the sparing use of oil paints.

**Mammals.** Detailed measurements are first taken of any mammal that is to be mounted. Plaster-of-Paris casts are made of the face and of any other parts that the preparator thinks necessary. These are made both before the skin is removed and after. The opening cuts are then made, the first being made in a straight line from a point between the front legs back along the stomach to the vent and on out to the tip of the tail. Another cut is made on each leg, beginning at the hoof or foot and continuing up the back of the leg to meet the stomach incision at right angles. If the animal has horns, an additional cut must be made on the back of the neck continuing to a point about three inches back of the horns. From here an additional incision is made to each horn. The skin is removed completely if the animal is large.

Small animals are treated a little differently. One incision is made on the stomach, as in birds, and the tail is stripped from its sheath from the inside. The leg bones are left attached to the skin at the feet and are cleaned of flesh. After the skin is scraped clean of all fat and flesh it is washed in soap chips dissolved in water and then rinsed in water, degreased in benzene and alcohol, and dried in sawdust. It is then mothproofed with arsenic solution. The mounting operation is very similar to that of birds. An artificial body is

made. The legs are wired, and the muscles are built on with excelsior or carved in balsa wood. The body is inserted, and the legs and tail are fastened in their proper places. The incision is sewed up, the animal is placed on its base, artificial eyes are set in place, and the mouth and nose are shaped with papier-maché.

The large animal skin must be spread out flat, thoroughly salted, and rolled up over night. It is then placed over a beam and scraped free of flesh and fat. The ears, eyes, lips, and nostrils must be split on the inside, the cartilage removed, and the skin well salted again and allowed to dry in the shade. The skin is then put through the tawing process to make it soft and pliable.

There are two processes by which skins are prepared for mounting purposes. One is the tanning method, by which skins are actually turned into leather by the use of a pickle made from the barks of certain trees and from plants that contain tannic acid. Skins of the elephant, rhinoceros, and hippopotamus are prepared for mounting by using this pickle. The skins, which are very thick, must be shaved down with special knives to an even thickness of one-quarter inch. An elephant skin is three fourths of an inch to an inch in thickness when removed from the animal; this must be shaved down soon and is a herculean task in itself. When shaved, the skin is placed in the pickle bath. These heavy skins must remain in the solution until the pickle penetrates all the way through, which takes several months. When this process is complete, the skin is washed in water, oiled, and placed in large revolving drums containing hard-wood sawdust; several oilings may be required before the task is completed. When finished, the leather resembles that which is used in the making of shoes.

The second process is called tawing and is used on all skins that are covered with hair or fur. Salt and alum are mixed with water, and after the skin has been shaved down to an even thickness as before, it is immersed in the pickle

*Typical preparation of large bird (restoration of extinct moa by Georgt Adams, Chief Taxidermist, American Museum of Natural History): (upper left) armature set up and barreled out with wire netting; (upper right) netting covered with squares of burlap dipped in wet plaster; (lower left) anatomical details carefully modeled in clay (lower right) completed specimen, with original skin fitted over*

and left there from one to two weeks, depending on the kind of skin. The purpose of the pickle is to break down the glue in the skin and leave the fibers free for softening. When the skin is removed from the pickle bath, it is washed in water and hung up to drain and dry a little. Beaver oil, a type of oil used for tanning purposes, is then brushed on the flesh side of the skin. The hide is placed in the drum as before and revolved until the oil is kneaded into the fibers. This process also cleans the hair, and any surplus oil that is on the skin is absorbed by the sawdust.

While the tanning is being done, an armature is set up which is a rough outline of the animal that is to be mounted. A pipe or wood upright is firmly fastened to the center of the base on which the animal model is to stand. To the top of this upright, which will be slightly higher than the back of the animal, is bolted a center board cut roughly to the shape of the animal's body. If the animal's anatomy is not well known, the cleaned skeleton must be wired on this board and the leg bones fastened in their correct places on the skeleton, using soft iron rods bound to the leg bones and fastened securely both at the top and on the base. If the taxidermist is thoroughly familiar with the animal's anatomy, the body skeleton can be left out and only the leg bones and skull used, fastening them to the center board with the iron rods. Black iron wire netting is used to cover this, barreling out the body to roughly the shape and size of the animal, using the measurements and the skeleton as a guide. Over this are laid burlap squares that have been dipped in liquid plaster of Paris. When this is dry, it forms a strong support over which the figure of the animal is modeled in clay. Every surface muscle, tendon, and vein that will show is carefully worked out. A plaster of Paris piece mold is then made of the clay model, and a light reproduction of the clay figure is made in this mold, using wet building paper that has been torn in strips two or three inches wide and coated with paste. Layer upon layer of pasted paper is pressed into the mold until the proper thickness, depending on the size of the animal, is built up. When this is dry, the halves are fastened together. Iron rods that have threads on their bottom ends are bent to the shape of the legs and fastened inside, leaving the threaded ends protruding from the bottoms of the feet. When thoroughly dry, this form will be very light and strong. One nut is put on each of the four leg rods, and the ends of the rods are run through holes that have been drilled in the base on which the animal is to be mounted; another nut is turned up on each rod from under the base and tightened to make the form stand rigidly. Horns or antlers are screwed to a block of wood that has been fitted inside the top of the head of the model. Wire is fastened where the tail should join the body, and this appendage is built up around the wire with excelsior or tow and covered with papier-maché. The form is waterproofed and coated with paste, and the skin, still wet with arsenic solution, is worked and fitted to the form. The leg and body openings are sewed up, and the skin is further worked into every detail of the form and held there with pins until the paste underneath is dry. The ears are stiffened and shaped with metal linings that have been made to the shape of the natural cartilages that were removed. The lips and nostrils are worked into the slots made in the form for them. Artificial glass eyes are set in their sockets either before the skin is put on or after, whichever the preparator wishes. The hair pattern is worked out as it should be in nature and the specimen allowed to dry out for two or three weeks. Then the pins are removed, the hoofs are cleaned and oiled, the eyelids and nostrils are waxed and varnished to look damp, and the animal is ready for exhibition after any faded colors have been restored with oil paint.

**Frogs, Salamanders, Snakes, and Turtles.** There are several methods of handling this type of material. A plaster-of-Paris cast is sometimes made. When this is dry, it is shellacked and painted to correspond with the specimen's natural colors noted while the animal was fresh. Turtles are also very often mounted by removing the lower half of the shell or by cutting a piece out of the bottom of the shell through which the legs, head, and tail may be skinned. Leg bones are left attached to the toes. The skull cannot be skinned out, since the skin grows too closely to it, and the face muscles and brain are cleaned out through the neck opening and the eyes removed from the outside. Wires are placed in the legs, tail, and head and bound to the bones with thread. The muscles are replaced with tow and a coating of maché, and the skin is turned back over them. The leg, tail, and head wires are then fastened to a small piece of cork or balsa wood, the animal's legs and head are bent into the attitude it is to assume, the shell is blocked up to the height it should be in life, and the specimen is allowed to dry out. This done, the shell is replaced with wire and maché, and the faded parts are recolored after the artificial eyes have been inserted and waxed. Snake skins can be mounted in the same general way as those of birds by opening on the stomach the full length, removing the skin, and cleaning and mothproofing it in arsenic solution. The form is made by modeling or casting before the skin is removed, and the re-

sulting form is then used to fit the skin. The colors as they were in life are restored in oils as before.

Specimens of frogs, salamanders, snakes, turtles, and even fish are being preserved at the American Museum of Natural History in New York by the paraffin infiltration method. The specimen is first set up in Bouin's solution and then dehydrated in several baths of alcohol of gradually increasing strength until absolute alcohol is reached. It is then transferred to warm paraffin for a length of time depending on the type of specimen. If any of the colors fade, they are touched up with oil paint. These several types of specimens, as well as lizards, are also made up artificially in celluloid. Detailed color notes are taken of the specimen before they fade, and a plaster mold is then made. Liquid celluloid of the proper color is painted in the mold until the correct color pattern is worked out, a reinforcement of papier-maché or wax is put in, and when it is dry the mold is taken off. The resulting cast is cleaned with water and is ready for exhibition. By this process, extremely lifelike specimens can be produced, but the method is most exacting and requires a most intimate knowledge of both subject and materials.

**Fish.** Most museums use plaster casts of fish in their exhibits. In preparing these casts, the specimen is first washed thoroughly to remove the mucus with which most fish are covered. A plaster mold is then made of the better side and as soon as the plaster is set it is removed. The fins and tail are cut off and dried between cardboard. Any air bubbles or other imperfections in the mold are filled with fresh plaster mixed with water. Salad oil is then brushed on the inner surface to act as a separator, and liquid plaster-of-Paris is poured into the mold. When this has hardened, the mold is soaked in water and broken off the cast. The dried fins and tail are fastened on the cast when it is dry. Artificial glass eyes are set in their proper positions by cutting depressions in the cast, and hot wax is used to fill in around the eye. The cast is then covered with thin white shellac. When this is dry, the natural colors are restored with oil paints. It is very important that color notes be made as soon as the fish is removed from the water. Even then, some of the delicate colors will be lost.

If the skin is to be mounted, a plaster mold is made of one side as before. The skin is taken off by making an incision in one side of the fish, and by careful handling the body can be taken out of the skin without loosing the scales. The skin is degreased in carbon tetrachloride, poisoned in arsenic solution, and replaced in the plaster mold. Papier-maché is worked into the skin while it is in the mold, and the skin of the back of the fish is given its proper shape. When the maché is hard, the fish is taken out of the mold and any flaws are touched up. The fins and tail are clamped between cardboard, and the specimen is set away to dry. Artificial eyes are set in place and any deficiency is repaired in wax. The specimen is then given a coat of thin shellac, and the colors are restored, using the color notes as a guide. If the fish is to look wet, as it does on being taken from the water, it must be given a coat of varnish.

**Crabs, Crawfish, and Lobsters.** In mounting crabs, crawfish, or lobsters, careful color notes are first taken. The top shell is then pried loose from the section containing the legs, and a core resembling that containing the legs is built, using excelsior bound with thread. The legs are taken off and cleaned, poisoned, wired, and fastened back on the excelsior body, as is done with birds. A little maché is worked into the shell and over the excelsior body, and the shell is then worked down over the body until it is in its proper position. The natural eyes are left in specimens of this type. Wires are used in the long feelers of the lobster, and sections of the large claws may be cut out on the side that is near the base to help remove the flesh from these parts. The specimen is then posed on the base it is to occupy and allowed to dry for a week or two before the colors are restored in the usual manner. G. A.

**TAY,** the longest river in Scotland. In its course of 120 mi. from the source of its remotest headstream, the Tummel, it flows from Loch Tay in Perthshire in a general east-southeast direction into the Firth of Tay. With its tributaries, the Earn, the Almond, the Isla, the Tummel, and Loch Ericht, the Tay drains a basin of over 2,400 sq. mi., and has the largest volume of water of any river in Britain. It is famous for its salmon fisheries. S. Van V.

**TAYLOR, BAYARD** (1825-1878), American journalist, lecturer, and man of letters, was born in Kennett Square, Pa., Jan. 11, 1825. As a special correspondent he traveled widely. Records of his journeys are included in the books *Views Afoot* (1846), *Eldorado* (1850), *A Journey to Central Africa* (1854), *The Lands of the Saracen* (1854), *A Visit to India, China, and Japan in the Year 1853* (1855), *Northern Travel* (1857), *Travels in Greece and Russia* (1859), *Colorado, A Summer Trip* (1867), and *Egypt and Iceland in the Year 1874* (1874). After 1854 he was popular as a lecturer. When the Civil War began, he became head war correspondent for Horace Greeley's New York *Tribune,* covering Washington and the front. In 1878 he was made Minister to Germany, where he died, Dec. 19, 1878.

Taylor achieved fame in his own day as a poet as well as a journalist. His *Poems of the Orient* (1854) influenced T. B. Aldrich and R. H. Stoddard. He wrote four novels, *Hannah Thurston* (1863), *John Godfrey's Fortunes* (1864), *The Story of Kennett* (1866), and *Joseph and His Friend* (1870). His translation of Goethe's *Faust* (1870-1871) is still regarded as standard and is his best-known work. S. E. G.

**TAYLOR, JEREMY** (1613-1667), English clergyman and religious writer, was baptized Aug. 15, 1613, at Cambridge, where he later attended Perse Grammar School and Gonville and Caius College. In 1633, after taking Holy Orders, he substituted for a friend as preacher at St. Paul's Cathedral in London and there attracted the attention of Archbishop Laud, who became his patron. After serving for a time as chaplain to Laud and to Charles I, he became rector of Uppingham, Rutlandshire, and in 1639 was married. In 1642 he received the degree D.D. at Oxford, and in the following year the king presented to him the rectory of Overstone, Northamptonshire. During the civil wars he was chaplain to the king's household until he was captured in the royalist defeat at Cardigan Castle in 1645. Later he retired to Golden Grove, Carmarthenshire, in Wales, where he was chaplain to the Earl of Carbery. His wife died in 1651 and he remarried shortly thereafter. He made occasional trips to London and was several times imprisoned by the officers of the Commonwealth. In 1658 he accepted a lectureship at Lisburn in Ireland. Although he hoped to return home at the Restoration, he was appointed bishop of Down and Connor and administrator of Dromore in 1661. He soon became a member of the Irish privy council and vice-chancellor of the University of Dublin. In all these positions he strove to improve a situation made difficult not only by the enmity of the Roman Catholics, but also by the jealousy of the Presbyterian clergy. He died at Lisburn, Aug. 13, 1667, and was buried in the cathedral of Dromore.

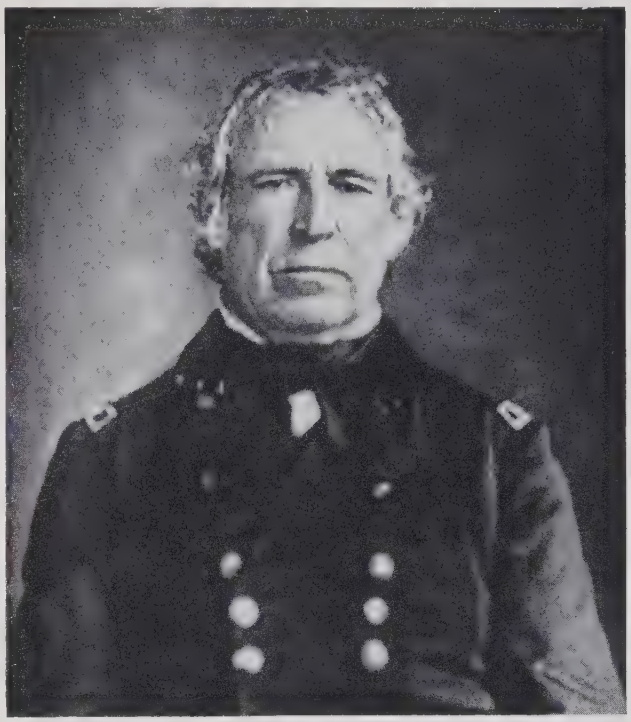
Taylor wrote voluminously on a number of religious subjects. The works on theology and on current ecclesiastical disputes lack abiding value, but there are others that by their matter or, more frequently, their manner have earned a place in literary history. *A Discourse of the Liberty of Prophesying* (1646) is a remarkable plea for toleration, reducing essential Christianity to belief in the Apostles' Creed and a good life. The most popular of Taylor's writings, however, have been *The Rule and Exercises of Holy Living* (1650) and *The Rule and Exercises of Holy Dying* (1651). Both are practical manuals of devotion and conduct, and *Holy Dying* is colored by sincere emotion. Today they are read almost exclusively for enjoyment of their rich style, not elaborate, but yet the product of conscious artistry. The same qualities are present in Taylor's sermons. H. B. W.

**TAYLOR, (JOSEPH) DEEMS** (1885- ), American composer, critic, and author, was born in New York City, Dec. 22, 1885. In his varied career, he has been a war correspondent, music teacher, translator, music critic, editor of *Musical America,* author of two books on music, narrator for the Metropolitan Opera broadcasts, commentator for the New York Philharmonic broadcasts, and moderator for Walt Disney's *Fantasia* (1940). In 1942 he was elected president of the American Society of Composers, Publishers, and Authors and was later musical adviser to the Columbia Broadcasting System. His most important works include three operas, *The King's Henchman* (1926), *Peter Ibbetson* (1930), and *Ramuntcho* (1937); the orchestral suite *Through the Looking Glass* (1918); two cantatas; several songs and choral works; and his *Elegy* for orchestra (1944). D. L. E.

**TAYLOR, THOMAS** (1758-1835), English scholar and translator, was born in London on May 15, 1758. Educated haphazardly for the Dissenting ministry, he became a bank clerk after an imprudent marriage, but continued his interest in metaphysical speculation. About 1785 he attracted attention by his exhibition of a "perpetual lamp" and by lectures on Plato; later he secured patronage which permitted his devotion to study until his death, Nov. 1, 1835, at Walworth. He published more than fifty volumes of translations, most of them the first in English, of works by Plato, Aristotle, Pausanias, Plotinus, Proclus, and minor esoteric Classical writers. In lengthy commentaries he interpreted these authors in the mystical and allegorical neo-Platonic fashion, and enthusiastically expounded vegetarian and polytheistic doctrines. Although frequently ridiculed, Taylor had numerous readers in England and America, among them Coleridge, Wordsworth, Shelley, Emerson, and many theosophists. Uncritical and inferior in scholarship, his work nevertheless marks the beginning of modern popular interest in Platonism. F. B. E.

**TAYLOR, ZACHARY** (1784-1850), twelfth President of the United States, was born in Orange County, Va., on Nov. 24, 1784, the third child of Colonel Richard and Sarah Strother Taylor, both of English ancestry. Not long after his son's birth, the elder Taylor moved to Jefferson County, Ky., where he was appointed collector of customs at the port of Louisville by George Washington. Richard Taylor, who had served in the American Revolution, soon became an influential man in this frontier community, acquiring a large plantation and representing his county in the state legislature. Taught by a private tutor, Zachary received only an indifferent education, but he gained practical experience from helping to run the family plantation. The life of a farmer apparently did not appeal to him, however, for at the age of twenty-four he accepted a commission as lieutenant in the United States Army. He was made a captain in 1810, and in that year married Margaret Mackall Smith of Maryland.

**Military Career.** Taylor followed his military career for nearly forty years, spending most of this time at various frontier posts protecting the advancing settlements from the Indians. During the War of 1812 he served with distinction



FABIAN BACHRACH

*ZACHARY TAYLOR, TWELFTH PRESIDENT OF THE UNITED STATES*

under Gen. William Henry Harrison and was brevetted a major. After the war he retired from the army when his rank was reduced, but returned two years later when he was offered a regular army commission as major by President James Madison. Thereafter he participated in the Black Hawk War (1832) and in putting down the Seminole insurrections in Florida (1837-1840), acquiring the nickname "Old Rough and Ready." In 1840 Taylor was placed in command at Fort Jesup in Louisiana. Settling his family at Baton Rouge, he purchased a plantation on the Mississippi River with the intention of combining his army career with the life of a planter, but this venture was unsuccessful, largely because of seasonal floods.

Taylor's opportunity came with the Mexican War. Ordered to guard against a possible Mexican invasion following the Texas annexation, he set out with 4,000 men in July 1845 and took up a position at Corpus Christi, at the mouth of the Nueces River. Early in 1846, on orders of President James K. Polk, he advanced to the Rio Grande, where he built fortifications across from the Mexican town of Matamoros and waited for an "overt act." This occurred when the Mexicans ambushed a scouting detachment of cavalry, and resulted in a declaration of war by the United States. Receiving reinforcements, Taylor met and defeated the Mexicans at Palo Alto and at Resaca de la Palma, north of the Rio Grande. He then crossed the river into Mexico, occupied Matamoros on May 18, and advanced southward to take the fortified town of Monterrey on September 23. By the end

of the year Taylor, with about 10,000 men, was holding a 200-mile line in northern Mexico. Instead of continuing his advance, however, he was ordered to release half his force for the major assault to be launched by Gen. Winfield Scott against Veracruz and the heart of Mexico. Despite his reduced command, Taylor was victorious in his final engagement of the war, Feb. 22-23, 1847, when he defeated Gen. Santa Anna's numerically superior but poorly led Mexican army at Buena Vista. This battle made Taylor a national hero, but he was a Whig and the Democratic administration was none too enthusiastic about his growing popularity. After the Battle of Buena Vista he was ordered to discontinue his invasion of Mexico. He had already accomplished enough to capture the public fancy, however, and was advanced as a candidate for the Whig presidential nomination in 1848 by the New York politician Thurlow Weed.

**Presidency.** In the campaign of 1848 Taylor's lack of a political past proved an asset, but his blunt statements on public policy and his assertions that he would not be a president dominated by his party worried the Whig politicians. His public popularity, however, forced his nomination on the fourth ballot over Henry Clay, Daniel Webster, and Winfield Scott. Largely because Martin Van Buren split the Democratic Party in New York, Taylor won that state, and thus the election, over his opponent Lewis Cass. His administration started inauspiciously, with neither his inaugural address nor his cabinet appointments stirring popular support. The President's lack of political experience was soon apparent, especially when he delayed making changes in his cabinet even after its integrity was compromised by the involvement of several members in a money scandal. On the other hand, he was courageously honest and sought to do what was best for the nation. His efforts toward this end were nowhere more evident than in his handling of the slavery question which had been uppermost in the country's mind since the introduction of the Wilmot Proviso into Congress in 1846. Although Taylor was a slaveholder and the one-time father-in-law of Jefferson Davis, he was remarkably impartial in dealing with this delicate issue. Assuring the South that it need not fear any attacks against slavery where then existing, he also let it be known that he would meet any overt acts of the South with force. Later he advised the territories of California and New Mexico, which opposed slavery, to seek statehood and recommended their admission to Congress provided their governments were republican in form. Moreover, he sought to curtail the ambitions of Texas for more extensive boundaries, even to the extent of military occupation of the disputed area as a part of the Federal domain until disposed of by Congress. He thus incurred the bitter opposition of many of his Whig supporters in the South, but he did not live to see the working out of the Compromise of 1850. On a hot July 4, 1850, he became critically ill from exposure to the heat and imprudent eating, and died on July 9. He was buried near Louisville, Ky. *See also* MEXICAN WAR. G. E. M.

**TAYLOR,** a borough in Lackawanna Co., in northeastern Pennsylvania, situated on the north bank of the Lackawanna River, 4 mi. southwest of Scranton. It is a suburb of Scranton, located in the anthracite-coal region, and coal mining is its major activity. It was founded in 1790 and incorporated in 1893. Taylor was named for Moses Taylor, an early railroad promoter. The borough is governed by a mayor and council. The Delaware, Lackawanna & Western Railroad and the Central Railroad of New Jersey provide transportation. Pop. 1950, 7,176.

**TAYLOR,** a city in Williamson Co., in east central Texas, situated 35 mi. northeast of Austin. It is a trading center for a cotton-raising area. Taylor was settled in 1876 and incorporated in 1890. It is governed by a council and city manager. Kenney's Fort, 3 mi. away, was the rendezvous of the ill-fated Santa Fe Expedition of 1841 when Texas attempted to extend its jurisdiction to New Mexico. Taylor is served by the Missouri-Kansas-Texas and the Missouri Pacific railroads. Besides its chief industries, which produce cotton and cottonseed oil, the city has a bedding factory, flour mills, iron and machine works, and meat-packing, cold-storage, and frozen-food locker plants. Pop. 1950, 9,071.

**TAYLOR'S SERIES.** *See* FUNCTION.

**TAYLORVILLE,** a city in central Illinois, the county seat of Christian Co., situated 27 mi. southeast of Springfield. Coal is mined in the area, and grain is the region's chief crop. Taylorville was founded in 1839 and incorporated in 1882. The city is governed by a mayor and council. A stone slab commemorates the services of Abraham Lincoln in the Taylorville courthouse. The city is served by the Baltimore & Ohio, the Wabash, and the Chicago & Illinois Midland railways. The city has hatcheries, and its manufactures include paper, stationary, greeting cards, cigars, feed and tools. Pop. 1950, 9,188.

**TAYMYR (DOLGANO-NENETS) NATIONAL OKRUG** [taimɪ'r; tai'mɪr], an administrative unit comprising the northern part of the Krasnoyarsk Krai in the central Siberian region of the Russian Soviet Federated Socialist Republic in the Soviet Union. The okrug, organized in 1930 with an area of 316,293 sq. mi., consists for the most part of a peninsula projecting into the Arctic Ocean between the Kara and Laptev seas and extending to Cape Chelyuskin, the northernmost point of the Asiatic mainland. Because the base of the Taymyr Peninsula merges into the Northern Siberian Lowlands, the highest elevations are attained in the north in the Byrranga Plateau, a ridge of folded Paleozoic rocks 984 to 1,640 ft. above sea level. The descent to the northern shore is gradual, the land being covered with a moraine, and numerous beach ridges and inland marine debris indicate a coastline still in the process of being uplifted. There are many indentations, but only those at the mouths of the Yenisey and Khatanga rivers are large. South of the Byrranga Plateau, which runs from southwest to northeast for 625 mi., are many scattered lakes, the two largest being Taymyr and Pyasina; the former is the largest lake in the Arctic.

Lying mostly north of the Arctic Circle, the entire Taymyr Okrug is in the tundra zone, but the aridity associated with high latitudes means that there are fewer swampy areas than there are farther south. The vegetation is interspersed with patches of bare rock. At Cape Chelyuskin the temperature ranges from —23° F. in December to 35° F. in July. The population of the okrug consists of a scattering of Nenetses (Samoyeds), Tunguses, and Dolgans (Nganasans), who exist on the reindeer, wolves, polar bears, lemmings, ermine, and migratory birds that inhabit the district. The Nenetses observe a type of transhumance, driving their reindeer herds to the Byrranga Plateau in the summer and retreating farther south in the winter along the Pyasina and Khatanga rivers. Dudinka on the Yenisey is the administrative center of the district and a port of call on the northern sea route. A short railroad runs east from Dudinka to Norilsk, and from Norilsk a winter trail runs overland to

Khatanga and Nordvik to the northwest. Little geologic work seems to have been conducted in the region, but it is known that there are many salt domes, particularly near Khatanga Bay. Those at Nordvik produce excellent salt. Traces of sulphur and petroleum have been reported, and along the Taymyr River are deposits of gold and graphite. Pop. (est. 1954), 30,000. W. S. V.

**TBILISI** [tpɪ'lɪsɪ], formerly Tiflis, a historic, commercial city and the capital of the Georgian S.S.R., in the southwest Soviet Union, 270 mi. northwest of Baku. It lies on both banks of the upper Kura River at 1,350 ft. above sea level in a mountain-ringed basin of the Caucasus Mountains. Though the actual origins of Tbilisi are obscure, it seems to have begun in the fourth century in the vicinity of several hot mineral springs. In the fifth century the capital of Georgian rulers was transferred from Mtskhet to the town. Located as it was on one of the world's great crossroads of invasions and migrations, it was repeatedly assaulted and plundered during the seventh, eighth, and ninth centuries by Persians, Greeks, and Arabs. It was completely devastated in 828 by the Khazars. Pillaged later by Turks, it was taken by the Mongol conqueror Tamerlane in 1387. When Persia attempted to take the city in 1795, Georgia accepted Russian "protection" and was annexed by Russia in 1799. Tbilisi remained the seat of the tsarist government in the Caucasus from 1801 to 1918, and it was a White Russian stronghold during the civil war following the 1917 Revolution. Joseph Stalin was born near Tbilisi in 1879.

The town is compared with Cairo in its contrasts of the old and the new and its extremely cosmopolitan atmosphere. The busy, colorful market section and bazaars are a mixture of many peoples and tongues. The Zion cathedral dates from the fifth century. Institutions include a state university, academy of sciences, institute of medicine, museum, theatre, and schools of agriculture, forestry, industry, technology, art, and music. Tbilisi is the southern terminus of the famous Georgian military road over the Caucasus Mountains from Dzaudzhikau, and it also is located on the southern Black Sea-Caspian railway. As the agricultural and economic center of the Transcaucasian region it has a large trade in a variety of items. A hydroelectric station on the Kura near the city furnishes power to the city's numerous industries, whose manufactures include textiles, shoes, clothing, silk, lumber, paper, furniture, chemicals, film, cottonseed oil, margarine, machines, oil industry equipment, tobacco products, leather goods, tapestry, and distilled spirits. Pop. (est. 1954), 580,000. C. C. H.

**TCHAD LAKE.** *See* CHAD LAKE.

**TCHAIKOVSKY, PYOTR ILYICH** [tshaikɔ'fskɜɪ; tshaikɔ'fski] (1840-1893), the most famous of all Russian composers, was born May 7, 1840, at Votkinsk, the second child of five sons and a daughter of music-loving parents. Tchaikovsky's musical ability manifested itself early, and when he was less than five years old he composed with his older sister a song about his mother; a few months later his governess started him in his first music lessons. As a child Tchaikovsky was sickly and extremely sensitive; he was also intensely affected by music. His parents, however, wished him to become a lawyer, and at the age of ten he was placed at a school in St. Petersburg in preparation for his enrollment at the law school in the same city two years later. At the same time, however, he continued his study of music. Immediately on graduating from law school Tchaikovsky was appointed a clerk in the Ministry of Justice, where he remained from his nineteenth until his twenty-third year. But music came to dominate him more and more, and after a European trip on which he visited Berlin, Antwerp, Brussels, London, Paris, and other cities, and as a result of his serious lessons in harmony with Nikolai Zaremba, he became convinced that he was to be a composer and entered the St. Petersburg Conservatory at the age of twenty-two. Tchaikovsky spent three years at the Conservatory, leaving the Ministry of Justice and supporting

PYOTR ILYICH TCHAIKOVSKY

FROM A DRAWING BY LOUIS LUPAS

himself by teaching piano and theory; his teachers here were Anton Rubinstein in composition and orchestration, and Zaremba in harmony and counterpoint. After his graduation Tchaikovsky was engaged by Nikolai Rubinstein, the brother of Anton, as professor of harmony at the Moscow Conservatory. During that year he added a major work, the First Symphony, to the numerous shorter compositions he had already written for piano, voice, chorus, and ensembles.

Tchaikovsky's nearly twelve years as a teacher at the Moscow Conservatory were most eventful. During this time he fell in love with Désirée Artôt, a French opera singer appearing in Moscow, only to be jilted by her. He also became a music critic for a Moscow newspaper, a position which he held for several years, and visited the Wagner Festival at Bayreuth, meeting Franz Liszt and endeavoring to see Richard Wagner there. His singular friendship with Nadezhda von Meck, who aided him financially and whom he never met, dates from this period, as does his marriage. This marriage, doomed from the start by Tchaikovsky's sexual abnormality, proved a disastrous experience and, though it lasted only a few months, it drove the composer to attempt suicide. In spite of extreme spiritual suffering and overwhelming material hardships during most of this turbulent period, however, Tchaikovsky wrote a considerable amount of music, including some of his greatest works. To these years belong the first four symphonies; the First Piano Concerto, originally dedicated to Nikolai Rubinstein, but after Rubinstein's severe criticism of it rededicated to Hans von Bülow; three string quartets; five operas, the last of which was *Eugene Onegin,* his best-known opera; the ballet *Swan Lake;* and much other music.

Through the generosity of Mme von Meck, Tchaikovsky was freed from all financial worries at the age of thirty-seven; he resigned his position at the Conservatory in the following year and until his death was able to concentrate solely upon composition. His development as a composer was slow, and fame for many years eluded him, but he was

a hard and systematic worker and produced a large variety of compositions each year. Financially independent, Tchaikovsky was also able to travel in European countries and on such trips his restless nature was temporarily calmed. His independence also provided him with the opportunity to study conducting, and he made his first appearance as a conductor in a concert of his own works in St. Petersburg at the age of forty-seven. His success in this concert was a surprise to him, for he believed he possessed no talent for conducting, but it led to an engagement for a European tour the following year. On this tour, Tchaikovsky appeared with great success in Paris, Berlin, Leipzig, Prague, and elsewhere, conducting, as before, only his own works, but his nervous temperament and retiring nature, in addition to the inconveniences of a pressing schedule, permitted him but little satisfaction from the tour. Far more important to him was his acquaintance with most of Europe's famous musicians, among them Brahms, Gounod, Massenet, Busoni, Paderewski, Grieg, Dvořák, Fauré, and numerous others.

At forty-eight, Tchaikovsky composed one of his most popular symphonies, the Fifth, and in the next year completed his second ballet, *The Sleeping Beauty,* which at first was not successful. During this period of financial independence, he also composed several other works which have since helped to establish his fame, among them his overtures, *Romeo and Juliet* and *1812,* and the popular *Nutcracker Suite.* In 1890 his friendship of fourteen years with Mme von Meck, maintained by mutual agreement solely through a voluminous correspondence, was ended abruptly by her, for reasons which remain mysterious. In the same year he finished his ninth opera, *The Queen of Spades.* Shortly afterwards Tchaikovsky visited America and at the invitation of Walter Damrosch came to New York in 1891 to conduct the New York Symphony Society Orchestra at the festival concerts inaugurating Music Hall, now Carnegie Hall. He also conducted in Baltimore and Philadelphia. Tchaikovsky enjoyed his short stay in the United States, but he departed for Russia in an exhausted condition brought on by what for him was the too-fast tempo of American life. In 1893 Tchaikovsky began work on his most famous symphony, the Sixth or *Pathétique.* It was also to be his last; while he was still working on it, he traveled to England to receive an honorary degree from Cambridge University, but shortly after his return to Russia and the completion of the symphony, Tchaikovsky died of cholera in St. Petersburg, Nov. 6, 1893. W. La.

**TCHEKHOV, ANTON PAVLOVICH.** *See* CHEKHOV, ANTON PAVLOVICH.

**TCHELITCHEW, PAVEL** [tshɛ'lɪtshɛf] (1898- ), Russian painter and stage designer, was born in Moscow on Sept. 21, 1898. After escaping from Moscow at the time of the Russian Revolution, he received his chief training in art while living in Kiyev between 1918 and 1920. After sojourns in Odessa, Constantinople, and Sofia, he arrived in Berlin by 1921 and soon won acclaim as a stage designer. In 1923 he went to Paris, where he remained until 1934, when he established himself in the United States.

Tchelitchew began his career under strong influence from the abstract schools of painting. In Kiyev he was associated with Alexandra Exter, a pupil of Fernand Léger, and he studied under Bogomazov, a Cubist, as well as under the Constructivist stage designers Rabinovich and Tchakrigine. His experience with these artists never ceased to serve him as discipline in matters of structural analysis, but he soon adopted a representational approach in his work. By 1926 he had evolved a mature style, and in the same year, with Eugène Berman and Christian Bérard, he launched the Neo-Romantic movement, which embodied a program designed to restore allusive and humanistic content to painting.

Tchelitchew's subsequent production is characterized by an acutely imaginative examination of reality, which, as in the *Head of Gold* (Edward James Collection), seeks to uncover new psychological and visual aspects of man and nature. His color is rich and sensuous, with warm tints in predominance, and his light is unearthly in its penetrating radiance and luminosity. These qualities are especially well displayed in *Hide and Seek* (Museum of Modern Art, New York). In some of Tchelitchew's paintings, multiple images are laid kaleidoscopically in single dominant forms, and the elements of composition are seen from different points of view and in distorted perspective, as in *The Clown* (Sherman Kent Collection, Washington, D. C.). Thus his work constantly reveals not only extreme fantasy, but a daringly original vision coupled with unusual mastery of structural design. M. J.

**TEA,** a beverage derived from the leaves of *Thea sinensis,* a member of the tea family. Tea drinking has increased for sixteen centuries until today it is the most widely drunk hot beverage. Annual production approximates 2,000,000,000 lb. The leaves contain 1 to 3 per cent caffeine (theine) and a little theophylline. Weight for weight, tea leaves have more than twice as much caffeine as coffee beans, but a cup of coffee generally has more of the alkaloid than a cup of tea. One pound of tea leaves furnishes about 250 to 300 cups whereas one pound of coffee makes only 40 cups. Powdered, instantaneous tea, and compressed tea tablets are recent forms of tea on the American market.

**Botany.** Tea is an evergreen plant 15 to 20 and sometimes 30 ft. high in the wild state. It is indigenous to Assam and parts of China and Japan. Profusely branched, it bears very numerous alternate, elliptical or lanceolate, short-stemmed leaves, 2 to 5 in. long at maturity. The leaves have serrate margins, and the flowers are white, slightly fragrant, and about one inch across the widely spread, deeply cut corolla lobes, of which there are five to nine. The fruit is a woody capsule containing a globose seed in each cavity.

**History.** According to legend, a Chinese philosopher discovered the tea beverage when leaves fell into his campfire pot of boiling water and sent up a delicious aroma. It was introduced into Continental Europe by the Dutch in 1610, and into England in 1664. London is the tea capital of the world, and the average Briton drinks five cups a day. Tea was first sold in Boston in 1714 and in New York in 1728. Tea culture began in China in prehistoric times, in Japan in the Middle Ages, and in India and Ceylon about 1870. In the 1880's tea was grown successfully in North Carolina and Texas, but abandoned because of the labor cost. Before World War II tea was cultivated on large areas in China, Ceylon, Formosa, India, Japan, Java, Pakistan, and Sumatra. Since World War II it has been grown commercially also in Australia, Bolivia, Brazil, Guatemala, New Guinea, Peru, the Soviet Union, and South Africa.

**Agriculture.** Tea is grown in open fields or on terraced hillsides. The plants are kept pruned to bush size except the seed trees, which are allowed full natural growth. Numerous varieties have been produced through long cultivation. In the Orient the plant thrives best under a rainfall of 90 to 200 in. a year. It prefers a warm climate (50° to 90° F.) at moderate altitudes. Acid soil, pH 4.5 or less and not

over pH 5.57, produces the best growth. Plants are pruned slightly each year, but drastically in the spring of the third year, and collar-pruned (almost to the ground) in the tenth year. This results in suckers sprouting up from underground and produces a large bush with several main stems; such a plant yields a crop every forty days. The average life of a tea plant is twenty-five to fifty years.

**Production and Trade.** Of the 2,000,000,000 lb. of tea produced annually, China is the leading producer (700,000,000 lb.). India is the leading exporter (322,000,000 lb.), but second in production; Ceylon is third in production. Following India in export volumes are the East Indies (150,000,000 lb., second); China (100,000,000 lb., third); Japan (40,000,000 lb., fourth); and Formosa (20,000,000 lb., fifth). The United Kingdom buys 440,000,000 lb., leading the world in importation. The United States imports 90,000,000 to 100,000,000 lb.; Australia, 50,000,000 lb.; the Soviet Union, 45,000,000 lb.; and Canada, 40,000,000 lb. South Africa supplies itself with only one twentieth of its tea requirements and imports large quantities. Small amounts are produced in other geographic areas.

**Harvesting and Processing.** The first profitable "flushing" (complete picking) occurs in the fifth year. Native pickers pluck the bud and the first two leaves of all twigs on the bush. This procedure constitutes fine plucking and yields the finest tea. If the third leaf is tender, it is plucked off at the same time. This is medium plucking. When the fourth leaf is included, it is coarse plucking.

Leaves for black tea (fermented) are spread on withering racks (chungs) to allow proper oxidation. Then the leaves are rolled to break cells without tearing leaves badly. This allows further oxidation after which the leaves are dried (fired) in baskets over charcoal fires or in tea-firing machines in modern buildings. Oolong tea is semifermented; and leaves for green tea (unfermented) are steamed (panned) to stop fermentation.

"Pekoe" is Chinese for "white hair" and referred originally to the youngest leaves covered with down. Orange pekoe was formerly scented with orange blossoms in China. Today, pekoe is a commercial grade which results from sifting, after firing, through a sieve with a certain sized mesh. Orange pekoe is a better grade than pekoe. Souchong is a poorer grade than either pekoes.

Principal kinds of Indian tea in northern India are Assams, Darjeelings, and Dooars. In Ceylon the types are high-grown, medium-grown, and low-grown teas. In China the classification is China greens, China blacks (Congous), and Oolongs, scented and compressed. North China varieties are blacks (Keemuns, Ningchows, Ichangs), Burgundies, and South China blacks (Congous, red leaf Congous, Kaisows, and Foochows). The clarets are Chinese teas. Netherland Indies teas are black teas known as Java and Sumatra, with exports also bearing the name of the tea garden source. Brazilian tea types are equivalent to broken orange pekoe, orange pekoe, pekoe, and broken tea.

Professional tea-tasters can identify the source (country and district) and sometimes even the season in which the leaves were picked. Tasters sip but seldom swallow tea. Americans depend upon the taste sense of fewer than forty men as the guide for wise purchasing and blending of imports each year to maintain uniformity in the brands on the market.

**Miscellaneous Uses.** Tea leaves were first used as a vegetable relish, and are still pickled and so used in Burma. Chinese women press tea leaves into solid blocks for export by camel caravan to the interior of Mongolia, where brick tea is stewed in water until softened and then eaten with butter or with *tsamba* (ground, parched wheat or barley). Certain Mongolian tribes add a pinch of salt to beverage tea. Tea is a part of religious ceremonial rituals in China and Japan. Taoists include it in an elixir of immortality, and Buddhists consume it during meditation hours. Cake-tea has been made in China since before the T'ang Dynasty (618-907). Steeping tea, the general practice today, was developed during the Ming Dynasty (1364-1644). In Japan white jasmine flowers, called "Mokle," are added to make the commercial "jasmine tea." In Siam tea leaves are chewed. Arabs flavor their tea with mint and this mixture is available on the American market. Most commercial caffeine is extracted from tea waste and sweepings; it is used in medicine and in the soft drink industry. R. H. C.

**TEACHERS COLLEGE,** a college offering professional courses for teachers and administrators of all grades and all departments of the United States educational system, from nursery school through the university. Founded in 1888 and chartered by the Regents of the University of the State of New York in 1889, Teachers College became a part of Columbia University in New York City in 1897, although maintaining its separate corporate organization.

Programs may be planned leading to the B.S., the M.A., the M.S., the Ed.D., or the Ph.D., conferred by Columbia University. The courses offered by Teachers College are organized under four divisions: foundations of education, administration and guidance, instruction, and nursing education. In addition the college offers interdivisional programs of study in such fields as community service, group work, religious education, intergroup relations, communication arts, co-operative extension service, education for marriage and family life, and recreation. Teachers College maintains a bureau of publications to make available the research studies of its faculty, staff, and doctoral candidates. The bureau also publishes the *Teachers College Record,* teacher reference materials, tests, yearbooks, monographs, films, and syllabuses.

Dormitory and dining facilities are provided. For students not living in the college residence halls, furnished rooms and apartments in the neighborhood are available. Fellowships, scholarships, and loan funds are offered. Opportunities for self-help are available in many fields. *For statistics see* COLLEGES AND UNIVERSITIES. J. R. To.

**TEAK,** a tall, stately forest tree, *Tectona grandis,* of the verbena family, renowned for its excellent and durable timber. It is a native of southeastern Asia; commercial supplies of teak lumber come from India, Burma, Siam, and Java. Much of the timber has been depleted by cutting. The tree, which grows to a height of 100 to 150 ft. and has a trunk 3 to 8 ft. in diameter, bears large, oval, deciduous leaves, numerous white or bluish flowers in terminal clusters, and globular fruits about the size of cherries, containing oily seeds. Teak wood is hard, heavy, and strong, and the brown heartwood is nearly immune to decay. Its shrinkage in drying is very small, close to that of mahogany, and it is used in the United States and Europe chiefly for the decking of large and expensive vessels; for cabin interiors of small pleasure boats, ships, and yachts; and for the interior finish of fine residences, club rooms, and bank buildings. W. D. B.

**TEAL,** a name loosely applied to almost any small (14 to 17 in.) species of river duck. There are about fifteen species widely distributed throughout the world. The best known is the common green-winged teal, *Nettion carolinense,* a beau-

tiful species with green and chestnut head and a conspicuous patch of metallic green on the wing. It breeds in temperate regions around the Northern Hemisphere and is found in winter in most parts of the United States. Two other birds known in America as teal, but more properly called blue-winged ducks, are the blue-winged teal, *Querquedula discors,* and the cinnamon teal, *Q. cyanoptera.* The former closely resembles a diminutive shoveler; the latter is chestnut, with a sky-blue wing patch. Teal are vegetarian ducks and occur in large flocks where food is plentiful. They are favorites with sportsmen because of their rapid rise from the water and their swift flight. H. G. De.

**TEANECK,** a township in Bergen Co., in northeastern New Jersey, situated on the Hackensack River, across the river from Hackensack. The first land grants including the township's site were issued by the Dutch government, and in 1669 the English government included the same territory in a grant to Captain John Berry. The majority of the early settlers were Dutch and French Huguenots. The community, which includes West Englewood, became an independent township in 1895. Local government is administered by a manager, mayor, and council. Transportation is provided by the West Shore division of the New York Central System. It is a strictly residential community, whose residents commute to work in the surrounding industrial cities of New Jersey and in New York City, 12 mi. distant. Pop. 1950, 33,772.

**TEA OIL TREE,** a small evergreen tree, *Camellia sasanqua,* of the tea family, bearing attractive flowers and shining leaves much like the cultivated *C. japonica.* Native to China and Japan, it is grown for its seed, which yields an oil similar to olive oil. *See also* Camellia. R. P. T.

**TEASDALE, SARA** [ti′zdel] (1884-1933), American poet, was born Aug. 8, 1884, in St. Louis, Mo. After private schooling and a period of travel in Europe and the Near East, she settled in Chicago. There she married Ernst B. Filsinger in 1914, but divorced him in 1929 and later moved to New York. There, except for visits to France and England, she lived until her death, Jan. 29, 1933.

Primarily a lyric poet, interested chiefly in committing personal emotions to verse, Teasdale adhered to no school and was little affected by contemporary currents of revolt and experimentation in poetry. Her unmistakably feminine lyrics frequently resembled those of Christina Rossetti, whom she greatly admired, and this similarity may be traced in her most familiar works: *Sonnets to Duse* (1907); *Rivers to the Sea* (1915); *Love Songs,* which was awarded the Columbia University Prize in 1917; *Flame and Shadow* (1920); *Dark of the Moon* (1926); *Strange Victory* (1933); and *Stars Tonight* (1930), a book of poems for juveniles. F. B. T.

**TEASEL** [ti′zəl], common name for a genus, *Dipsacus,* of stout, coarse, hairy or prickly biennials, which includes about 15 species native to North Africa, Asia, and Europe. Two of these species have become naturalized in North America. The European field teasel, *D. sylvestris,* is found in the eastern United States, where it has become widespread, while the fuller's teasel, *D. fullonum,* is grown to a limited extent in central New York for commercial purposes. The latter plant, when ripe, has flowering heads or "teasels" which are 3 to 4 in. long, cylindrical in shape, and densely beset with spiny, rigid scales; it grows to about 6 ft. tall. The heads are used in machines for raising the nap on cloth, a process called "fulling." For this purpose it is grown extensively in Europe. M. G. W.

**TEAZLE, LADY** [ti′zəl], the young and, at first, giddy wife of Sir Peter Teazle in the comedy *The School for Scandal* by Richard Brinsley Sheridan. By the end of the play she is reformed and reconciled to her husband. A. H. N.

**TECHNETIUM** [tɛknɪ′shiəm], symbol Tc, formerly called masurium, Ma, atomic number 43, at. wt. 99, the third member of Group VII-A, which includes manganese and rhenium. It was identified in the X-ray spectra of certain platinum and columbium compounds in 1925 by Noddack, who then discovered rhenium also. The artificial product was prepared at the University of California in 1937 by Perrier and E. Segrè by the bombardment of molybdenum with neutrons or deuterons. The name, which means artificial, was suggested by F. Paneth, and was adopted in 1947. H. N. A.

**TECHNOCRACY.** *See* Political Science and Philosophy (*Political Philosophy*).

**TECUMSEH** [tɪkʌ′msə] (c.1768-1813), Shawnee Indian chief, was born about 1768 in the valley of Miami, a few miles from Springfield, Ohio. As a warrior, he was opposed to savage acts, such as scalping, and had the reputation of keeping his word. In 1805, he and his brother resolved to form an Indian confederation to prevent further ceding of land to the American whites, and in 1810 he told William H. Harrison, Governor of Indiana, of his plan to wage battle if the lands were not restored to the Indians. Tecumseh obtained the support of the red men, and after Harrison had won the Battle of Tippecanoe, Ind. (Nov. 7, 1811), Tecumseh joined forces with the British in Canada in June 1812 and became a brigadier general. Oliver Hazard Perry's victory of Sept. 10, 1813, on Lake Erie made it clear to Tecumseh that the British intended to retreat eastward, but Tecumseh himself, unable to withdraw because of his fidelity to the men he had enlisted, remained and was killed at the Battle of the Thames, Oct. 5, 1813. W. E. A.

**TECUMSEH,** a town in Essex Co., Ontario, Canada, 5 mi. east of the city of Windsor, on Provincial Highway 39 and the Canadian Pacific Railway. It was incorporated as a town in 1921. Two-thirds of the inhabitants are of French origin. Pop. 1951, 3,543. D. F. P.

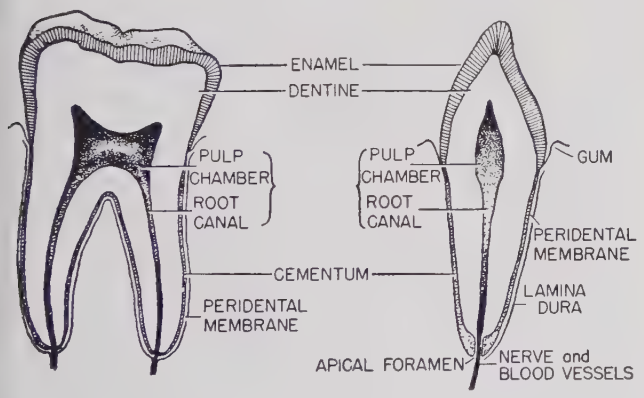
**TEDDER, ARTHUR WILLIAM (FIRST BARON TEDDER OF GLENGUIN)** (1890- ), British air marshal, was born in Stirlingshire on July 11, 1890, and was educated at Magdalene College, Cambridge, where he received his degree in 1912. On the outbreak of World War I in 1914 he was commissioned in the Dorsetshire Regiment but in 1916 transferred to the Royal Flying Corps; he became a permanent member of the Royal Air Force in 1919. In 1926, he was appointed to the Air Ministry, in 1929 he became a member of the directing staff of the R.A.F. Staff College, and in 1932 he was made commander of the Air Armature School at Eastchurch. From 1936 to 1939 he was air officer commanding the R.A.F. in the Far East and in 1939 became director general of research and development for the Air Ministry. In 1940 he was appointed deputy air officer commanding in the Middle East and, following the evacuation of Crete, was promoted to air officer in chief. He was Deputy Supreme Commander under General Dwight Eisenhower from 1943 to 1945 and was largely responsible

for the rout of the Germans and Italians in Tunis. In 1946 he received a peerage and was appointed Chief of the Air Staff and First and Senior Member of the Air Council. His publications include *The Navy of Restoration* (1915) and *Air Power in War* (1948). R. T.

**TEETH,** the hard, bonelike structures found in the mouth and used for the mastication of food. Each tooth has a crown, which projects from the gums; a root or roots, which are normally contained within a socket or alveolus; and a neck, which is a constricted portion between the root and the crown and is actually part of the root.

**Types of Dentition.** The teeth of man vary in shape from the incisors to the molars and are referred to as heterodont. Some mammals, such as the armadillo of South America and the dolphin, have teeth which are all alike in form. Man is equipped with two dentitions or sets of teeth (diphyodont). Animals like the rat have but one set of teeth (monophyodont), while the shark and crocodile may acquire many sets (polyphyodont). The first series of teeth in man is called the deciduous dentition and the second series the permanent dentition. The deciduous teeth are sometimes called the baby or milk teeth. They appear in childhood, approximately between the ages of six months and two and a half years. They begin to shed at the age of six years and are gradually replaced with the permanent dentition. Between the ages of six and twelve years there is a mixed dentition of deciduous and permanent teeth in the mouth.

**Types of Teeth.** The teeth arrange themselves in an arch which varies in different individuals. Those in the upper jaw are called the maxillary, and those in the lower jaw, the mandibular teeth. Based on original function, the teeth have been divided into three groups: the incisors, which are used primarily for cutting; the canines and premolars (bicuspids), which originally were used for the prehension of food and today function in a cutting capacity similar to the incisors; and the molars, which are used for grinding.

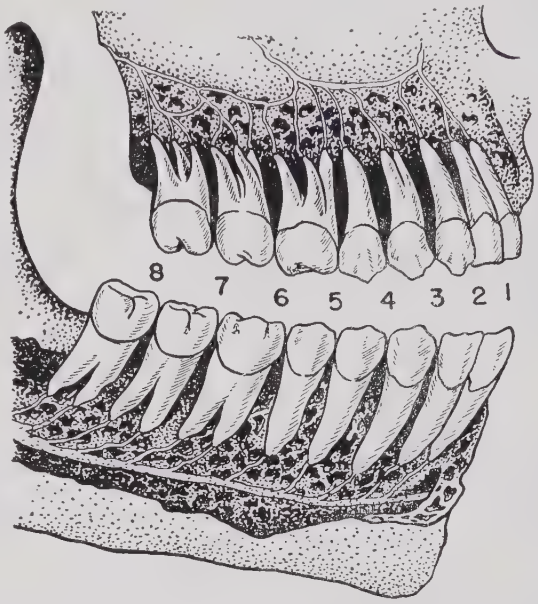


*Cross sections of two types of teeth.*

**Tooth Structure.** The bulk of the tooth structure is composed of dentine, which is covered by enamel on the crown and by cement on the root surface. Within the tooth is a space called the pulp cavity.

The enamel is a hard, dense substance composed primarily of inorganic material and a small amount of organic matter. Dentine, also a hard substance, though softer than enamel, is chemically very similar to bone. The pulp connects with the body through the openings at the end of the root canals, called the apical foramina. An artery, a vein, and a nerve pass through this foramen into the canal of the root and up through the canal to the pulp chamber located in the crown of the tooth.

The roots of the teeth are set in sockets or alveoli and are held in place by tiny fibers which connect with the cement covering the root surface of the tooth and the bone lining the socket. This filmlike tissue between the root and the socket is called the dental periosteum. The thin layer of dense bone lining the socket is called the lamina dura. The gum tissue surrounding the neck of the tooth is attached to the tooth and helps to support it.



*The upper and lower jaws of the human head showing the roots and crowns of the teeth: (1, 2) incisors; (3) canines; (4, 5) bicuspids; (6, 7, 8) molars*

**Human Dentition.** The complete deciduous dentition numbers twenty teeth. These include four incisors, two canines, and four molars in each jaw. The first incisors make their appearance between six and eight months of age. The second incisors erupt in the seventh to ninth month. The first molar appears next, between the fourteenth and eighteenth month; and the canines, which are situated between the second incisor and first molar, erupt in the sixteenth to eighteenth month. The second molar, which is the last tooth in the arch, erupts between the eighteenth and twenty-fifth month.

The first and second deciduous incisors and the canines in the upper and lower jaw have one root each. The upper first and second deciduous molars have three roots, and the lower molars two roots each. These roots diverge considerably to allow room for the permanent premolars to develop between them. When the deciduous teeth are to be replaced, there is a breakdown and absorption of the roots and of the supporting structures of the teeth. With the attachment destroyed, the teeth are shed.

The complete permanent dentition has thirty-two teeth. These include four incisors, two canines, four premolars (bicuspids), and six molars in each jaw. The first permanent incisors erupt at the age of six to eight years; and the second incisors between seven and nine years. The canines appear between ten and twelve years. The first premolar, which replaces the deciduous first molar, erupts during the ninth to eleventh year; while the second premolar, replacing the sec-

ond deciduous molar, erupts between the eleventh and thirteenth year. The premolars are named for their position in the mouth in front of the permanent molars. The first permanent molar appears behind the second deciduous molar in the fifth to seventh year. The permanent second molars erupt in the twelfth to fourteenth year. The third molar, or wisdom tooth, as it is commonly called, may erupt any time after the sixteenth year. Very often the mandible is not sufficiently developed to accommodate these teeth and surgical removal is indicated. Third molars may be completely absent in some individuals.

The four incisors and two canines in the upper and lower jaws are single-rooted teeth, as are the second premolar in the upper jaw and the first and second premolar in the lower jaw. The first premolar in the upper jaw usually has two roots. The first and second molars in the upper jaw have three roots—two toward the buccal (cheek) side and one toward the lingual (palate). The first and second molars in the lower jaw have two roots, one on the mesial (front) and one on the distal (back) portion of the crown. The third molars in the upper jaw present many irregularities in the roots. The roots may be fused or there may be three roots, similar to the first and second molars. The lower third molar usually has two roots that are fused together.

## DISORDERS OF THE TEETH AND THEIR TREATMENT

Teeth are subject to a variety of disorders. Faulty development may result in malocclusion. Caries produces decay of the hard structures. The pulp may become infected. Diseases of the supporting tissues affect the teeth. Missing structures must be replaced and existing defects corrected. Each type of disorder requires special treatment.

**Orthodontia.** Orthodontia is the phase of dentistry which deals with the position and relationship of the teeth in the upper and lower jaws. It attempts to establish the best possible relationship for chewing efficiency, swallowing, proper breathing habits, and physical appearance. Edward Hartley Angle, one of the pioneers in orthodontia, established the basic concept of an ideal normal occlusion, which is based on an understanding of the shapes of the various teeth and their particular place and function in the dental arch.

On the chewing surfaces of the premolar and molar teeth there are cusp and groove formations. From the top of the cusp down, an inclined plane is formed. This inclined plane also exists from the cutting edges of the incisors and the cusp of the canines. It is the relationship of these inclined planes in the lower and upper jaw to each other which contributes to the chewing efficiency of the teeth.

The prenatal causes of malocclusion include heredity, diseases (syphilis), abnormal development, failure to develop certain teeth, intra-uterine pressure, and nutritional deficiencies in the mother. After birth, nutritional deficiencies, diseases of childhood, and disturbances in the endocrine system may be responsible. Other factors causing malocclusion include losing the deciduous teeth too early, or retaining these teeth too long. Habits such as thumb sucking and lip biting may contribute to a poor occlusion.

Treatment in orthodontia includes establishing the best condition for normal growth and development and eliminating any conditions that may interfere with this process. Orthodontic appliances may be necessary. The teeth are brought into position in the upper and lower jaws for maximum efficiency and cosmetic benefit.

**Dental Caries.** Dental caries is a disease process which results in a breakdown of the hard structures of the teeth. The protective covering of enamel and the dentine underneath are attacked by acids produced in the mouth. The inorganic salts, primarily calcium phosphate, which make up the main portion of the enamel and dentine are broken down, with the resulting decalcification of the tooth. The remaining organic matrix in the enamel and dentine is dissolved by enzymes in the mouth. This process accompanies and follows the mechanism of decalcification.

There is general agreement that carbohydrates are changed into acids through bacterial activity. The bacteria involved are the acid-producing lactobacilli and streptococci. These bacteria produce enzymes which react on carbohydrates and convert them into lactic and other acids which are formed in all mouths, regardless of the presence or absence of caries. If the saliva fails to neutralize the acid, decalcification will follow. Cavities usually begin on the surface of the teeth on which bacteria can attach themselves and remain undisturbed.

Immunity to dental caries, while extremely rare, does exist in some mouths. In the United States, 2 to 5 per cent of the adult population demonstrate immunity to dental caries. Some races, such as the Eskimo, and persons living in certain areas of India, show a remarkable absence of dental caries. A change in the environment and assumption of living habits that approximate Western civilization will often produce a marked breakdown in the immunity, with subsequent decay. The presence of carbohydrates in the diet is an essential factor in the development of dental caries in most people. During World War II, when the use of sugar was restricted in Finland, Norway, Sweden, and Denmark, there was a definite decrease in caries which was apparently directly related to the sugar restriction. On the other hand, some individuals may consume large amounts of sugar and yet remain relatively caries-free. In these cases, the possible neutralizing acid factors in the saliva, the rate of salivary flow, and the relationship of the teeth in the dental arch are of importance. The acid formation from the breakdown of sugars does not have to be completely neutralized; rather the proportion must be reduced. The amount of flow of saliva exerts a considerable influence on the amount of acid that may be neutralized. The length of time that food remains in the mouth is a contributing factor to the amount of acid formed, and the position of the teeth contributes to the retention of food for longer periods. In this connection, orthodontia is an important factor in preventive technique to minimize tooth decay. Brushing the teeth immediately after eating will also help reduce dental decay.

*Treatment of Dental Caries.* In order to arrest dental caries, it is necessary to remove surgically all the decayed tooth structure. The tooth must then be prepared to receive a filling which will restore the tooth to normal function. The outline of the filling is based on a preventive approach to recurring decay. The filling materials used are gold foil, cast gold, baked porcelain, synthetic cements, plastics, and silver amalgam. The type of filling to be used is dependent on the requirements of the particular restoration.

*Fluorides.* It has been demonstrated that persons living in areas with a concentration of fluoride in the water supply show a marked resistance to dental caries. If the concentration of fluoride is too high, it may produce a disease of the teeth called fluorosis, in which the enamel takes on a mottled, brown stain. A lesser concentration of fluorides, however, will produce a beneficial effect, and many areas in the United States are adding small percentages of fluoride to their water supplies.

The fluorides are also being used in a 2 per cent solution of sodium fluoride for direct application on the surfaces of the teeth as a preventive for dental caries. Experiments have shown that this is effective only on teeth recently erupted. Clinical results have shown a definite decrease in the number of cavities after these applications. Another method includes the increased supply of fluorides through daily supplements in the diet. There was not enough evidence in 1950 to evaluate these results conclusively.

The pulp of the tooth becomes infected when it is exposed to the micro-organisms present in the mouth. Any physical injury to a tooth may also cause an infection of the pulp to develop. Once this infection has taken place, there are only two alternatives for treatment. Either the tooth must be removed or root-canal therapy must be instituted to preserve the tooth.

**Root-canal Therapy.** Root-canal therapy is a method by which the infected pulp is removed from the tooth and the root canals and pulp chamber are disinfected and filled. This is done to prevent any infection from gaining access to the surrounding structure beyond the apical foramen of the roots. With this method it is possible to retain the usefulness of the tooth in the mouth, without causing harm to the body generally. The materials used for the filling of root canals include the dental cements, metals, and gutta-percha.

**Periodontia.** Periodontia is the study of the supporting structures of the teeth. Diseases involving the attachment of the teeth are probably as old as man. Destruction of the alveolar bone around the roots of the teeth and the presence of calculus deposits on the roots have been discerned on skulls of the earliest cave dwellers.

Some of the signs of periodontal disease include changes in the color, form, and texture of the gum tissue surrounding the teeth. X ray may reveal changes in the bone structure around the roots. An exudate may appear from the gum margin at the neck of the tooth, and the teeth may exhibit an abnormal looseness.

Periodontal disease may be produced by improper occlusion, where forces resulting from chewing cause injury to the attachment apparatus of the teeth. Improper brushing, diet, habits such as nail biting and lip biting, calculus deposits on the roots of the teeth, grinding, poorly constructed fillings, endocrine disorders, and allergies may also be contributing factors. Treatment includes removing the causative factors and correcting the occlusal relationships of the teeth.

**Prosthetics.** Professionally defined, "prosthesis is the science and art of providing suitable substitutes for the coronal (crown) portions of teeth, or for one or more lost natural teeth and their associate parts, in order that impaired function, esthetic appearance, comfort and health of the patient may be restored."

While preventive dentistry has advanced considerably in recent years, the premature loss of teeth is still a major problem. Methods of tooth replacement include the fixed bridge, the removable partial denture, the full crown to restore the crown portion of the natural tooth, and the full denture to replace all the natural teeth in the arch. The fixed bridge is attached to the two teeth adjacent to the missing tooth or teeth. The abutment (attachment) teeth are prepared to receive some type of precision casting, usually in gold, which is cemented to the teeth. These attachments support the appliance restoring the missing teeth. This type of bridge cannot be readily removed by the patient or dentist. In the anterior region of the mouth, these gold abutments are usually covered with a baked porcelain crown, for cosmetic reasons. Plastic crowns are also used for this purpose. The removable partial denture is an appliance which rests on the soft tissue of the mouth. The natural teeth in the mouth may be used for retention and secondary support. This type of replacement can be easily removed by the patient. The full denture, replacing all the teeth in the dental arch, depends on some means of suction and on perfect conformity to the soft tissues of the mouth for its retention.

The type of replacement varies with the particular condition to be corrected. The materials used in the construction of prosthetic appliances include gold, acrylic resins, and steel alloy. The teeth may be made of baked porcelain, plastic, or metals. *See also* Comparative Anatomy; Dentistry; Mammals; Man, Functional Anatomy of; Mouth Diseases; Physical Growth. G. A. H.

**TEFILLIN.** *See* Tephillin.

**TEFLON.** *See* Plastics (*Commercial Plastics*).

**TEGNÉR, ESAIAS** [tɛŋne'r] (1782-1846), Swedish poet, was born in the province of Värmland, Nov. 13, 1782. When he was eleven years old his mother, the poverty-stricken widow of a clergyman, could no longer support him, and the district attorney let him serve as copy clerk in his office. Later he lived in the home of a wealthy family where his older brother was a tutor, and after three years of private study he entered the University of Lund. Even as a young student he read Latin, Greek, French, German, and English, and later he studied Old Norse. He graduated from the university in 1802, and for ten years was instructor and assistant professor in aesthetics there, receiving an appointment as professor of Greek in 1812. At that time he was already one of Sweden's well-known poets.

In his first literary efforts Tegnér was influenced by Swedish poets such as Carl Gustaf af Leopold, Johan Henrik Kellgren, Frans M. Franzén, and Bengt Linder, as well as by Ossian, Milton, and Edward Young in English literature, and especially by Schiller in German. He did not share the new Romantic School's interest in German philosophy, and his attitude was also negative toward French philosophy, which had inspired the old school; it was rather the political happenings of the time which gave him his best poetic inspiration. Russia's attack on Sweden and the conquest of Finland form the background of his poem, *Krigssång för skånska lantvärnet* (1808) ("War Song of the Militia"). His political feelings were still more strongly expressed in *Det eviga* (1810) ("The Eternal"); and in *Svea,* written in 1811, he found his forte. His contemporaries regarded *Svea* as a Swedish Marseillaise, and Tegnér became at once the great national poet of Sweden.

Having joined Götiska Förbundet, a society for the promotion of interest in Swedish antiquity and the ancient Norse ideals, Tegnér used old Norse themes for his poems. An Icelandic saga gave him material for an epic cycle, *Frithiofs saga* (1825) (English translation, *Frithiof's Saga,* 1924), often called Sweden's national epic. Some of Tegnér's poems from this period express his political ideas; in others he used historical themes, as in *Karl XII* (1818) and *Axel* (1822). The idyl *Nattvardsbarnen,* written in hexameters, was published in 1820 (English translation, 1841, by H. W. Longfellow: *The Children of the Lord's Supper*). After his appointment as bishop he devoted less time than before to poetry; he suffered from melancholia, and for a time was forced to seek care in a hospital for the insane. After his recovery he wrote another idyl in hexameter, *Kronbruden* (1841) ("The Crowned Bride"). Tegnér was not only one

of Sweden's greatest poets; he was unsurpassed as an orator and writer of letters. He died Nov. 2, 1845, at Växjö. His collected works were published in Stockholm in 1918-1925 in 10 volumes. A. Wi.

**TEGUCIGALPA** [tegu'sigɑ'lpɑ], the capital of the Central American republic of Honduras, situated on the upper courses of the Choluteca River, about 62 mi. from the Pacific seaboard city of San Lorenzo. It is attractively located on an interior plateau, 3,200 ft. above sea level and completely surrounded by heavily forested mountains. There are no land routes to or from Tegucigalpa except a highway to San Lorenzo on the south and to Potrerillos on the north. However, the city is well served by an efficient air-line system which links it with other Honduran cities and with other countries. The surrounding hills and valleys are rich in gold and silver, and the mining of these minerals is a leading occupation. Shirt making and beverage bottling are the principal industries. The city, founded in 1578, became the capital of Honduras in 1880. Pop. 1950, 72,385. S. G. I.

**TEHRAN** or **TEHERAN** [tɛrɑ'n, tɛhərɑ'n], the capital of Iran, located in the foothills of the lofty Elburz Mountains, 70 mi. south of the Caspian Sea. The 12,000-ft. range somewhat isolates the city geographically, presenting a serious water-supply problem and providing Tehran with extremely hot summers. Although mentioned by the Arab geographer Yaqut, in the twelfth century, Tehran was not well known until the eighteenth century, when it was selected as the capital city. The Iranian rulers had moved their capital often over the course of centuries, locating it variously in Tabriz, Isfahan, Kazvin, and other cities. Tehran was made the capital by Agha Mohammed Khan, founder of the Kajar Dynasty, in 1785. The choice was dictated for the most part by its central location at the northern extremity of the Iranian plateau and the proximity of the tribes from which the Kajar Dynasty had originated, as well as by the fact that it lies at the conjunction of roads and trade routes from many directions. The city is about 25 mi. from the nearest river or waterway and water is scarce. Because of the city's torrid summers, a large proportion of Tehran's residents desert the city for cooler, suburban Shimran, a series of some sixty villages on the lower slopes of the Elburz Mountains. Improved roads connect Tehran with all major cities, and the Trans-Iranian Railway, opened by the Shah on Aug. 26, 1938, connects Bandar Shah on the Caspian Sea with Bandar Shahpur on the Persian Gulf. During World War II, the railway served as a vital matériel supply route for American lend-lease equipment en route to the Soviet Union. International air lines link Tehran with the major cities of Africa, Asia, Europe, and the United States.

Produce from the surrounding region is brought to Tehran, which has a modern grain elevator of large capacity as well as sugar and cement factories in the vicinity. It is also a center for the country's large textile industry and contains mills for the ginning, spinning, and weaving of cotton and the spinning and weaving of wool. The export of woolen rugs, primarily to the United States and the United Kingdom, is a leading economic activity. Pop. 1950, 989,871. J. C. Wi.

*Marshal Joseph Stalin, President Franklin D. Roosevelt, and Prime Minister Winston Churchill relax during an intermission of the 1943 conference held at Tehran.*

EWING GALLOWAY

**TEHRAN, UNIVERSITY OF,** a coeducational university, which was established by Mirza Taghi Kham Amir Kabir in Tehran, Iran, in 1934. To form Iran's first modern university, several schools of higher learning which already existed in the nation's capital were merged. These united institutions introduced modern European educational ideas and methods, and the law of 1934, which created the university, also provided for its financial and administrative independence. In 1942 the university became independent of the government, and in 1944 the Shah gave the village of Amerabad and its buildings to the university to use as a self-contained students' club and hostel and as a university center. Tehran University consists of six faculties, four affiliated schools, and the hospitals of Tehran. The faculties are: literature, philosophy, and pedagogy; law, economics, and political sciences; medicine, pharmacy, and dentistry; engineering; theology; and science. The schools affiliated with the university are the School of Arts, the Veterinary College, the Agricultural College, and the National Teachers College. The enrollment for all schools averages nearly 5,000. A.L.H-Q.

**TEHRAN CONFERENCE,** a wartime meeting of the top Allied leaders, held at Tehran, Iran, between Nov. 28 and Dec. 1, 1943. This conference was preceded by a meeting in Cairo, Egypt (Nov. 22-26, 1943) of President Franklin D. Roosevelt, Prime Minister Winston Churchill, and Generalissimo Chiang Kai-shek, at which plans were discussed for the vigorous pursuit of the war on Japan. The meeting was also a tacit admission of China to "Big Four" status. From Cairo, President Roosevelt and Prime Minister Churchill flew directly to Tehran, where they conferred with Marshal Joseph Stalin and allied military leaders on war strategy and international affairs. The invasion of Europe was planned and a tentative date decided upon. Immediately following the conference, Gen. Dwight Eisenhower was sent to London as Supreme Commander of the Allied forces to commence preparations for the assault on Europe. It was President Roosevelt's first meeting with Marshal Stalin and also the first discussion by the "Big Three" of the President's proposals for a United Nations organization. C. W. D.

**TEJU** [tɛyu'], any of several edible South American lizards of the genus *Tupinambis,* the largest (4 ft. over-all) representatives of the family Teiidae. Tejus are waxy black above, cross-banded, splotched, or sprinkled with yellow or white. Their bodies are flattened, rather than compressed, relatively stockier than those of iguanas, and have no spines. These aggressive lizards are truly omnivorous; they eat eggs, carrion, fruits, berries, chickens, rats, and other animals. Fast-running ground dwellers, they also dig well and climb to

the lower branches of trees. Their eggs have been found in termite nests. M. G. N.

**TELAMON** [tɛ′ləmɒn], in Greek legend, king of Salamis, son of Aeacus, and brother of Peleus. By Periboea he became father of Ajax. He took part in the Calydonian hunt, the Argonautic expedition, and the expedition of Heracles against Laomedon of Troy. Upon the capture of the city, Heracles gave Hesione to Telamon, and the son of this union was Teucer. G. E. D.

**TELAUTOGRAPH SYSTEMS.** *See* TELEGRAPHY (*Teletype Systems*).

**TEL AVIV** [tɛ′l əvi′v], officially Tel Aviv-Jaffa, the largest city of the state of Israel, located on the coast of the Mediterranean Sea, about 50 mi. southwest of Haifa and 35 mi. northwest of Jerusalem. It is on the low Plain of Sharon, irrigated only by two small rivers, of which only one, the Yarkom, supplies water during the arid summer season. However, despite this geographical difficulty and the handicap of a poor harbor, necessitating a lighterage to unload ships of large size, Tel Aviv has had a mushroom growth since its founding in 1909, and is now a modern city, the center of Israel's cultural and economic activity.

Tel Aviv was founded as a suburb of nearby Jaffa, and is in sharp contrast to the congested, oriental character of the older city, which has flourished since the fifteenth century, B.C. The rapid expansion and growth of the "suburb" soon covered the distance between the two cities. In 1921 Tel Aviv became a municipality dependent upon Jaffa; in 1934 it was made an independent municipality; and in 1950 the two cities were amalgamated by the Israel government. Although near the area of heavy fighting in the Israeli-Arab War, the city was not seriously damaged.

The surrounding countryside has been developed for agricultural purposes with the aid of modern irrigation methods, and wheat, vegetables, citrus fruits, olives, and melons are grown in abundance. Some sheep and goats are raised and fishing is a local industry. In addition, the plentiful supply of limestone and cement has helped immeasurably in the building of the city. Tel Aviv is also the center of the country's financial activities, and since the opening of the port in 1936 its shipping industry has become important. The commerce and industry are centered in the southern part of Tel Aviv, while the northern part has become a fine modern residential area. The city is also the seat of various national organizations and institutions, such as the Histadrut (trade unions), the Opera, the Israel Philharmonic Orchestra, and theaters. Pop. 1951, 340,000. D. H. K.-A.

**TELEGRAPHIC CODE.** *See* CODE; TELEGRAPHY.

**TELEGRAPH PLANT,** or semaphore plant, an East Indian perennial tick trefoil, *Desmodium gyrans,* belonging to the pea family. It is sometimes grown as a curiosity because of the movements of the small lateral leaflets of the trifoliate leaves. In daylight, when the air is moist and warmer than 72° F., the leaflets jerk up and down every few minutes like the arms of a semaphore. At night, the leaves droop down as if asleep. This plant grows about 4 ft. tall. *See also* SENSITIVE PLANT. E. R. C.

**TELEGRAPHY** [təlɛ′grəfi], a system of communication between two or more points in which electric impulses are transmitted and received as signals in accordance with a code. The term "telegraphy" means "far-off writing." Originally, the term was applied to semaphores and other visible manually operated systems, but in modern usage it applies only to a system employing electrical apparatus.

### WIRE SYSTEMS

In 1838 Samuel F. B. Morse demonstrated a model of his telegraph before the Franklin Institute, and, in 1844, upon receiving an appropriation from Congress, he built a line between Baltimore and Washington. It consisted of a key (switch) and electromagnet (sounder) at each end, in series with a wire and a battery; the earth acted as the return line. Either key sent a series of impulses, in the form of a prearranged code representing the various letters of the alphabet, to energize the sounder at the other end of the wire. A number of telegraph companies were founded thereafter, some licensed under Morse's patents and others employing a printing type of telegraph. These were all ultimately merged into the Western Union Company. In the meantime, cables were laid across the Atlantic by Cyrus W. Field, and others, the first permanent one being laid in 1866.

Since that time there have been evolved two-way (duplex) and four-way (quadruplex) transmission on a single line, multiplex, Varioplex, carrier telegraphy, Desk-fax, and microwave radio relay links. Indeed, telegraphy has advanced more rapidly in recent years than when first developed.

**Telegraph Codes.** In the Morse code used on manually operated lines in the United States, and the Continental code, used by foreign countries and universally in radio telegraphy, a short pulse is known as a dot, and a pulse three times as long is known as a dash. These, in combination with the intervening spaces, form the codes illustrated.

Quotation Marks

In the Morse cable code, dots and dashes are of equal length but of opposite polarity, in order to secure a better transient response with a minimum of voltage stress of the dielectric of a long cable. For multiplex, and start-stop printing systems, a series of five equal intervals is used to represent each character; the sequence of used and unused intervals determines the letter.

**Instruments.** The two basic instruments of the Morse system are the sending key and the sounder (Fig. 1). The auxiliary switch maintains a closed circuit by shunting the key contacts when the other end of the wire is sending, and must be opened when transmitting. The sounder magnet,

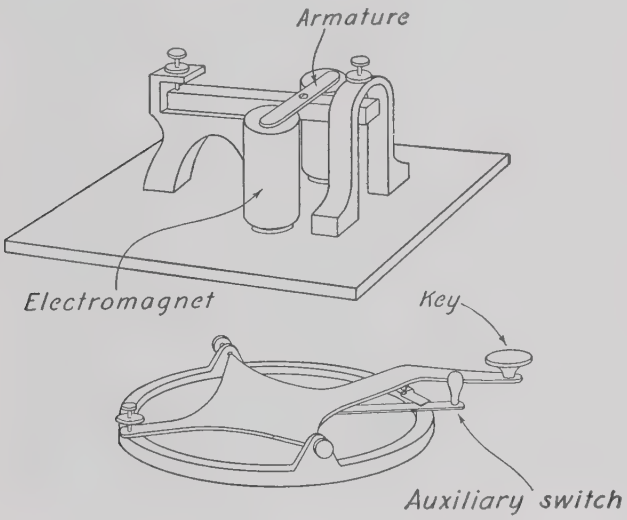

*Fig. 1—Basic instruments of the Morse system: sounder (above) and sending key (below)*

when energized, attracts the armature, which clicks when pulled down and when released. A relay is a sensitive sounder with auxiliary contacts in series with the next portion of the line and a battery. When actuated by incoming pulses, the relay sends similar stronger pulses down the next line. It has been supplanted by repeater amplifiers and is now used only in a printer mechanism.

A multiplex distributor is a rotating switch or commutator that successively switches different telegraph transmitters into a common line. A similar synchronously rotating switch at the receiving end reswitches the incoming pulses to the different printers corresponding to the transmitters. The various transmitters are thus sampled momentarily for their dots and dashes, similar to pulse modulation, and the line can handle a number of messages, while the terminal equipment operates at normal speed. The pulses are lengthened at the receiving end to their normal dot or dash duration. The transmitters send the pulses direct or via perforated tape punched out on a special typewriter. The receivers are essentially typewriters without keyboards, although in the start-stop system the machine can function as a transmitter or receiver.

The Varioplex mechanism switches a large number of intermittent services or subgroups into a multiplex system. The operating speed varies inversely as the number of services added, but owing to the diversity factor, the system is seldom slowed down to a relatively low speed. Thus, the lines are operated at a high load factor, yet each customer has a private channel available at all times.

Another recent development is the customer-switching system of Western Union. A coded set of perforations precedes each message on the tape and serves to route the message automatically from the transmitting end to the main station nearest its destination. From here, it is sent to its final destination (branch office) by push-button selection. Reperforating machines enable the rerouting to be made by an operator pushing the proper button on a switchboard to select the proper outgoing circuit.

Desk-fax is a facsimile system employing a scanning light in the transmitter, located on the premises of large custom-

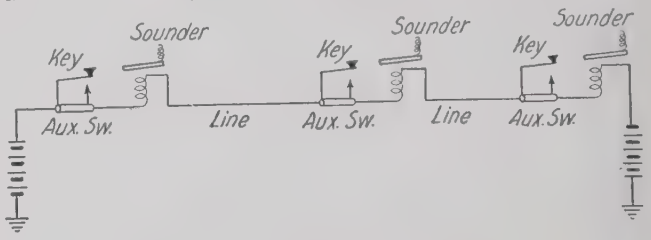

*Fig. 2—MORSE SIMPLEX SYSTEM*

ers, and a reproducing machine at the central station. The sender places his message around the transmitting drum and pushes a button. This signals the central station operator, who plugs in his receiver, and transmission starts. A special impregnated paper (Teledeltos) turns black when current passes through it, thus reproducing the original message; this can then be scanned for retransmission. The operator signals the recipient, who places a Teledeltos blank in his machine and presses a button to start his recorder; the original message is thus delivered electrically to him.

**D.-C. Telegraph Systems.** There are a large number of d.-c. telegraph circuits and systems, of which the simplex and the duplex are the two basic types. In the simplex system (Fig. 2) all components are in series; to send, the auxiliary switch is opened and the key manipulated.

In the duplex system messages can be sent simultaneously

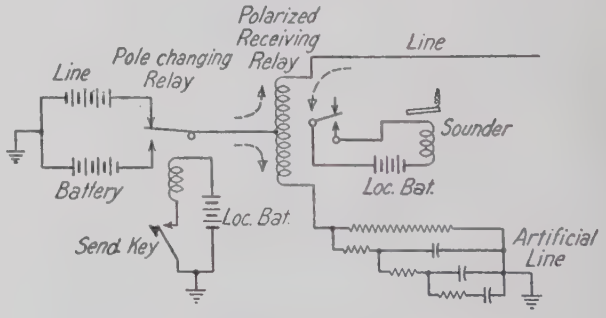

*Fig. 3—DIFFERENTIAL POLAR DUPLEX SYSTEM*

in both directions. The preferred method (Fig. 3) employs current reversal and polarized relays for reliability. The outgoing current divides equally and oppositely between the two halves of the polarized receiving relay, for equal impedances of the artificial and actual lines, and the relay does not operate; but incoming currents flow through its two half windings in series, causing it to actuate the sounder.

**A.-C. Telegraph Systems.** The a.-c. telegraph system employs carrier frequencies, each modulated (turned on and off) by the code. Two-wire lines are required, but a much greater number of services can be handled. A total band width of 36 kc. is subdivided into four carriers (Fig. 4), with each divided into two "voice" bands approximately 3600 c.p.s. wide. A voice band can accommodate a telephone conversation, or a Desk-fax message, or four high-speed busi-

ness machine services, or nine four-channel multiplex or Varioplex channels, or sixteen teleprinter channels.

Frequency modulation is used for superior signal-to-noise characteristics. A frequency deviation in one direction represents a dot; a deviation in the opposite direction represents a dash. Teleprinter channels employ a deviation of ±35 c.p.s., whereas multiplex and Varioplex channels are deviated ±70 c.p.s. Filters are employed to separate the various channels, and limiters serve to improve the signal-to-noise ratio. A discriminator then demodulates the carrier signal in a manner similar to that of a frequency modulation receiver.

## TELEGRAPH CABLES

**Local Cables. Mechanical Features.** Cables are lead-sheathed and use No. 16 American wire gauge (0.058 in.), or larger, for trunks, with paper insulation designed to withstand a 1,200-volt breakdown test. The wires are paired and usually quadded. Local cables for cities and towns employ No. 19 A.W.G. (0.042 in.) and are insulated for 500 volts. Special precautionary devices, such as pilot wires and electronic means, are used to minimize inductive interference from power lines. Cables are run aerially wherever possible, though in congested areas they are run in underground conduits. They are generally routed along a railroad right of way as, historically, railroads were the largest telegraph users.

*Fig. 5—NONLOADED CABLE CONSTRUCTION*

**Submarine Cables.** The submarine nonloaded cable, shown in Fig. 5, has a single copper conductor, usually stranded for flexibility. The principal insulation is a thick core of gutta-percha. This is protected against mechanical injury by jute yarn and a steel-armor wire sheathing, as shown. For shallow water, the cables have additional armor and jute protection against abrasion from wave action and anchors. For ocean cables, an additional wire is included out into the deep sea to act as an extension of ground for the terminal equipment. This wire obviates the use of a land ground for the equipment, with the attendant disturbances.

**Loaded Cables.** The ordinary cable, especially if as long as 3,500 mi., has excessive capacitance and insufficient inductance. As a result, very high attenuation and phase distortion exist. In order to obviate this inherent disadvantage, signals of opposite polarity but equal duration have been employed for the dots and dashes; and in order to prevent insulation breakdown, low voltages have been employed. This system necessitated the use of very sensitive syphon recorders, which printed the message on paper tape.

In 1924 Western Union introduced the uniformly loaded cable. This employed a wafer-thin permalloy metal tape wrapped around the single copper conductor. Permalloy, in contrast to ordinary iron, has a very high permeability for low magnetomotive forces and, hence, can add appreciable inductance to a conductor even when weak telegraph currents flow through it. The increase in inductance compensates for the high capacitance, and permits a modern cable to transmit a total number of words equal to that of seven nonloaded cables. By means of multichannel operation, eight individual messages are transmitted simultaneously at a rate of 2,800 letters per minute.

## RADIOTELEGRAPHY

**Systems of Transmission.** Both long and short waves are used for transmission of radiotelegraphy. Long waves are reliable both day and night; they traverse the space between the earth and ionosphere for any distance, but require large amounts of power. Short waves are efficiently reflected from the ionosphere to distant points of the earth (skip distance) and require much less power. However, owing to variation of the layers of the ionosphere, especially after sundown, different frequencies are required for day and night operation, and transmission is not as reliable as by long waves. The carrier may simply be keyed on or off (continuous wave telegraphy), or the carrier may be modulated with an audio tone or continuous wave (interrupted continuous wave). A more recent development is carrier shift: the carrier frequency is shifted by a suitable amount from its normal value to represent dots and dashes. This system gives a higher signal-to-noise ratio and is becoming increasingly popular.

**Signaling Speeds.** High signaling speeds are possible because of the relatively large band width possible with a radio carrier. Transmission from a central office is by autoheads, which transmit the five-element signals punched on a paper tape. Such signals are readily multiplexed to afford speeds as high as 200 words per minute, even though the operators, or printers (if used), receive the individual messages at only 60 words per minute.

In 1945, Western Union inaugurated an ultra-high-frequency (u.h.f.) radio link, operating at 4,000 megacycles, and higher, and transmitting a number of messages at high speed. This link consists of transmitter-receiver stations separated by as much as 55 miles. Klystron tubes are used as generators of the u.h.f. power, and radiation is from a wave guide and parabolic reflector, having a gain of 28 decibels (db.) over a dipole. Double-frequency modulation is employed: a 1-mc. subcarrier is frequency-modulated with as many as 32 voice bands, and the resulting 150-kc. band frequency-modulates the radiated carrier. In this way, the distortion for several repeaters is kept down to a satisfactorily low level.

**Radio Interference.** Atmospheric static is a major source

of interference for long waves; of fading, for short waves. The use of an audio tone enables an experienced operator to receive signals even weaker than static, and diversity reception minimizes fading. It has been found that a short wave will fade at different times at two different locations, hence, several receiving antennas and sets actuated by a common automatic volume control (a.v.c.), and connected to a common output, reduce this difficulty. Transmission on two slightly different frequencies to a common receiver (diversity-frequency reception) also reduces fading. Also, adequate frequency separation and elimination of key "clicks" (transients) help to eliminate interference.

### TELETYPE SYSTEMS

**Start-stop Printing System.** A teletype printer is a device for printing messages at a point remote from the transmitting machine. In the start-stop printing system, seven pulses are used per character: a "start" signal, five intervals for the character (see Telegraph Codes, above) and a "stop" signal. Special typewriters are employed; these have a three-row keyboard (Fig. 6), and print only capital letters, punctuation marks, and numerals. Each has a continuously revolving slipping clutch; all clutches operate at approximately the same speed.

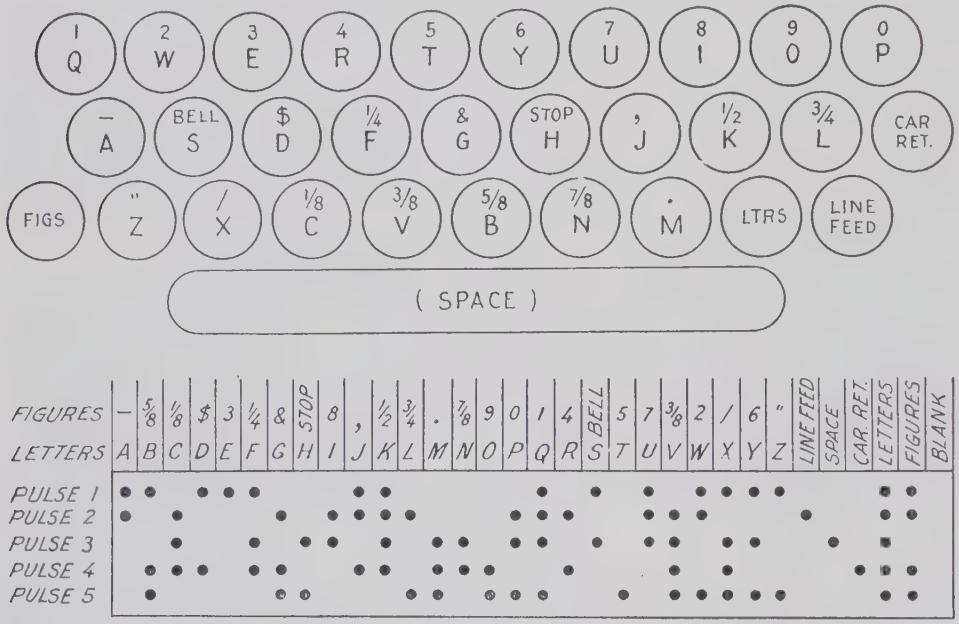

*Fig. 6—TWX KEYBOARD AND FIVE-UNIT TWX CODE*

The start pulse on each machine unlatches a movable contact arm on a rotary switch having seven segments. All contact arms are then rotated at the same speed through one revolution by the slipping clutches, when the stop pulse of the transmitting machine latches the switches at the receiving machines. Thus, the two synchronizing pulses, start and stop, obviate the need for ultraprecise speed control of the driving motor at each machine. Each type key at the transmitter, when struck, sends out dots and spaces in the five-interval period between the start and stop; the appropriate keys at the receiving teletypewriters respond accordingly. Tape and page machines can be employed simultaneously; additional signals shift the carriage or keys (depending upon the machine), and raise or lower the carriage.

**Intercommunicating Teletype Systems.** Any machine can be used as a transmitter or receiver. The typing speed is 65 words per minute, and carbon copies are possible. Connections are made as in ordinary telegraphy or telephony through switchboards, and multiplex and Varioplex operation can be employed. Regenerative repeaters that reshape the received distorted signal permit operation over any distance, and normal line distortions as high as 40 per cent in the timing of the received signal do not require synchronization of the motor speeds better than $\pm$ 75 per cent, owing to the use of start and stop pulses.

**Telautograph Systems.** The telautograph, invented by Elisha Gray, permits transmission of handwriting, sketches, and the like. It is used in electric generating stations, railroad terminals, factories, and anywhere else a written record of the message is desired. As illustrated in Fig. 7, the sending stylus is connected by arms to two rheostats. Any motion of the stylus on the platen causes corresponding variations in the setting of the two rheostat arms. Connecting wires transmit the current variations produced to a pair of bucket coils, each set in a magnet structure somewhat like a dynamic loud-speaker coil. These bucket coils are connected to a receiving stylus by a linkage similar to that at the transmitter. As the buckets move up and down, they cause the receiving stylus to follow the transmitting stylus and thus trace on a roll of paper the message sent. A receiving unit at the transmitter end enables the operator to see the message he is sending. It will be observed that two wires and a ground return

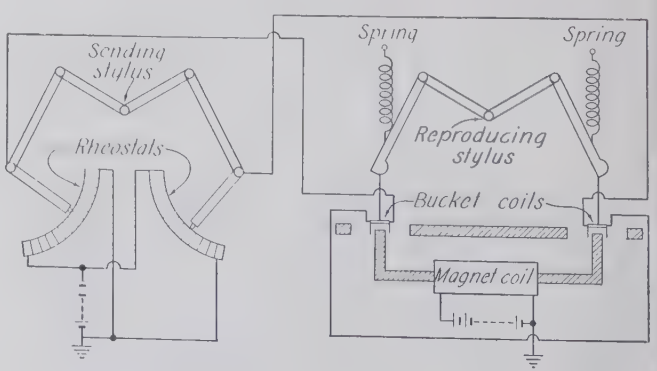

*Fig. 7—Simplified schematic diagram of a telautograph system*

are required. By the use of superimposed alternating current, the additional motions of shifting the paper and lifting the pen off the paper, as well as signaling, are obtained. *See also* FACSIMILE. A. Pr.

**TEL EL-AMARNA.** *See* TELL EL-AMARNA.

**TELEMACHUS** [təlɛ′məkəs], in Greek legend, the son of Odysseus and Penelope. He was an infant when his father went to Troy, and, when almost twenty years had elapsed, Telemachus went to Pylos and Sparta to enquire about him; on his return to Ithaca he found Odysseus already at home, but disguised as a beggar, and Telemachus assisted him in slaying Penelope's suitors. In a post-Homeric legend, Telemachus later became the husband of Circe, or of Cassiphone, Circe's daughter. *See also* ODYSSEUS; ODYSSEY, THE. G. E. D.

**TELEMANN, GEORG PHILIPP** [te′ləmɑn] (1681-1767), German composer, was born on Mar. 14, 1681, in Magdeburg. Appointed music director of the largest church in Hamburg in 1721, he became a prominent representative of the Hamburg school of composers. Although he was an extremely prolific composer, he contributed little to the advancement of the music of his time. He composed at least forty operas, forty-four Passions, thirty-two installation services, twenty ordination services, and numerous oratorios, as well as some six hundred overtures in the French style and a mass of vocal and instrumental music of all kinds. He died in Hamburg, June 25, 1767. D. L. E.

**TELEMETERING.** *See* MEASUREMENTS, ELECTRICAL.
**TELENGUT.** *See* ASIATIC TRIBES (*Turkic*).

**TELEOLOGY** [ti′liɒ′loji], from the Greek word τέλος, meaning end or goal, is the doctrine that the world as a whole or certain events in the world fulfill some end or purpose. Aristotle's philosophy is teleological because he believed that things aim at the realization of their proper nature or essence. The potentialities of matter develop into the actual things of this world because they are motivated by the perfection that would be achieved thereby. Consequently, among the causes that explain the development of a thing must be included its "final cause," the end for the sake of which it exists, or the value which is its reason for being.

A teleological explanation differs from a mechanical one in that the latter accounts for what happens by immediately preceding conditions: e.g., a baseball moves the way it does because it has just been struck by a bat; whereas a teleological explanation accounts for what happens by referring to a goal yet to be achieved—e.g., the motion of the ball could be explained as the result of the batter's aim.

It is a debated issue whether teleological concepts such as purpose are needed in the biological sciences. The fact that living things possess organs adapted to the environment and able to function so as to serve the ends of the whole organism does not necessarily prove that the ends were the cause, either conscious or unconscious, of the development of those organs.

Insofar as conscious intent or design is involved, teleology becomes synonymous with purposiveness. It is on this ground that some thinkers maintain that teleological explanations are relevant and legitimate only for the behavior of human beings and perhaps some of the higher animals that are capable of conscious purposes. Galileo was rejecting teleology when he argued that the way to find out whether there are satellites revolving about the planet Jupiter is to look through a telescope, not, as some learned scholars maintained, to discuss whether such satellites would serve any purpose.

In ethics a theory is said to be teleological when the moral rules of conduct it enjoins are justified by the value of the ends to which the conduct leads or is intended to lead. Such a theory is distinguished from one in which the moral worth of conduct is not determined by the value of the ends.

In religion one of the best known arguments for the existence of God is a teleological argument. A purely mechanistic account of the world is said to be inadequate to explain the order in nature and the adaptation of part to part. From this it is concluded that the world must be the product of a designing Providence or God. The English theologian William Paley (1743-1805) argued that, just as a watch whose parts fit nicely together presupposes a watchmaker who aimed at producing a mechanism to keep time, so an orderly world presupposes a divine Author who created the world because he saw that it would be good. The purposiveness that nature seems to exhibit is not, then, to be sought in nature itself by scientific methods; it is to be attributed to a transcendent Being.

The philosopher Kant maintained that neither the apparent design of the world as a whole, nor of organisms within the world, can be explained mechanically from knowledge of the constituent elements. Nevertheless, he rejected the teleological argument for God and argued that, whatever may be the limitations of a mechanical explanation for living things, the concept of purpose cannot be legitimately applied in natural science. A. G. R.

**TELEPATHY.** *See* PSYCHICAL RESEARCH OR PARAPSYCHOLOGY.

**TELEPHONY** [təlɛ′foni], an electrical system for transmitting sound. A transmitter transduces the sound into electrical currents; these are transmitted by conductors to a receiver, which reconverts the currents into sound, once more. The telephone is a telegraph system in which a transmitter (microphone) and receiver replace, respectively, the telegraph key and sounder.

### THE TELEPHONE

In 1876, Alexander Graham Bell received a patent for a practical electrical telephone. As shown in Fig. 1, sound waves vibrate the transmitter diaphragm, thereby varying the air gap and magnetic flux. The latter induces a corresponding voltage in the two coils, causing a current to flow

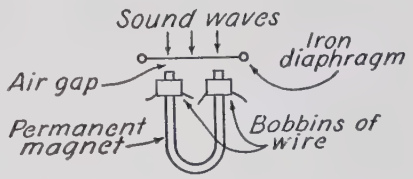

*Fig. 1 — Principle of operation of first practical telephone*

through them and then through the bobbins of a similar receiver unit connected to the transmitter by a pair of wires. The varying current produces flux variations in the receiver, and causes its diaphragm to vibrate and set the adjacent air in motion, thus reproducing the sound waves.

In 1878 David Edward Hughes, among others, invented a microphone type of transmitter, which produced more electrical energy from a local battery than the impinging sound energy; Fig. 2 shows a more modern form. The vibrating diaphragm varies the electrical resistance between the carbon contacts, producing a much larger varying current than the

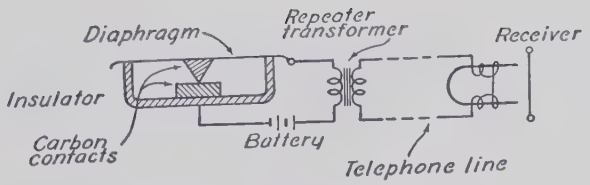

*Fig. 2—Principle of operation of a more modern form of telephone*

original Bell transmitter. This microphone, although irreversible, is a kind of amplifier and actuates the receiver very strongly. Modern units employ carbon granules as a plurality of microphone contacts actuated by the diaphragm to give still greater output; and this, in conjunction with series inductances (loading coils) to decrease the high-frequency losses, and the use of vacuum-tube (repeater) amplifiers, has served to extend transmission clear across the continent.

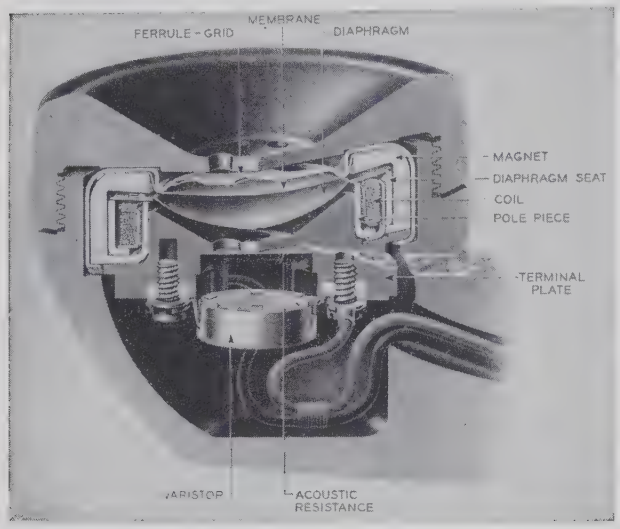

*Fig. 3(a)—Sectional view of the ring armature receiver in a handset*

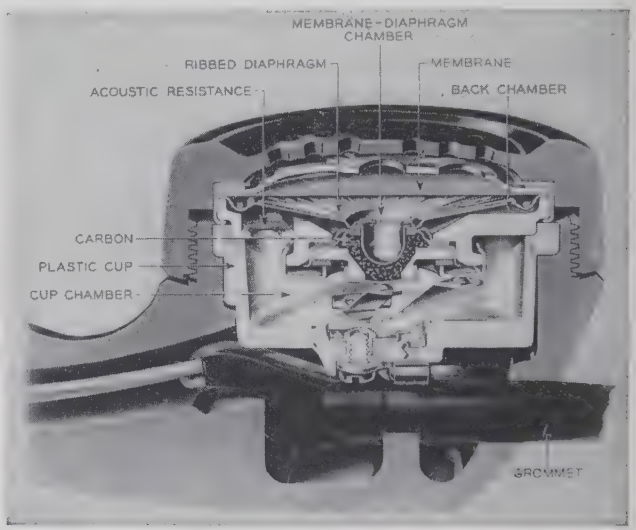

COURTESY OF BELL TELEPHONE LABORATORIES

*Fig. 3(b)—Sectional view of the transmitter in a handset*

**Telephone Transmitters and Receivers.** A modern handset contains the receiver (Fig. 3*a*) and transmitter (Fig. 3*b*) in one housing. The transmitter diaphragm is clamped rigidly at its periphery to enhance the high-frequency response, and is coupled to a doubly resonant system consisting of a cavity and chamber to broaden the response. The carbon chamber contains the carbon granules the contact resistance of which is varied by the vibration of a diaphragm. The receiver consists of an annular magnet system enclosing a coil, and an iron ring armature caused to vibrate in the air gap by the current in the coil. An attached phenolic-impregnated fabric diaphragm, in the shape of a dome, vibrates and sets the air in motion in the canal of the ear. Both units are about 5 decibels more efficient than the handset they supersede.

**Substation Circuits.** A common battery in the central office energizes the handsets in the various substations. Fig. 4 shows a common-battery anti-sidetone dial-type set, or substation. When the handset is picked up, one of the switch contacts disconnects the ringer and connects line $L_2$ to the handset, while the other switch contact connects $L_1$. The third switch contact opens and unshorts the receiver. When the dial is actuated, contact $A$ momentarily shorts the receiver, while contact $B$ pulses the line in accordance with the number dialed. The filament heats up in inverse manner to the length of the connected loop or line, and the thermistor's resistance varies inversely as the filament's temperature to which it is thermally coupled. It thus shunts the receiver less on a longer loop, allowing the receiver sensitivity to increase to compensate for the longer loop. The varistors act as protective shunts. The anti-sidetone circuit consists of the induction coil having primary, secondary, and tertiary windings, as well as a balancing impedance to maintain the action over a wider frequency range. This circuit minimizes the audio currents in the receiver from its own transmitter, thereby permitting the subscriber (telephone user) to speak louder. It also prevents the room noise picked up by the transmitter from masking the incoming signal in the receiver.

**System Layout.** The subscribers' substations, in general, are connected by individual pairs of wires to a control station, or exchange. Here, connections between associated substations, or between two substations of different exchanges, can be made either manually or automatically (dial system); the latter system predominates today. The dial system employs either the step-by-step mechanism, for small exchanges; the panel system, for the larger exchanges; or the

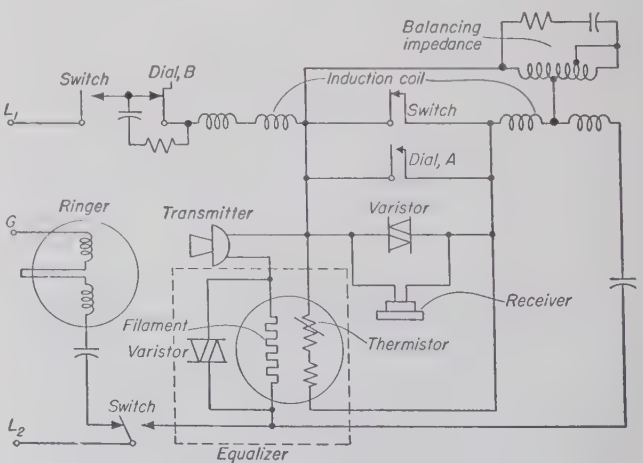

*Fig. 4—Common-battery anti-sidetone dial-type set, or substation*

crossbar system, more recently developed as an improvement over the panel system.

The subscribers to an exchange, and the lines in it, are divided into groups. In the step-by-step system, an idle "line-finder" switch locates the caller's line in his group, connects it to a selector, and is then disconnected to handle other incoming calls. The selector gives the subscriber the dial tone, and he starts dialing. The dial impulses actuate the selector to choose a certain group of lines in the exchange, and then an idle one from these. Further dial impulses from the succeeding numbers dialed cause other selectors to choose an idle line in another subgroup, or idle trunk to another exchange, as required. This action proceeds, step-by-step, until the last two numbers cause a final selector (a multibank switch called a connector) to choose the proper bank or level in which the called subscriber is connected in common with others in his group, and then to rotate the connector across the contacts of this switch bank to those of the desired subscriber. If he is free, the call is completed; if his line is busy, connections are made to the busy signal, instead.

In the panel and crossbar systems, the numbers are stored in a "sender" group of relays. The sender actuates other switches, which send revertive pulses back to the sender and stop on contacts when their pulses equal those dialed to the sender. Connections are thus controlled by the dialing subscriber, but are made independently of his speed of dialing.

*Nationwide Automatic Switching.* The nationwide system of automatic switching calls for a system of switching points: a National Center (NC), at St. Louis; nine Regional Centers (RC), including Canada; Sectional-Centers (SC), that handle a section of a region; Primary and Tandem Outlets (PO) and (TO), that handle parts of a section; and Toll Centers (TC), that serve a cluster of nearby tributary points in a PO or TO.

In dialing a long distance call, as many as eight intertoll trunks may be involved in tandem, all connected at switching points. Normally, a minimum number of "high-usage" trunks, which avoid intermediate switching points, are used: but if these are all busy, "final" trunks between switching centers are automatically substituted.

Although operator toll dialing is intended at the start, ultimately, direct customer dialing is contemplated. A typical number will be 601-CA3, 4567, of which the first three numbers will indicate the area of the country; the next two letters and number, the office; and the remaining four, the substation (subscriber). For calls in the same area, the first three letters will be omitted. To handle this operation, a very complicated switching system incorporating punched metal cards, an optical system, and phototransistors, have been developed as a part of a so-called translator, used in conjunction with crossbar switches, senders, markers, and decoders.

**Carrier Telephony.** In order to transmit several messages on one pair of wires, a method similar to radio broadcasting is employed: each message is used to modulate a different high-frequency wave, known as a carrier. At the receiving end, special band-pass filters sort out the different carriers, demodulate them, and impress them upon the corresponding receivers. Suppose a 100-cycle speech component amplitude-modulates a 30,000-cycle carrier. The result is three frequencies: 30,000 c.p.s.; $30{,}000 - 100 = 29{,}900$ c.p.s.; and $30{,}000 + 100 = 30{,}100$ c.p.s. The last two are the lower and upper sidebands, respectively. It is possible to suppress either of these and still retain the 100-cycle intelligence; even the carrier can be suppressed and reinserted locally at the receiving end. Suppressing one set of sidebands is called single-sideband transmission, and halves the bandwidth required.

Carrier transmission is superior to that of the audio frequencies, alone, and permits a large number of channels on a given pair of wires or other service. For example, the N-carrier system, used on cables for short distances (15 to 200 mi.), has twelve channels. Type O carrier is used on open wire lines, and Type L carrier on coaxial cables; a pair of coaxial cables accommodates 600 channels (two-way transmission). Moreover, one repeater amplifier at each point in the line can amplify the entire group of modulated carriers, instead of merely one audio band. Although the terminal equipment is complicated and expensive, carrier telephony is employed even for short distances, as well as for long distances.

**Interference, Cross Talk.** All communication systems suffer from interfering signals originating in other equipment or in other channels. Telephone lines are often strung parallel to the right of way of power lines, if not on the same towers, and pick up energy from the power line either through inductive or capacitive coupling. Also, one pair of telephone wires may induce currents in another, or different modulated carriers may insert some of their intelligence on one another via nonlinear circuit elements (cross modulation). The last two types of interference are known as cross talk. Other sources of interference are the random thermal-noise voltages in resistors and shot-effect noise of the vacuum tubes used in the repeater amplifiers, as well as carbon hiss from the granules in the transmitter.

Power-line and cross-talk interference can be minimized by using metallic conductors for both sides of the circuit, instead of ground return, so that the impedances from each side of the line to ground are equal (balanced-to-ground). Also, reversing the conductors periodically and interchanging the positions of the lines on the pole lines or cables (transposition) helps to balance out the interfering signals. In addition, the energy level of the signal must not exceed certain practical values, such as 20 decibels (0.06 watt), in order to keep the cross talk down to a manageable level.

## TELEPHONE LINES

**Subscribers' Lines.** Paper is the usual insulation used for the copper-wire lines; in the Bell System, it is in the form of paper pulp over each conductor. A line may consist of two wires twisted together for the purpose of transposition to reduce pickup of extraneous signals; or two twisted pairs may be twisted together to form a quad, in order to furnish two metallic side circuits plus one phantom circuit. Groups of 100 pairs, or multiples thereof, form a cable; the group can be a mixture of pairs and quads of various sizes. A cable can have as many as 21 groups (2,100 pairs).

**Toll Lines and Cables; Mechanical Features.** Telephone lines may be in the form of tinned copper rubber-covered overhead wires (No. 22, 19, or 16 American wire gauge—0.0253, 0.0359, or 0.0508 in. diameter) mounted on insulators on the crossarms of poles (open-wire lines); of aerial cables, maintained under nitrogen gas pressure to check for leaks and warn of entry of moisture; and of underground cables buried directly in the ground (armored cable) or else run in ducts.

Lead, hardened by alloying with small amounts of antimony (about 1 per cent) or tin, is usually used for the cable sheath to exclude moisture; more recently, polyethylene has been successfully used. In submarine cables for crossing rivers and other bodies of water, treated paper, rub-

ber, or gutta-percha is used for insulation; and a continuous spiral of high-permeability metal (permalloy) is used over each pair of wires in the cable as inductive loading, if the cable is very long.

**Telephone Repeaters.** Telephone repeaters are amplifiers inserted along a telephone line at suitable intervals (from 50 mi., for open-wire lines, down to 8 mi., or so, for cables) to compensate for the attenuation of the signal in the section of the line preceding the repeater. Since an amplifier transmits in one direction only, separate channels are required, unless a balancing network is employed.

**Coaxial Lines.** To minimize interference pickup, a coaxial cable can be employed instead of a two-wire line, balanced-to-ground. A coaxial cable has an outer tubular conductor concentrically surrounding an inner conductor and separated from it by insulating ceramic or polyethylene disks. Dry nitrogen gas is usually pumped into it to exclude moisture and to prevent corrosion. The losses decrease as the size of the cable is increased. The standard size is ⅜ in. for the inner diameter of the outer conductor. Owing to skin effects, the currents are more and more confined to the inside of the outer conductor and the outside of the inner conductor, as the frequency is increased. This condition makes the cable particularly well shielded at the higher frequencies where inductive and capacitive pickup is normally greater, and, hence, results in a more favorable signal-to-noise ratio. The coaxial cable can be operated over wide frequency bands, and, therefore, is particularly suited to carrier telephony and television.

## RADIOTELEPHONY

**System of Transmission.** Various frequencies and methods of modulation are employed in radiotelephony, depending upon the distance of transmission, the importance of the link, and the privacy required. Low (long-wave) frequencies —40 to 100 kilocycles (kc.)—were used originally, but are now merely for standby purposes. Higher (short-wave) frequencies—5 to 30 megacycles (mc.)—are used because they are freer from atmospherics and can traverse long distances by one or more reflections from the ionosphere, or Heaviside layer; however, they can be disrupted by magnetic storms. Different frequencies are required for day and night operation, and as many as five frequencies are required for transatlantic transmission. Short-distance point-to-point transmission uses the 100- to 5,000-kc. and 30- to 3,000-mc. bands, or even higher.

At the lower frequencies, amplitude modulation, either double sideband and carrier, or single sideband with carrier suppressed and supplied locally at the receiver, is employed. In the ultrahigh bands, from 100 mc. up, phase or frequency modulation is often used, as well as pulse-time modulation.

To ensure privacy, as in transatlantic transmissions, the speech is scrambled by inverting and/or transposing bands in the audio spectrum before modulating the carrier, and the code is changed periodically.

**Installation.** The installation of the receiver and transmitter depends upon the type of service desired.

*Long-Distance Systems.* Owing to the high transmitted power, the receiving and transmitting antennas are generally separated by an appreciable distance, and, if directional, have their nulls in line, in order to prevent the transmitter from paralyzing the receiver. Usually, different frequencies are employed for the two directions of transmission; further refinements are to shut off the transmitter carrier by voice-operated relays when the receiver is operating, and vice versa. Short-wave reception generally involves the use of rhombic antennas, which are directional and broad-band in operation.

*Ship-to-Shore Systems.* Here, the frequencies range from 2 to 30 mc. and 152 to 162 mc. The coastal calling frequencies lie in the 2- to 3-mc. band, and a ship may carry two to three crystals in order to change frequency rapidly to communicate with the desired shore station. For long-distance communications involving ships on the high seas and land lines, frequencies in the 4- to 21-mc. range are used. The 152- to 162-mc. bands are employed for private communication systems by important marine commercial companies. Even though space may be at a premium, the receiver should be located in the quietest part of the ship. This injunction should be observed particularly for the receiving antenna, which should also be as far as possible from the transmitting antenna. Shore stations are moderately directional, and the receiving antenna is located in as quiet a region as possible. The antenna sites should be as close to the water as possible in order to avoid the large attenuation of any intervening land.

*Railway Systems.* Radiotelephone systems are employed by railroads to enable the caboose and locomotive of long (80-car) freight trains to communicate with each other and with stations along the right of way. The set in the locomotive operates from a 32-volt turbogenerator; that in the caboose, from a gasoline-driven generator. The ultrahigh frequencies employed, 159.51 to 161.85 mc., permit small antennas, mounted on top of the locomotive or caboose, and afford ample clearance for bridges. The transmitter power is about 10 watts, and frequency modulation is employed (±15 kc. swing). Although static is at a minimum at these frequencies, flutter effects and noise have indicated the advisability of installing additional booster stations along the right of way. The boosters are usually fed from the main stations by carrier frequency (189 kc.) along the wayside wire circuits. Reliable communication over distances of 13 mi., or more, is possible.

*Vehicular System.* Radiotelephone communication with automobiles was introduced at the close of World War II. Each car has a small receiver and transmitter, usually located in the trunk compartment, with a push-button control on the handset to connect either unit to the common antenna mounted on the roof. Receivers are located along the highway to pick up the car signal, whereas one or a few powerful transmitters radiate power to the vehicles. A selective ringing system enables any one vehicle to be called. The mobile service bands are 25 to 50 mc., 150 to 160 mc., and 450 to 460 mc.

**TELETYPE SYSTEMS.** *See* Telegraphy.

**TELEUT.** *See* Asiatic Tribes (*Turkic*).

**TELEVISION,** the transmission and reception of visual images in motion by electrical means. Actually, it consists of converting the lights and shadows of a scene into corresponding electric signals which may be broadcast, or trans-

mitted over radio relay and coaxial cable circuits. At the receiver these signals are reconverted into a visible image which recreates the original scene.

**History.** The concept of television was first advanced in 1877 by a Frenchman, Senlecq. He proposed that an image might be transmitted electrically by focusing it on a mosaic made up of a number of selenium cells, each connected to an individual electrical circuit capable of actuating a shutter, the shutters being arranged in a mosaic similar to that of the cells. In 1884, the German Nipkow proposed a simpler system in which a single electrical circuit might be used. In the Nipkow system, the image was to be scanned, that is, analyzed point by point by viewing it through holes on the periphery of a rotating disk. Each hole would trace across the image a line adjacent to that traced by the preceding hole. A selenium cell or other photosensitive device would register the amount of light passing through the holes from instant to instant, thus creating a varying current which, after passage through the circuit, would actuate a lamp illuminating a flat surface. If this surface were viewed through the holes of a second similar disk, rotated synchronously with the first, the image would be recreated. Nipkow's scheme is the basis of modern television systems.

The principle of the electronic scanner was first enunciated in 1907, when Rosing in Russia and Campbell-Swinton in England independently proposed a method of storing an image electrically on a plate, in a manner similar to the storage of the latent image on a photographic plate. The latent electrical image was to be scanned electrically by a beam of electrons which passed over the plate in a series of parallel lines and created a changing current proportional to the changes in light and shade along each line. This proposal was reduced to practice by V. K. Zworykin in 1925, when he applied for the patent on the iconoscope, the basic element of the electronic television camera. The other essential element of the electronic system, the cathode-ray tube on which the picture is reproduced at the receiver, was first constructd by Braun in the early 1900's.

The first demonstrations of television transmission over wire lines were conducted in 1925 by John Logie Baird in England and Charles F. Jenkins in the United States, both using the Nipkow-disk system. In 1927, the Bell Telephone Laboratories transmitted images by this method over telephone wires between Washington and New York. In 1933, the Radio Corporation of America demonstrated an electronic system, using the iconoscope and cathode-ray tube, between New York and Philadelphia, using radio waves with a relay at Arney's Mount, New Jersey. In 1936, public television service, using a similar electronic system, was inaugurated in London. In the same year, RCA began a large-scale field test of this system in New York City. Public television service was begun in 1939 but was interrupted in 1940 by the Federal Communications Commission to permit a review of the standards of transmission. After this review was completed in 1941, full commercialization of the electronic system was permitted by the FCC in July of that year. Broadcasts continued during World War II at a reduced scale and were resumed at an accelerated pace in 1946. Large-scale production of receivers for the public began in 1947, when twelve stations were furnishing regular service to the public in nine cities. By November 1952, more than 100 additional stations had taken the air, and were connected in a coast-to-coast network serving 20,000,000 receivers.

**Systems of Television—Requirements.** The television image is re-created by a moving spot of light, which traces a number of parallel horizontal lines across the viewing

NATIONAL BROADCASTING COMPANY

*Televising a meeting of the United Nations at their headquarters in New York City*

screen. As the spot moves along each line, its brightness is changed, under the control of the signal broadcast by the transmitter, so that it re-creates the lights and shadows along each line. When the picture area has been covered by a series of such lines, the light spot returns to the starting point and traces out another picture, differing slightly from the preceding one. This succession of pictures, like the successive frames of a motion picture, recreates the image in motion. According to the United States standards, 30 complete pictures are traced out each second, and the total number of scanning lines from the beginning of one picture to the beginning of the next is 525. (In Great Britain, 25 pictures, each containing 405 lines, are sent each second.) Of the 525 lines, approximately 35 lines are blanked out while the spot travels from the bottom of one picture to the top of the next, leaving about 490 active lines for recreating the picture. Each of these active lines is capable of being shaded with some 450 dots (picture elements) of light and shade. Consequently each picture may contain as many as $490 \times 450$, or 220,500, picture elements. On a similar basis of computation, the number of picture elements which may be accommodated in the image projected from a single frame of 16-mm. motion picture film is about 250,000. Thus the 525-line television system and the 16-mm. home movie have comparable ability to reproduce the details of a picture.

Since the television picture, containing as many as 220,500 picture elements, is sent in 1/30 sec., it follows that picture information must be sent from transmitter to receiver at an enormously rapid rate, as high as seven or eight million picture elements per second. To accomplish this rapid transmission, a correspondingly broad space in the ether spectrum is required, roughly equal to that demanded by 600 standard sound broadcasting stations. Since such space cannot be found in the broadcast or short-wave regions of the spectrum, which are already thoroughly occupied by existing radio services, television frequency assignments are confined to the very-high frequencies (vhf), channels 2-13, operating on 54 to 216 megacycles, and ultra-high frequencies (uhf), channels 14-83, operating on 470 to 890 megacycles. For connecting television stations in intercity networks, specially designed coaxial cables or radio-relay facilities must be used.

The very short radio waves used by television stations are not propagated around the curvature of the earth, as are those used for standard and short-wave broadcasting. Consequently, the range over which television transmissions may be received is limited substantially to the horizon as viewed

from the transmitting aerial. Reliable coverage over a maximum radius of 50 to 75 mi. is possible, provided the transmitting aerial is elevated from 250 to 1,000 ft. above the surrounding terrain.

**Broadcasting Programs.** The modern television camera (iconoscope and image orthicon, described under Television Cameras, below), has all the capabilities of the motion-picture camera. The image orthicon is, in fact, more sensitive to light than the fastest photographic film, when exposed for the 1/30-sec. interval allowed for each picture. This camera can televise a recognizable picture in the light of a single candle held 6 ft. from the subject. The producer of television programs is thus freed from limitation as to subject matter, so far as illumination is concerned. The principal limitation is, rather, the available detail of the recreated picture. In common with motion pictures, the television system gives the best effect when the subject is viewed in a close-up. Telephoto lenses are often used in sporting events to bring the center of action close to the viewer.

*TYPICAL TELEVISION STUDIO SCENE*

NATIONAL BROADCASTING COMPANY

**Television Cameras.** The television camera employs the photoelectric effect to translate the optical image into an electrical signal. The image is focused by a lens onto a photosensitive surface, enclosed within an evacuated glass tube (camera tube). When light strikes such a surface, electrons (minute negatively charged particles) are freed from the plate in numbers proportional to the intensity of the illumination.

*Iconoscope.* The first widely used television camera was the iconoscope. The photoelectric surface in this device is a flat plate of mica, covered on one side with a mosaic of several million separate minute droplets of cesiated silver. The image is focused optically on this plate, called the "mosaic plate," and electrons are liberated from each droplet in proportion to the value of light or shade falling on each. Each droplet is insulated electrically, by the mica, from its neighbors. Hence as the negative electrons are liberated, the mosaic of droplets is left with a distribution of positive charge which corresponds, point by point, with the distribution of light and shade in the image. As the illumination continues for the 1/30-sec. exposure of each picture, the charge is stored; that is, full use is made of the available light.

To dissect the image, a beam of electrons is directed at the mosaic plate from a side arm in the tube. This beam is caused to trace, over the mosaic, a series of parallel horizontal lines, scanning the image along each line from left to right and line by line from top to bottom. As the electron beam encounters the charged droplets along each line, it restores the charge of each droplet to equilibrium. These successive restorations of electric charge are reflected, electrically, to an external circuit connected to the rear side of the mica mosaic plate. Hence, as the electron beam moves over the charge image, an electrical signal is generated, the strength of which is proportional at any instant to the charge on the droplet being passed over by the beam at that instant. In this manner, the television signal is caused to vary in conformity with the successive values of light and shade along each line in the image. This signal, at the receiver, controls the brightness of a spot of light which is moving in synchronism with the beam in the camera, and the image is thus re-created.

*Image Orthicon.* The image orthicon camera operates on a similar principle, with refinements which increase its optical efficiency by about ten times over the conventional iconoscope. The image orthicon offers still greater sensitivity by employing what is known as electron multiplication. In this device, the electrons from the charge image are caused to strike upon several specially prepared surfaces, being reflected from one to the next. At each surface, the impact of one electron is sufficient to cause the release of approximately four "secondary" electrons, with a corresponding increase in current at each impact. By cascading several impacts, the current may be built up to a value several thousand times its original value, with proportional increase in the sensitivity of the camera. The image orthicon is currently the most widely used camera tube.

**Television Antennas.** The transmitting and receiving antennas used in television must meet rather exacting specifications compared with those used in sound broadcasting.

*Transmitting.* The transmitting antenna must be erected on as high an eminence as possible, such as a hill, tower, or skyscraper, to push back the horizon as far as possible. An antenna located well above surrounding buildings and terrain is also advantageous in minimizing the effect of signal reflections which cause ghost images, described in the next paragraph. The transmitting antenna should radiate the major portion of its signal in the direction of populated areas. If, as is usual, these areas surround the station, the antenna must not be directional in the horizontal plane. Directivity in a vertical direction is desirable, since such directivity confines the major portion of the radiated signal to angles below the horizon, where it can be utilized, and minimizes radiation above the horizon, where it would be lost to outer space.

*Receiving.* The receiving antenna, in contrast to the transmitting aerial, should have directional pickup in the horizontal plane. This directivity permits the antenna to discriminate between several signals arriving from the transmitter via different paths. One such signal, called the direct wave, travels directly from the transmitter to the receiver in a straight line. It arrives at the receiver first and is ordinarily the strongest component received. Other signals, called reflected waves, are reflected from buildings, bridges, water towers, cliffs, and other obstructions lying between transmitter and receiver. These reflected waves travel longer distances than the direct wave in arriving at the receiver and, hence, arrive later. Although they are usually weaker than the direct wave, the reflected waves are capable of producing ghost images, that is, faint replicas of the primary image, displaced to the right on the receiving screen. A directive receiving aerial, aimed in the direction of the direct wave, is of assistance in minimizing these ghost images and also in discriminating against interference from other stations.

The simplest receiving aerial is the so-called half-wave dipole, a horizontal rod with an insulating segment at its center, mounted on a vertical support. The length of the rod should be approximately one-half of the wave length employed by the transmitting station, for example, 2 meters for a station operating at 4 meters wave length. Such an antenna has maximum sensitivity along a line at right angles to its length. Higher degrees of directivity and proportional increases in sensitivity can be achieved by assembling an array of several half-wave dipoles parallel to one another.

When it is desired to receive all of the channels assigned to television stations, a single receiving aerial is at a disadvantage, since its length is best suited for one wave length. The antenna can be made to cover several station frequencies if the rod is of large diameter, or if each half consists of several fanned-out rods. Usually, however, at least two antennas are required to cover all the station frequencies. The receiving aerial should be located as high, and as clear of obstructions, as possible.

The lead-in wire is composed of two conductors, one connected to each of the dipole segments. The lead-in should be constructed of high-quality materials to avoid loss of the signal during its conduction from the antenna proper to the receiver. Signal reflections along the lead-in must also be eliminated, since the slightly displaced images thereby introduced may impair the fine detail of the image.

**Television Receivers.** A television receiver consists of two essential units, the picture receiver and the sound receiver. The transmitter radiates two corresponding signals, one carrying picture and synchronizing information, the other the accompanying sound. Both signals are picked up together by the receiving aerial and are tuned in by the same receiving circuits.

The sound circuits are of the frequency-modulated type. The picture circuits include the picture-signal amplifier and detector, the picture tube, and the synchronizing and scanning circuits which form the scanning pattern on the picture-tube screen. The picture amplifier and detector accept the picture signal as it arrives from the transmitter and amplify it to sufficient strength to control the brightness of the scanning spot as it moves over the picture-tube screen.

*Picture Tube.* The picture tube (cathode-ray tube, kinescope) is a funnel-shaped glass structure, closed at the wide end, and highly evacuated. Inside the glass at the wide end is a coating (a mixture of fluorescent powders) which glows when electrons impinge on it. This coating is the picture screen. The opposite (narrow) end of the tube contains an electron gun, a structure which forms a beam of electrons and directs it at the screen, where it creates a spot of light. The brightness of this spot is controlled by applying the picture signal to an electrode in the electron gun.

*Deflecting System.* At the mouth of the electron gun, where the electron beam first emerges, is the deflecting system, which causes the electron beam to change its direction. The spot formed by the beam is thus caused to traverse the screen in the parallel lines of the scanning pattern. It is necessary that these lines be formed in exact synchronism with the corresponding scanning motions in the camera at the transmitter. Synchronism is achieved by so-called synchronizing signals, which are generated at the transmitter and transmitted as a part of the picture signal. The synchronizing signals are separated in the receiver from the amplified picture signal and are applied to the deflecting system. In this manner, the spot of light is constrained to move over the screen in step with the corresponding scanning motion at the transmitter, changing in brightness as it moves and recreating the image point by point. Although only one spot is illuminated at any one time, the eye retains the impression for the full duration of each picture, or $\frac{1}{30}$-sec., so that the picture area appears as though it were continuously illuminated at all points.

*Magnifying System.* The picture screen may be viewed directly, or the image may be magnified and projected through a mirror and lens system to a larger viewing screen. In the latter case, the image formed on the cathode-ray screen must be very bright, since the magnification reduces the brightness in proportion to the increase in picture area.

*Contrast and Brightness.* The contrast control affects the amplification of the picture signal. Advancing this control causes the dark areas of the picture to become darker and the light areas lighter. The brightness control adjusts the over-all brightness of the picture, increasing or decreasing the light in all parts of the picture. In general, it is necessary to adjust both contrast and brightness controls until the picture is bright enough to be viewed comfortably in the surrounding illumination, while at the same time preserving an even gradation of light from white to black. Modern picture tubes can display a contrast ratio, between maximum white and black, of 60 to 1, which compares favorably with the contrast of motion-picture images. The maximum brightness currently available is about 75 foot-lamberts, which compares with less than 5 foot-lamberts on the average motion-picture theater screen.

*Focus and Synchronization.* The focus control affects the size of the scanning spot; it is adjusted to the position giving

the best rendition of fine detail. The synchronizing controls are adjusted if the image should fall out of synchronism with the transmitter, as evidenced by a torn appearance of the image or by the fact that the image as a whole moves vertically up or down on the screen. In many receivers, the synchronizing and focus controls are automatic in operation and are accessible only from the rear of the cabinet for adjustment during installation or for servicing.

*Size of Image.* As the development of television receivers has proceeded, the size of picture tube screens used in commercial receivers has increased from 10 to 30 in. The most popular sizes in 1952 were the 17-in. and 21-in. rectangular screens; the 27-in tube was expected to be popular in 1953.

Projected images up to 3 by 4 ft. in size have been offered in home receiving equipment, but are little used because they are so dim as to require complete darkening of the room. Projection television systems for theater use were installed in more than 100 theaters by 1952; in one drive-in theater, an image measuring 18 by 24 ft. was projected during the 1952 Walcott-Charles heavyweight prize fight.

*Test Patterns.* Most television stations broadcast a test pattern prior to each broadcast to aid the viewer in adjusting his receiver. This pattern contains areas of several shades of gray as well as white and black, one or more circular figures, two or more groups (wedges) of converging lines, as well as the station call letters.

**Color Television.** Late in 1950, the Federal Communications Commission (FCC) authorized the transmission of color television images by the "field-sequential" method, according to standards advocated by the Columbia Broadcasting System (CBS). In this system, the television camera is fitted with a rotating disk containing segments of transparent colored filters in the three primary colors, red, green, and blue. The rotation of the filter disk is synchronized with the scanning of the image, so that successive images are perceived in successively different colors. Thus, the scene is scanned first in red light, then in green, next in blue, and then again in red, and so on. At the receiver, a similar rotating disk, large enough to cover the screen of the picture tube, is rotated synchronously with that at the transmitter. Thus, when the camera is viewing the scene through a red filter, the viewer perceives the screen through a corresponding red filter; the filters correspond similarly during the images scanned in green and blue light. Since the images follow one another in rapid sequence, the primary-color images fuse in the mind of the viewer and a full-color reproduction results.

To avoid flicker in this system, the images must be scanned at a much faster rate than is required in the black-and-white system (actually, more than twice as many pictures must be sent each second in the field-sequential color system as in the black-and-white system). Consequently, the color image cannot be received on existing monochrome receivers unless the receiver is extensively modified. This incompatibility of the CBS color system with existing television receivers placed the system under a heavy economic handicap. Moreover, the filter disk at the receiver cannot safely be rotated at the high speed required if its diameter exceeds about 24 in., which limits the picture size to about 12 in. For these reasons, when color broadcasts were instituted in 1951 by CBS in New York, other broadcasters did not follow suit and the public showed little interest. Production of color receivers was halted later that year by the National Production Authority to conserve critical materials. These curbs were lifted in June 1953, but color television was not resumed pending further developments.

To avoid the limitations of the CBS system, the television industry in 1950 requested the National Television System Committee (NTSC) to study the possibilities of compatible color systems (that is, those which would permit existing black-and-white receivers to reproduce the new color transmissions in monochrome without any modification of the receivers). In late 1953 a new compatible color system, developed by the industry through NTSC, was adopted by the FCC, and regular color broadcasts on a limited scale began shortly thereafter. Known as the "simultaneous system," it transmits the three primary colors at the same time. The basic signal is identical with that used in black-and-white transmissions; and the simultaneous color signals are transmitted over the same channel in such a way that they do not affect reception existing on monochrome receivers,

COURTESY OF RADIO CORPORATION OF AMERICA

OPTICAL DEMONSTRATION OF RCA TRICOLOR TELEVISION TUBE

*In the actual RCA tricolor tube, shown to the left in sectioned form, the electron beams for each of three primary colors—red, green, blue—pass through a masking screen containing 200,000 tiny holes to activate phosphor dots on the glass viewing plate. There are 600,000 dots on the glass plate arranged in groups of three—one dot in each group for each of the three primary colors. By means of the masking screen, each color is reproduced on the glass plate in succession; the interval between colors is so short, the illusion is given of a continuous full-color picture. (1) Arrangement of blue phosphor dots on viewing plate; (2) Green dots; (3) Red dots.*

but may be utilized in color receivers to produce full-color images. Concurrently, tricolor picture tubes have been developed which employ viewing screens made of some 600,000 dots of fluorescent material, 200,000 for each of the three primary colors. These tubes, used in a compatible system, can provide a color image with all the quality of the black-and-white images in respect to detail, freedom from flicker, and suitable picture size. Commercial production of picture tubes up to 21 in. in diameter was well under way during 1954. *See also* ELECTRON TUBES (*Cathode-Ray Tubes*); FACSIMILE.

D. G. F.

**TELFORD, THOMAS** (1757-1834), Scottish engineer, was born on Aug. 9, 1757, in Elkdale, Dumfriesshire. He became a stone mason in Edinburgh in 1780 and a hewer in London two years later. He was commissioned to direct the erection of several buildings in 1784, and in 1787 he was appointed surveyor of public works for Shropshire. In 1793, Telford was designated sole agent, engineer, and architect of the Ellesmere Canal to connect the rivers Mersey, Severn, and Dee. Among the spectacular engineering feats he accomplished in carrying out this project was the building of huge aqueducts to carry the canal across valleys. Telford also engineered the Caledonian Canal, permitting navigation through Scotland from the North Sea to the Atlantic Ocean. This canal, 60 mi. long and having twenty-eight locks, was under construction from 1804 to 1822 but was not a financial success. During this period, Telford also was active in building canals in England as well as on the Continent, including the Gotha Canal (1808-1810) from the Baltic to the North seas.

Telford also built roads and bridges, including 900 mi. of roads and 120 bridges in northern Scotland. His remuneration was frequently meager, but he took great pride in these improvements for his native country. The King of Sweden conferred upon him the order of knighthood. Telford was a founder of the society which became the Institute of Civil Engineers. He died in Westminster, England, on Sept. 2, 1834, and is buried in Westminster Abbey. I. B.

**TELL, WILLIAM,** legendary Swiss patriot, is popularly believed to have been born in the canton of Uri in the latter part of the thirteenth century. The central incidents of the Tell story are supposed to have occurred in 1307, when one Gessler is said to have been tyrannically abusing his office as Austrian governor of Uri. According to the accounts, William Tell, a native of the district, refused to make obeisance to Gessler's hat which had been displayed publicly as the symbol of Austrian authority. In punishment, Tell was reputedly forced to shoot an arrow through an apple resting on the head of his son. Tell is said to have performed the feat but to have been thrown into chains upon his confession that, had he harmed his son, he would have sped a second arrow through the governor's heart. The story continues to relate that while Tell was being taken across Lake Luzern as a prisoner, a violent storm gave him an opportunity to escape. The story ends with a final meeting between the Swiss hero and the governor in which Gessler was killed by Tell's arrow.

This story, which furnished the theme of Schiller's famous poetic drama *Wilhelm Tell* (1804) and of Rossini's opera *Guillaume Tell* (1829), is interwoven with the legendary history of the origin of the Swiss Confederation and the medieval Austro-Swiss struggles. It was first found in a ballad written before the sixteenth century. Early historians of the Swiss Confederation accepted the historical existence of Tell. Efforts were made by Aegidius (or Gilg) Tschudi and others to eliminate the inconsistencies and complete the story. According to Tschudi's *Schweizer Chronik* (1734-1736), Albert of Austria sent bailiffs to Uri and Schwyz to deprive them of their freedom; this produced an uprising on Nov. 8, 1307, and among the instigators was William Tell. The events of the Tell story took place on Nov. 18, 1307, and were followed by a general rising on Jan. 1, 1308. Since Joseph Kopp wrote a historical critique in 1835, historians have largely rejected the legends because of certain contradictions to known historical facts and because of the lack of agreement among the chroniclers themselves. Attempts were made as late as the 1930's, however, to use documentary sources to substantiate the existence of William Tell.

W. S. V.

**TELL** [tɛ′l], an Arab name for an artificial mound marking the site of an ancient city. In the ancient East it was usual to continue rebuilding on the same site. As the centuries passed and successive buildings were reared on the foundations and rubble of earlier ones, the levels of floors and streets gradually rose. In addition to collapsed walls of mud or sun-dried brick, rubbish and sand blown in from the desert helped to make the mound grow. Many of these ancient cities are abandoned, but some, like Erbil, the ancient Arbela, still crown their tells. By excavating tells layer by layer archaeologists are able to trace the development of architecture and of the arts and crafts of successive generations of city dwellers. In the Old World the most famous tells are found in western Asia, but analogous mounds are known from Greece and from parts of the Balkans. J. G. D. C.

**TELL CITY,** a city in Perry Co., in southern Indiana, situated on the Ohio River, 45 mi. east of Evansville. Coal mines and hardwood timber are in the vicinity. It is a retail trading center for the surrounding rural area of dairy, poultry, and stock farms. Tell City was settled by a colony of Swiss in 1857 and was laid out with a main street 80 ft. wide. It was named for the legendary hero, William Tell, and some of the manufacturers and merchants use as a trade-mark an apple pierced with an arrow. Tell City is governed by a mayor and council. The Southern Railway and river steamboats provide transportation. The chief local industry is woodworking. Pop. 1950, 5,735.

**TELL EL-AMARNA** or **AMARNA** [tɛ′l ɛl əmɑ′rnə], the capital of Egypt under Ikhnaton (Amenhotep IV: 1375-1358 B.C.), lies approximately halfway between Memphis and Thebes, occupying both sides of the Nile. It was founded to honor Aton, the sun-disk, whose worship Ikhnaton introduced to unify, if not replace, the old animal-headed Egyptian pantheon; this was the only attempt at monotheism Egypt ever made. The ancient name of the city was Akhetaton ("Horizon of Aton"), and all its contents were designed to please the god. Because of the historical certainty of the dates of its founding and abandonment, it is one of the most valuable archaeological sites in the world. The spacious city-plan is well preserved (excavations have been carried out by both German and British expeditions); it occupied an area about half a mile wide and two miles long, delimited by inscribed boundary-stones which are still to be seen, and contained royal palaces, fine villas, the great open temple of Aton, workers' quarters, and, beyond, the graves of its inhabitants. The city had wide tree-lined streets, many groves and gardens, and boating ponds.

Ikhnaton particularly emphasized "truth" in his new worship, as is evidenced in the well-known Hymn to the Sun. At the same time, a greater realism in art was encouraged, although how far this was also the result of foreign influences it is impossible to say. The clay tablets containing royal diplomatic correspondence found at Amarna show Egypt's many foreign connections, and the fact that this correspondence was carried out on both sides in Babylonian cuneiform further demonstrates the internationalism of the period. The gaily painted pavements of the King's palace, with their lively animals, fish, and plants, often seem Minoan in spirit, and the "flying gallop," a peculiarly Mycenaean convention, appears to confirm the source of this influence. Nofretete, Ikhnaton's queen, is generally supposed to have been a for-

eign princess, and one would like to think that she came from some part of the old Minoan realm. One of the most beautiful portrait sculptures of any country or of any age is the painted limestone bust of the queen in the Berlin Museum. Other fine sculptures, some strikingly realistic, were found at Amarna in the workshop of the sculptor Thùtmose.

We have many statues of Ikhnaton himself, in which the new naturalism sometimes seems extreme. The King appears to have been naturally ill-formed, with a paunch contrasting with his thin extremities, and a high, dome-shaped head; these peculiarities are not only faithfully rendered but often grossly exaggerated, and his courtiers and friends, perhaps from flattery but certainly not from realism, are depicted with the same physical defects. These appear in many tomb-reliefs from Amarna, where the King and Queen stand on the palace balcony, dispensing gifts to their subjects and worshipping Aton, a large sun-disk with rays, terminating in outstretched hands, streaming down upon his worshippers. The fresco in the Ashmolean Museum showing two of Ikhnaton's young daughters is charming in conception and composition, but the little girls are again pictured with their father's narrow shoulders, flabby paunch, and deformed head.

The influence of the Amarna School is still strongly apparent in the magnificent objects from the tomb of Tutankhamon, Ikhnaton's son-in-law, after whose reign Egyptian artists returned to their age-old conventions with scarcely a remembrance of the new approaches tried at Amarna.

Toward the end of Ikhnaton's reign, Egypt was in a weak position abroad, partly from Ikhnaton's neglect of foreign affairs in favor of his religious reform, and in internal disorder, partly as a result of the opposition of the priests of Amon (and perhaps of the populace as well) to the new religion. At the King's death, the new worship was rapidly abandoned, its works of art were obliterated wherever they could be found, the capital was returned to Thebes, and Amarna was left deserted. J. H. Y.

**TÉLLEZ, FRAY GABRIEL.** *See* TIRSO DE MOLINA.

**TELL HALAF** [tɛ'l hælɑ'f], an ancient settlement mound near Nusaybin on the Turkish side of the Turko-Syrian frontier, excavated by a German expedition in 1911 to 1913 and in 1929. Underneath a series of Hittite palaces with rich sculptures were found prehistoric levels. These yielded quantities of well-fired, hand-made pottery, comprising mainly bowls and flasks of a wide range of forms, decorated with polychrome painting. The paint, which is often shiny and includes black, red, orange, yellow, and white, was applied to a smooth cream or buff slip. Among the many distinctive designs were a number based on the heads of bulls and double axes. The pottery, which appears to have been manufactured in bulk in large domed kilns (examples were found at Arpachiya and Carchemish), was made in many regions of the Mediterranean, as at Mersin and Ras Shamra, and the Tigris, as at Tell Hassuna. It circulated among communities of a chalcolithic stage of culture, among whom stoneworking reached a high pitch of excellence but who were familiar with the casting in open molds of simple copper forms like flat axes and daggers. Other evidence of cultural advance is given by flasks and bowls of limestone and obsidian and by the wide-flung trade in pottery as well as precious substances. The appearance of stamp seals, engraved with distinctive patterns and looped for suspension on a cord, reflects the growth of personal wealth and commerce. J. G. D. C.

**TELL HASSUNA** [tɛ'l hæsu'nə], an ancient settlement mound twenty-two miles south of Mosul, Iraq. Excavation has revealed stages in the prehistoric settlement of Assyria from the Stone Age up till the period of metallurgy. The bottom yard of deposit showed three distinct levels of occupation, but no traces of solid buildings. No doubt the earliest settlers lived in tents or flimsy huts. Their culture was Neolithic. They fabricated polished stone axes, finely flaked tanged arrowheads, and hand-made pottery; they hunted wild animals, but their economy was mainly based on herding. Above this level, which represents the earliest settled culture in Assyria, there was a clear break, followed by seven yards of continuous occupation by agriculturalists, who, although using kohl and malachite as cosmetics, continued to depend on flint, stone, and obsidian for tool making. This thick accumulation can be divided into two parts: in the lower levels we find traces of the first mud huts together with incised pottery, like that already known from early deposits at Nineveh, and pottery painted with multilinear chevrons, like that from sites in northern Syria and southern Turkey, as at Mersin; in the later levels appear more elaborate houses, built round a courtyard and provided with elaborate baking ovens, in which the pottery is decorated with patterns in black paint on a pale ground like that from Samarra, farther down the Tigris. Above this, there occurred a second break in the occupation of the mound, followed by a phase in which polychrome pottery of Tell Halaf type appeared, together with seals, chariots, and copper axes and daggers. J. G. D. C.

**TELLURIDES** [tɛ'lyuraidz], a group of mineral compounds of gold and silver with tellurium. Most common tellurides are calaverite, $AuTe_2$, and sylvanite (Au,Ag) $Te_4$. These minerals range in color from silver white to steel gray. The simplest test for tellurium is to heat the mineral on charcoal in a reducing flame; tellurium colors the flame a distinctive bluish green. The tellurides are easily fused and roasted to obtain a gold button. Tellurium minerals are found in low-temperature hydrothermal veins. At Cripple Creek, Colorado, tellurides are the sole ore of gold. They occur in veins which ramify through the neck and flanks of a Tertiary volcano. Tellurides are occasional ores in other localities, including Ontario and western Australia. K. K. L.

**TELLURIUM** [tɛlʊ'riəm], symbol Te, atomic number 52, at. wt. 127.61, density 6.24, m.p. 452° C., b.p. 1,390° C. Tellurium (Latin *tellus,* earth) is the fourth member of Group VI-B of the periodic table, where it is preceded by oxygen, sulphur, and selenium and followed by polonium. Tellurium closely resembles sulphur and selenium, and it is widely distributed in nature, usually in small proportions. It is commonly associated with sulphur and selenium in the uncombined state; tellurides of gold, silver, lead, mercury, bismuth, nickel, and copper are found.

Tellurium forms grayish, lustrous, brittle crystals which are insoluble in water and carbon disulphide and conduct heat and electricity poorly. Tellurium burns in air, forming $TeO_2$, which is white and odorless and almost insoluble in water. Both tellurous acid, $H_2TeO_3$, and telluric acid, $H_2TeO_4$, are extremely weak. Tellurium and its compounds have few commercial uses. It is added to lead to increase its hardness, toughness, and resistance to corrosion; it also increases the life of rubber tires and imparts color to glass. B. S. H.

**TELLUS** [tɛ'ləs], an ancient Italian deity of earth, a goddess of marriage and fertility later identified by the Romans with the Greek Gaea. *See also* GAEA. G. E. D.

**TEMESVÁR.** *See* Timişoara.

**TEMNE.** *See* African Peoples.

**TEMPE** [tɛ′mpi], a city in Maricopa Co., in south central Arizona, situated on the Salt River, 10 mi. southeast of Phoenix. The city, originally called Hayden's Ferry, was founded by Charles Hayden and was incorporated in 1894. A health center and college community, it is the seat of Arizona State College and a state welfare sanitarium. The Gila River Indian Reservation is 10 mi. southwest of the city, which has transportation furnished by the Southern Pacific Railroad. Pop. 1950, 7,684.

**TEMPERA** [tɛ′mpərə], a method of painting in which solid pigments are mixed with water, and some kind of gum or gelatinous substance, usually the white of an egg, is then added to act as a binder. Pure tempera is invariably opaque, and colors are lightened by the addition of white pigment. The chief advantage of this medium is the durability and lasting brilliancy of the colors; the disadvantages are the fast-drying properties of the paint and the difficulty of blending colors on the paint surface.

Tempera was used for murals in ancient Egypt, and by Greek painters in the fourth century B.C. After this date it was used continuously as the standard method of painting in Europe until the introduction of oil techniques in the early fifteenth century. Thereafter tempera was combined with oil in a technique known as underpainting, in which a monochrome painting in tempera is first completed, the surface is then varnished, and finally color is applied by means of transparent oil glazes. This technique was used for virtually all easel painting until the seventeenth century.

Currently tempera is used as a fine art medium, and as a separate technique in a wide variety of fields, notably architectural rendering and advertising layouts, where its adaptability to use by the airbrush makes it especially suitable.

**TEMPERAMENT, MUSICAL,** an alteration in the pitch of notes in order to improve mistuned intervals. The most ancient tuning was described by the followers of Pythagoras in the sixth century B.C. In it the diatonic scale was tuned to pure octaves, which have a ratio of vibration frequencies of 2:1, and pure fifths, with a ratio of 3:2. This Pythagorean scale was advocated by Boethius in the sixth century of the Christian Era and was apparently the only tuning used in the Middle Ages. In this tuning the thirds (81:64) are very sharp. Such a note as G-sharp is higher than A-flat by the Pythagorean or diatonic comma, with a ratio of about 74:73. The Pythagorean tuning is excellent for melody but less satisfactory for harmony because of its sharp thirds. A violinist who tunes by pure fifths and who plays sharped notes higher than enharmonically equivalent flatted notes comes close to the Pythagorean ideal.

One of the tunings described by Claudius Ptolemy in the second century of the Christian Era had pure major thirds (5:4) as well as pure octaves and fifths. In it A-flat is higher than G-sharp, in contrast with the Pythagorean tuning, and the interval between the pure third and the Pythagorean third is the Ptolemaic or syntonic comma (81:80). Forgotten for centuries, this tuning was revived in the sixteenth century by Lodovico Fogliano (died c. 1539). It is generally called "just intonation." As applied to the complete chromatic octave, just intonation had two limitations. One was that notes could not be used in place of their enharmonic equivalents, so that if G-sharp was present, A-flat could not be, and modulation was limited to keys with two flats and three sharps. The second limitation was that certain triads within the above bounds, such as D-F-A, were unusable because of their dissonant intervals.

In order to equalize this second fault of just intonation, temperament was used. Pietro Aron (c. 1490-1545) recommended lowering each fifth by one-quarter comma, so that the major thirds (reached by four fifths, as C-G-D-A-E less two octaves) would be pure. This is called the meantone tuning or temperament, because in this system the interval C-D, for example, is precisely half the major third, C-E. As in just intonation, G-sharp is lower than A-flat in the meantone temperament. Although this temperament admirably solves one problem by substituting four small errors in the fifths for one large one in the third, it has the same limitations as just intonation with regard to modulation to the more remote keys. This tuning was intended primarily for keyboard instruments, such as the organ and the harpsichord.

Aristoxenus (fourth century B.C.) described somewhat vaguely a tuning in which the semitones are equal halves of tones, and he may thus be considered the forerunner of the sixteenth- and seventeenth-century writers who advocated equal temperament, in which the octave is divided into twelve equal semitones. The fifths of equal temperament are only slightly flat, but its thirds are quite sharp. G-sharp and A-flat in this system are, of course, the same note.

In the sixteenth century, equal temperament was used for fretted instruments, the lutes and viols of the time. During the seventeenth century it must have attained a certain vogue for keyboard instruments also, if its warm advocacy by Marin Mersenne (1588-1648) is taken into consideration. But not until after J. P. Rameau (1683-1764) had advanced the theory and J. S. Bach (1685-1750) had furthered its practice by writing *The Well-Tempered Clavier* did equal temperament gain general acceptance for keyboard instruments. Even so, organs retained their old, unsatisfactory tuning longer than did pianos.

Equal temperament is presumably the tuning that every one accepts today. Brass instruments still have tendencies toward just intonation, however, and strings toward the Pythagorean tuning; piano tuners, besides, are not infallible; and as long as these conditions persist, it is clear that equal temperament cannot strictly be said to be in universal use.

**TEMPERLEY, HAROLD WILLIAM VAZEILLE** [tɛ′mpərli] (1879-1939), English historian, was born in Cambridge on Apr. 20, 1879, and was educated at Sherborne School and at King's College and Peterhouse, Cambridge. He was a fellow of Peterhouse and tutor in history there from 1904 to 1938, when he was elected master of Peterhouse. He lectured at Cambridge first as reader in modern history and then, from 1937, as professor in the newly created chair in that subject. He also lectured at Harvard (1911-1912) and Stanford (1936), and was Ford Lecturer at Oxford (1937-1938). He was president of the International Historical Congress from 1933 to 1938. After serving during the first World War in the Dardanelles and at Salonika, Temperley became a member of the Allied mission to Montenegro and of the Albanian Frontiers Commission (1921). As the official English historian of the Peace Conference, he edited *A History of the Peace Conference of Paris* (6 vols., 1920-

1924). Among other important works are *Life of George Canning* (1905), *Frederick the Great and Kaiser Joseph* (1915), *History of Serbia* (1917), *The Foreign Policy of Canning* (1925), *British Documents on the Origins of the War* (ed. with G. P. Gooch, 11 vols., 1926-1938), *England and the Near East* (Vol. I, *The Crimea*) (1936), *Foundations of British Foreign Policy, 1792-1902* (1938), and *A Century of Diplomatic Blue Books* (1939). A sound scholar, he was undoubtedly the leading English authority on modern diplomatic history. He died at Cambridge on July 11, 1939.

E. R. A.

**TEMPEST, THE** (1611), a tragicomedy by Shakespeare, probably the last play attributable to his sole authorship. The theme—a storm, a shipwreck, and the adventures of the shipwrecked party on an enchanted island—was suggested to Shakespeare by the reports received in London late in 1610 of the wreck of an English ship off the Bermudas and the unexpected survival of her crew after a winter's sojourn in those islands. It was a topic for a timely play, but it had little or nothing of a plot. Somewhere, however, in old stories and in Italian comedies Shakespeare picked up accounts of a banished prince who was also a wise magician. This sage had a fair daughter whom he contrived to marry to the son of a hostile king in order to end an old feud. This action and these characters, magician, daughter, prince, and king, Shakespeare set in an enchanted island after a shipwreck, and the result was *The Tempest.*

The plot of *The Tempest,* which alone among Shakespeare's plays observes the unity of time, is one of the author's slightest. In spite of its lack of exciting action, however, *The Tempest* contains something for all tastes: lovely songs; a stately masque, with music and dancing; spectacles that must have taxed the resources of the Blackfriars stage; the farcical comedy of Caliban, the drunken butler and the jester; the love story of Ferdinand and Miranda; and, controlling and directing all, the figure of the wise and benevolent magician Prospero. All this is for the theatre; for the thoughtful reader there is more: the ineffable beauty of the verse; the serene wisdom of the thought, with its insistence on repentance and reconciliation; and, above all, the haunting sense that this play may be the master's farewell to the art with which he had wrought such wonders. The famous lines given to Prospero, beginning with the words, "Our revels now are ended," seem to utter Shakespeare's final judgment on man's little life.

**TEMPLARS, KNIGHTS.** *See* KNIGHTS TEMPLARS.

**TEMPLE, HENRY JOHN.** *See* PALMERSTON, 3RD VISCOUNT (HENRY JOHN TEMPLE).

**TEMPLE, SIR WILLIAM** (1628-1699), English diplomat and man of letters, was born in London in 1628 and was educated at the Bishop Stortford grammar school and at Emmanuel College, Cambridge. In 1655 he married Dorothy Osborne, who became a famous letter-writer. He embarked on his diplomatic career in 1665 under the patronage of Lord Arlington, who sent him as envoy to the Bishop of Münster. From Münster he was sent to Brussels, and it was during this mission that he negotiated in 1668 the famous Triple Alliance between England, Sweden, and the Netherlands, which was designed to curb the ambitions of Louis XIV. This was followed by his appointment as English ambassador at the Hague, a position he held until 1670, by which time his policy of friendship with the Dutch had become unpopular with the English government. He went back to Holland as ambassador in 1674 and arranged the marriage between William of Orange and Princess Mary. Returning to England in 1679, he retired two years later from politics and in 1686 settled at Moor Park, his country house in Surrey.

Temple's literary efforts consisted chiefly of memoirs (published in two parts in 1691 and 1709), essays (published in *Miscellanea,* 1680, 1692, 1701), and a few longer pieces such as the *Essay on the Original and Nature of Government* (1672). His essay *Upon Ancient and Modern Learning* was attacked by Richard Bentley and so occasioned a famous literary quarrel, in which Temple had the spirited support of his young secretary, Jonathan Swift. Temple's essay *On Gardens,* written on a subject that was especially congenial to the author, is considered a classic in its kind. His prose, especially in his shorter compositions, is cadenced, gracious, and simple. Temple died at Moor Park on Jan. 27, 1699.

E. R. A. and T. B. S.

**TEMPLE,** a city in Bell Co., east central Texas, located near the Leon River, 35 mi. south of Waco. It was founded and incorporated in 1881 by the Gulf, Colorado and Santa Fe Railroad, which with the Missouri-Kansas-Texas Railroad provides transportation. The city of Temple has the city-manager form of government. The city's hospitals, including a veterans' facility and the Gulf, Colorado and Santa Fe hospital, are noted throughout the country. There is a junior college located in Temple. Farming is the principal pursuit of the district, and cotton, corn, and oats are the main crops. The city's industrial establishments include railroad shops and furniture, rock wool, and men's clothing factories. Pop. 1950, 25,467.

**TEMPLE** (Heb. *beth ha-mikdash*), in Jewish history, the name of the two successive central sanctuaries of the ancient Hebrews. The first of these, which is described in detail in I Kings (vi-vii) and again in II Chronicles (ii-iv), was built by Solomon in Jerusalem, on a site originally purchased by his father David (II Sam. xxiv: 18-25). Solomon's alliance with Hiram, king of Tyre, enabled him to procure Phoenician artists, builders, and materials, and the magnificent structure that resulted was the work of seven years.

According to Biblical tradition, Solomon's Temple replaced the Tabernacle as the Hebrew house of worship. The Tabernacle, minutely described in the Book of Exodus (xxv-xxviii; xxx-xxxi; xxxv-xxxix), was the portable sanctuary of the Hebrews during their sojourn in the wilderness. After their entry into Canaan, it was set up at Shiloh. There are marked similarities in the arrangement of the Tabernacle and that of the Temple, and presumably the latter was modeled on the former. In the opinion of most Bible critics, however, the reverse is probably true, for they regard the conception of the Tabernacle as a projection into the past of post-exilic ideas, and accordingly, the description of the tabernacle, which is ascribed to the priestly school of writers, reflects the impression made by the First and Second Temples. An interesting comparison may be made between the house of the Lord envisioned by Ezekiel (Ezek. xl: xlv) and the Tabernacle and the two Temples.

The appointments of Solomon's Temple were of great value, and several times during its four-hundred-year existence the Temple was plundered by enemies. Hezekiah, king of Judah, was obliged to take silver and gold from the Temple to pay tribute to the king of Assyria (II Kings xviii:13-16). In 586 B.C. the First Temple was destroyed by the Babylonians, Nebuchadnezzar carrying off its vessels to Babylon.

**Second Temple.** When the Jews returned from the Babylonian exile (536 B.C.), they erected an altar on the site of the destroyed temple and laid the foundation for the new

one, Cyrus of Persia having given permission for its erection. The work was temporarily discontinued, however, either because of outside interference (as suggested in the Book of Ezra) or because of apathy on the part of the people (as suggested in the prophetic books of Haggai and Zechariah). Work was resumed (520), apparently in obedience to the exhortations of the two prophets, and in 516 B.C. the Second Temple, also called Zerubbabel's Temple, was completed. This building, although similar in general arrangement to Solomon's Temple, could not compare with it in magnificence. During the period of the Second Temple priestly influence was strong in Jewish thought, and the temple ritual was therefore extremely elaborate. The Temple was desecrated by the Syrians under Antiochus Epiphanes in the second century B.C. and was cleansed and rededicated by Judas Maccabeus.

**Herodian Temple.** In the eighteenth year of his reign (c. 20 B.C.), King Herod set out to renovate and rebuild the Temple. He greatly enlarged the building itself and the whole surrounding area. The reconstructed building, lavishly adorned with gold and silver, was, in its time one of the most splendid edifices in the Near East. The renovation of the Temple proper was completed in a year and a half, but the work on the outer structures continued until the Temple was burned by the Romans in A.D. 70. All that remains is a portion of the western side of the outer wall that enclosed the Temple area; this wall, which gives some suggestion of former magnificence and size, is known as the Wailing Wall, and pilgrimages are made to it and prayers offered there. The hope that the Temple will be restored is part of the messianic aspirations of traditional Judaism. *See also* ARK; HANNUKAH; JERUSALEM; TISHA B'AB. M. A. G.

**TEMPLE, CLASSICAL.** In Classical antiquity the temple had a place not only in the interests of individual citizens but also in the functions of the civic body. Being an expression of the aims and resources of the state, it stimulated and conditioned some of the most characteristic manifestations of Classical architecture and its dependent arts. As thus interpreted, a temple differed in degree rather than in kind from palace sanctuaries such as those of the Bronze Age in Crete, or a house- or street-shrine with its associations with small social groups, for which abundant evidence is available from Delos and Pompeii. From another point of view, the temple represented the culmination of the urge to propitiate the supernatural energies, a consciousness of which was stimulated in primitive man by such natural landscape features as hill-tops, groves, caves, springs, and large, mysterious stones. The graves of the dead were also important centers of propitiatory ceremonies.

It was usual throughout the Greek and Roman world that the temple building proper should be treated as the shelter for the image of the Divinity, and that the act of worship should be performed outside it, at an altar that normally was placed in front of and on the axis of the sacred building. At certain sanctuaries, the Athenian Acropolis and the sacred grove of Olympia, for example, this altar lay off the axis, an indication that its foundation antedated that of the temple building itself, and by inference that it originated in an age that did not represent the divinities in human form. Most temples in Greece, and some in Roman areas, were placed in enclosures that isolated them from contact with the workaday world and within which various forms of accessories for the cult were provided. When Augustus constructed the great Temple of Mars Ultor and its "forum" in a crowded part of Rome, he observed this tradition, erecting a lofty fireproof wall, partly in a spirit of conservatism, partly from practical considerations. An important divinity, as patron and protector of the state, would naturally be housed at the summit of the citadel, as Athena on the Acropolis of Athens, and Jupiter Optimus Maximus, Juno, and Minerva on the Capitoline Hill in Rome.

The foundation, or at least the maintenance, of a temple was frequently dictated by considerations of a utilitarian character: this appears in the plainly recognizable class of "promontory-temples" that marked the principal sea routes of early times. The divinities that presided over wind and weather required propitiation along those routes; hence, there existed such well-frequented shrines as those at Sunium, the critical point for mariners approaching Athens from the east, and at the wind-dividing cape near Croton, on the route towards the western waters. Temples at health-giving springs became associated with the medical art, as at Epidaurus, Cos, and Pergamum, and the accumulation of offerings led to the local priesthood's assuming some of the functions of custodians and bankers, doubtless furthering the invention and development of coinage. A still more profound influence in the Greek world was exerted by the far-famed and revered oracular sanctuaries, such as that at Delphi, which, being frequented by pilgrims from all parts of the Greek world and the regions adjacent, placed the priesthood in possession of unrivalled information, which they used effectively, for instance, in giving advice as to the establishment of colonies in remote parts of the known world. The recurring festivals at some religious centers, such as Olympia and Delphi, brought the various branches of the Greek race together as nothing else could, and exerted incomparable influence on the arts. Athenian tragedy and comedy grew up in connection with the sanctuary of Dionysus, "the Liberator," and the other sanctuary of Dionysus "in the Marshes," for which special theatrical edifices were created. The drama, like song and dance, was a ritual act, at least in its origins and by its traditions.

In the Roman world, given the practical and administrative tendency of that people, the chief temples served the cults and the functions of the State often in a matter-of-fact way. First, the kingdom witnessed the building of the Capitoline temple, which was inaugurated in the first year of the Republic; then followed the various forms of worship of the Republic, including the dramatic representations held at the festivals; and finally, the temples became associated with the worship of the rulers, the Imperial House, and the Imperial administration. The worship of the administration became the special function of temples in the provinces; in certain regions, notably, Gaul and Britain, a contrast was afforded by nonclassical types of structure, which testify to the persistence of the traditional regional culture. In the smaller communities of the Empire, temples, like baths, afforded an opportunity to wealthy benefactors to perpetuate their names by the donation of such structures; but expenditures of this kind occurred too frequently and uniformly to have been purely spontaneous and voluntary, and in reality these benefactions, which discharged to some extent the responsibilities of whole communities, were the equivalent of a graduated tax on wealth.

The intelligence and imagination of the Greeks, Etruscans, and Romans found expression in their temples. Classical Greek temples provided for a cult statue in human form in the midst of the main room, within which it could be seen from all sides, an anthropomorphic and tridimensional figure; the Etruscans set their images against the back wall of the sanctuary, which they treated as a spiritual or metaphysical

medium to collect and send forth the waves of supernatural emanation; the Romans, again with their practical leanings even in religious matters, and with their legalistic bent towards formalization and codification, placed their temples, by preference, not in walled-off areas but at their civic centers and in direct contact with the administrative, commercial, and social activities for which they were made to function. In the Roman Forum the basement of the Temple of Saturn accommodated the state treasury, and that of the Temple of Castor and Pollux held a series of well-protected cells which appear to have served as strong rooms as well as a bureau of weights and measures, while its front was used at times as a platform for speakers, and the temple was always the rendezvous of the Roman knights. By reason of their ritually "inaugurated" status, some of these edifices were on occasion chosen for meetings of the Senate.

The Latin word *templum* has technical associations due to the tendency of the Roman mind to approach its problems through the use of formulas, whether verbal or mathematical, and through the reduction of the abstract and nebulous to the concrete and precise. It is in origin a term in augury, meaning "that which is marked off or defined." From signifying the augur's rectangular hut or tent, and the rectangular space about it, which served as starting point or base for his observations of earth and sky, it was applied to the ground, likewise rectangular, set apart by augury for a consecrated edifice, whether a shrine or an administrative building. The Roman senate-house, according to the learned Varro, contained a *templum* in the sense of a defined space within which decrees of the senate might lawfully be promulgated. Then, through association, the word was used to denote a religious edifice, first one that had been "inaugurated" by augury, then even those belonging to other categories; so that in many instances its meaning cannot be distinguished from that of *aedes* ("building"), especially in the works of the poets, for whom metrical convenience appears frequently to have determined the choice of the one word rather than the other.

The temples of classical antiquity are now represented by the actual remains, in varying degrees of preservation, of some hundred edifices in Greek lands, over seventy from Etruria or the Roman Republic, and a vast number belonging to the Roman Imperial period, in Rome itself, Italy, or the provinces. For their interpretation, much help is afforded by building inscriptions, inventories, and records of various sorts; by the technical treatise of Vitruvius, who very wisely starts his discussion by emphasizing the importance of "symmetry" and "proportion"; and by innumerable passages in literature, as well as representations on coins and in sculpture. The following account is summary and selective, but will endeavor to show the general features and broad tendencies of temple construction.

The conventional design shows the essential elements in a fully developed Greek temple: a rectangular plan and a nucleus enclosed between side walls, with columns between pilasters at one or both ends. Such a nucleus was typologically and functionally complete in itself, but in the larger structures it was usually enclosed by a colonnade. The series of temples began in the sixth century B.C. at Thermon and Sparta and reached its perfection in the Age of Pericles at Athens. Both forms and decoration were influenced by the traditional use of sun-dried brick, with wooden roofing and the protection of roof-tiles and cornices of clay. A logical ordering of the various parts was maintained throughout the centuries. Evolution was in details and refinements, and in the adoption of richer materials. In most parts of the Greek mainland, as well as in southern Italy and Sicily, the Doric order was followed; in Asia Minor, the Ionic. Ictinus, the architect of the Parthenon and the temple at Phigalia, used both, in different parts of his temples, and even introduced an early form of Corinthian column at Phigalia.

In Hellenistic times this rich, slender early form of the Corinthian column, which had certain practical advantages, achieved the vogue that it held under the late Roman Republic and the Empire. The solid, spacious, and approachable character of the Greek temple was aided by its low, stepped foundation and by its colonnade; its visual effectiveness was increased by the deep shadows cast by the colonnade and by the contrasts afforded by the simple coloring in certain upper details, especially the fields of metopes and friezes, and the cornices and eaves. It was relieved of possible monotony by various devices and subtleties, such as the adjustments in intercolumnar space necessitated at the corners of a Doric temple through the problem of the corner metopes and triglyphs; also through the delicate modifications in the contours and proportions of shaft and capital. Some of the most carefully constructed temples show slightly convex instead of horizontal surfaces, a structural and optical subtlety that surely was intended by the builders. The danger of earthquakes prompted the exercise of great pains in ensuring the stability of the foundations. The lighting of the interior was limited to the front opening. There was a tendency in practice to use the pronaos for the exhibition of votive offerings, and the opisthodome for more protected storage of similar objects. Round buildings, like those at Olympia, Delphi, and Epidaurus, while exhibiting perfection of craftsmanship, are not temples of the greater divinities.

The Etrusco-Italic temple, while making use of many of the achievements of the Greeks, was motivated by a different conception of the deity and of the use to be made of his shrine. It stood upon a lofty base; the depth of its front porch was commensurate with that of the cult room behind, and its rear wall, which frequently extended on each side beyond the lines of the side walls of the cult room, served as backing for the cult image. The main features of the Etrusco-Italic temple appear in the remains of the temple at Lanuvium in Latium. Several of these edifices have a triple cult room, like that of the Capitoline Temple in Rome. The walls and roofings of most of them were executed in perishable materials, wood and sun-dried brick, and this necessitated or encouraged the use of terra-cotta revetments, a Greek or Near Eastern device, which was here accorded a special interpretation. These edifices also reveal a distinctive treatment of the pediment, its *columen* and *mutuli* masking the ends of the main and secondary roof-beams.

The Romans, in temple building as in other matters, availed themselves of the achievements of the Greeks and of the traditions of the Etruscans and Italians, but adapted them to their own requirements. They sometimes applied the space available in the high substructure to practical ends, inserting a platform for the altar between the flights of stairs at the front. Augustus performed a great work of restoration, using the old formulas conservatively, but carrying them out in the costly white marbles of Greece and Luna (Carrara); the characteristics of his age appear in the *Maison Carrée* at Nîmes in France. Succeeding generations witnessed the development of methods of construction in brick and concrete, with facing in marble or stucco, and, in spite of occasional Classicistic revivals, a turning away from the Greek tradition in favor of a more truly national and Imperial mode of procedure. The niche at the rear of the cult room was added as a new element, and the apse was further developed. Meanwhile an independent, parallel course was run by another Italic type

of structure, the round shrine, the best-known example of which was the sanctuary of Vesta in the Roman Forum, and the most monumental expression the Pantheon as rebuilt by Hadrian. The circular shape of the sanctuary and the Pantheon appears to exclude them from the category of *templa* in the strict sense, though this word as well as *aedes* is applied by the poets to the shrine of Vesta. The Pantheon appears to stand in a class by itself with regard to its religious functions, and other round buildings may have been dedicated not to the great divinities of the celestial hierarchy but to secondary, subordinate members, such as Hercules and Portunus. With the later Empire and the influx of Oriental religions, a further shift occurred in cult requirements, and there came an urge to vastness of dimension. Concomitantly, the spread of the worship of Mithras led to the establishment of numerous diminutive shrines of that god in all parts of the Empire, and especially at frontier posts, though they are well represented at Ostia and in Rome itself. When the reign of Constantine (A.D. 307-337) brought official recognition of Christianity, a different attitude towards the divine and a different ritual found monumental expression: a new age began. A. W. Van B.

**TEMPLE UNIVERSITY,** an accredited, coeducational, privately controlled institution, partially supported by state aid. The university occupies a 71-acre campus within the city limits of Philadelphia, Pa. It was started in 1884 and was chartered four years later as Temple College. The present name was adopted in 1907, when the professional schools were added.

The degrees offered include the A.B., the B.S. in metallurgy, business administration, education, pharmacy, theology, and medical technology. The M.Ed., the M.S., the M.D., the D.D.S., the L.L.B., the M.S. and D.S. in chiropody, the M.S.T., the D.S.T., the M.A., the D.Ed., and the Ph.D. are also awarded. The divisions of the university include the College of Liberal Arts and Sciences (1888), the School of Theology (1893), the School of Law (1895), the School of Medicine (1901), the School of Pharmacy (1903), the School of Dentistry (1907), the School of Music (1913), the School of Chiropody (1915), the School of Commerce (1918), Teachers College (1919), the School of Oral Hygiene (1920), the Oak Lane Country Day School (1931), the Stella Elkins Tyler School of Fine Arts (1935), and the School of Nursing (1937). A Community College and Technical Institute has recently been established to provide for junior-college work and for a two-year vocational college to offer university facilities to business, industry, and labor unions, including management and labor service. The university library contains a collection of books printed in England prior to 1550 (film copies).

Sororities and fraternities have been established on the campus and the students are permitted to live in the chapter houses. Dormitories are available and any other housing must be approved. Scholarship assistance is very generous and a substantial fund has been established to grant loans to students. *For statistics see* COLLEGES AND UNIVERSITIES. J. R. To.

**TENAFLY** [tɛ′nəflai], a borough in Bergen Co., in northeastern New Jersey, situated on the Hudson River, 17 mi. north of Jersey City. Transportation is provided by the Erie Railroad. Tenafly is a residential community with a few light industries. The borough was founded by the early Dutch and French Huguenots, and incorporated in 1894. A mayor and council administer the local government. Pop. 1950, 9,651.

**TENANT.** *See* LANDLORD AND TENANT.

**TEN BRINK, BERNHARD AEGIDUS KONRAD.** *See* BRINK, BERNHARD AEGIDUS KONRAD TEN.

**TENCH,** *Tinca tinca,* an Old World minnow of the family Cyprinidae. Ranging through Europe, Asia Minor, and western Siberia, it inhabits weedy ponds, reservoirs, and sluggish rivers. The tench lives near the bottom and feeds on worms, insects, shellfish, and weeds. In winter hibernation, it burrows in the mud. Some of them dredged from the bottom at this time showed no life until struck several times. A very hardy fish, the tench may live a fairly long time out of water and survive periods of drought by burrowing in mud. A person, making a quiet approach and slipping the fingers under the gills, can often catch a tench by hand. Full-grown specimens reach a weight of over 12 lb. A generally discredited idea that this fish has healing powers, both for other fish and men, was formerly widely believed in Europe. E. C. R.

**TENEBRAE** [tɛ′nɪbri] (Lat., darkness), in the Roman Catholic Church, the anticipated office of matins and lauds of the last three days of Holy Week. The gradual putting out of the lights in the Good Friday office dates probably from the fifth century, Thursday's office being said in a brightly lighted church, and Saturday's with a single candle. This extinguishing of the lights, symbolic and not simply utilitarian in origin, was extended to all three offices, which came to be regarded as a sort of solemn dirge commemorating the death of Jesus Christ. Among the texts chanted are the Lamentations of Jeremiah. Upon the unadorned altar are set six candles, and upon a hearse or harrowlike triangular frame, fifteen more. Of these fifteen, one is put out at the end of each of fourteen psalms, the six on the altar being extinguished during the *Benedictus.* The remaining lighted candle is then hidden behind the altar. The words "Christ became obedient for us unto death" are sung, Psalm 50 is recited, and a prayer said. The candle is then brought forth. The making of "a noise and clatter to some extent" originated in the master of ceremonies' signal to leave, and was later interpreted as a symbol of nature's confusion upon the death of Christ. N. J. T.

**TENEDOS** or **BOZCAADA** [tɛ′nədos, bo′zjɑɑdɑ′], a Turkish island, about 6 mi. long and 3 mi. wide, and also the chief town of that island, lying in the Aegean Sea, 3 mi. off the west coast of Asia Minor and 12 mi. south of the entrance to the Dardanelles. Because of its location, the island has a historical importance entirely disproportionate to its size. In the Trojan legend it played a prominent part as the station to which the Greeks withdrew and concealed their fleet, after leaving the wooden horse at the gates of Troy; and during the Persian wars the island was used by Xerxes as a naval base. In the Peloponnesian War, Tenedos sided with Athens, to which it paid tribute; but at the peace of Antaleidas it was surrendered to the Persians. In the time of Alexander the Great, the Tenedians revolted from Persia; and during the wars of Macedonia with the Romans the island was again an important naval station. The emperor John V Palaeologus ceded Tenedos to the Venetians in 1377, and in 1657 the island was seized by the Turks and permanently incorporated into the Turkish Empire. The popula-

tion of the island is mostly of Greek origin. Tenedos produces excellent wines and in ancient times was noted for the beauty of its women. Pop. 1950, 1,781. C. W. D.

**TENERIFE** [tɛ′nərɪf; te′neri′fe], a volcanic peak, the highest of the Canary Archipelago, on the island of Tenerife, occupying with its spurs nearly two thirds of the island. Its gullies and escarpments descend to the coast. The volcano is not extinct, though normally it is quiescent; continuous steam and sulphurous vapor issue from it. It has two craters: El Piton, about 12,192 ft., and Chahora, about 9,888 ft. The base of the cone is covered with good pasture, succeeded by chestnut, oak, and pine forests. The upper slopes are covered with slaggy lava, and the peak is snow-covered for four months of the year. A climatic vagary of the area is that the peak is often swept by a strong antitrade wind from the southwest, while the northeast trade wind is blowing at the base. In the years 1761, 1795, and 1798, great quantities of lava poured from the crater and vents in the mountain. The last serious eruption occurred in 1910.

**TENGGERESE.** *See* Indonesian Peoples (*Principal Peoples*).

**TENGRI KHAN** [tɛ′ŋri χɑ′n], the highest peak in the central Tien Shan range, on the border between the Kirghiz Soviet Socialist Republic of the Soviet Union and Sinkiang. The height of the peak is estimated to be 22,940 ft. Tengri Khan is at the point where the long, high Ala Tau and Kok Chaal ranges meet. On its western side, the mountain has at least five glaciers exceeding 12 mi. in length. The longest of these is the Inyltchek Glacier, which exceeds 46 mi. in length. J. E. V.

**TENIERS, DAVID** [təni′rs] (1610-1690), called "the Younger," Flemish genre painter, was born in Antwerp in 1610, the son of the painter David Teniers "the Elder," from whom he received his first training. In 1637 he married the daughter of the painter Jan Brueghel. In 1646 he was appointed court artist and director of the picture gallery of the governor of the Netherlands, and in 1663 he founded a painting academy at Antwerp. Teniers' pictures won the high esteem of both Philip IV of Spain and Louis XIV of France, and he became the most successful and prolific genre painter of Flanders in the seventeenth century. As many as two thousand paintings have been credited to him. His earliest peasant scenes were influenced by Rubens and Brouwer, but about 1640 he developed a strong, original style, characterized by treatment of light and shade with facile brushstrokes of bright but cool colors. The quality of his work varies greatly. His importance and popularity rest on tavern and outdoor scenes of merry, salubrious peasant life, though he also depicted mythological, religious, and historical events. Teniers died in Brussels on Apr. 25, 1690. R. A. K.

**TENINO.** *See* Indian Tribes, North American (*Plateau*).

**TENITE.** *See* Plastics (*Commercial Plastics*).

**TENNESSEE,** a central southeastern state of the United States. The meaning of the word is unknown but is said to have been derived from Tannansie or Tansi, the name of the ancient capital of the Cherokee tribe, which later became the name of both the state and the Tennessee River; the name was first used in its present form in 1761. Tennessee has been known as the Volunteer State since the Mexican War, when a call was issued for 2,800 men and 30,000 volunteered. It has an area of 42,244 sq. mi., of which about 285 sq. mi. are inland water surface. It ranks thirty-third in area among the states. The state has the form of a rough parallelogram. It is bordered on the north by Kentucky, on the northeast by Virginia, on the east by North Carolina, on the southeast by Georgia, on the south by Alabama, on the southwest by Mississippi, and on the west by the Mississippi River, which separates it from Arkansas and Missouri.

Tennessee entered the Union on June 1, 1796, and was the sixteenth state to achieve statehood. Its motto is "Agriculture, Commerce." The state flower is the iris; the state bird is the mocking bird; and there are two official state songs, *My Homeland, Tennessee* and *When It's Iris Time in Tennessee.* Tennessee has ninety-five counties, and the state capital is Nashville.

## PHYSICAL FEATURES

**Topography.** The surface features of Tennessee are highly varied. They range from the rugged mountain country on its eastern border to the flat swampy plains of the Mississippi River on the west. There are roughly three grand divisions—east, middle, and west—each varying slightly in climate and agriculture. The mean elevation of the state is around 900 ft., with its highest point at Clingman's Dome, 6,642 ft., in the Great Smoky Mountains National Park of east Tennessee, and its lowest point, 190 ft., just south of Memphis on the bank of the Mississippi River.

*THE GREAT SEAL OF THE STATE OF TENNESSEE*

COURTESY OF THE TENNESSEE CONSERVATION DEPT.

The eastern border of Tennessee runs along the crest of the southern end of the Appalachian Mountains, known in this section as the Unaka Range. This range includes the Great Smoky Mountains, from which the National Park takes its name. All sections of the Unakas, outside Great Smoky Mountains National Park, make up the Cherokee National Forest. The Unakas consist of a chain of complicated and irregular crystaline ridges, and of small mountain coves. The coves are isolated, fertile valleys. The Unakas vary in width from about 2 to 15 mi., and the main peaks, which lie along the central section of the state's eastern border in Great Smoky Mountains National Park, are more than 6,000 ft. high.

This range drains into the valley of east Tennessee and the Tennessee River, which has now become a series of man-made lakes. The valley floor, varying from 30 to 60 mi. in width, is cut by a series of parallel low ridges and valleys, the ridges lying as high as 800 ft. above the general valley floor.

The eastern edge of the Cumberland Plateau is a south-

ward continuation of the Allegheny Front, rising about 1,000 ft. above the level of the east Tennessee valley. The southern portion of this eastern face, known as Walden Ridge, is sharp and abrupt. The upland surface of the plateau has an elevation of about 2,000 ft. and is somewhat dissected, in the south by the Sequatchie Valley and in the north by many deep, narrow valleys separated by sharp dividing ridges. The western escarpment of the plateau is also generally precipitous.

The Highland Rim bounds the Cumberland Plateau on the west and lies about 1,000 ft. below it. The Rim is part of an old dome which has been eroded in its central portion, exposing an area known as the Nashville Basin. Its inward margin, fronting on the basin, is sharply dissected by stream erosion, and the fringe is known as the Knobs.

The Nashville Basin, which lies about 400 ft. below the general level of the Rim, is a fertile limestone region extending nearly the entire breadth of the state from northeast to southwest. It is about 120 mi. long and 60 mi. wide.

The Plain of Western Tennessee comprises the broad region west of the Highland Rim. It includes the western valley of what is now Tennessee-Kentucky Lake, the largest man-made body of water in the world. Also included is the Jackson Plain, stretching westward to the Mississippi River. The Jackson Plain is a rolling region moderately dissected by sluggish streams. It ends abruptly on the west in a line of low bluffs, cut by the Mississippi in its meanderings across its flood plain.

The Mississippi Bottomlands comprise a narrow strip of flood plain extending from the western limits of the Jackson Plain to the Mississippi River itself. This region, consisting of low swampy plains, varies in width with the bends of the river and contains many small lakes and ponds. Reelfoot Lake is close to the northwestern border of the state.

**Drainage.** The entire state of Tennessee drains directly or indirectly into the Mississippi River and thence into the Gulf of Mexico. The eastern part of the state is drained by the Tennessee River and its tributaries. All streams of the east Tennessee mountains, regardless of their original direction of flow, eventually turn west and flow back into the Tennessee River. The northern part of the state drains through the Cumberland River into the Ohio River. The central section drains into the western leg of the Tennessee River. The Jackson Plain drains directly into the Mississippi through a number of small rivers.

**Climate.** Tennessee has wide variance in climate and seasonal changes between the mountains of the east and the lowlands of the west. Average winter temperatures are relatively low, ranging from a high of 42° F. in the southwest to a low of 34° F. in the east. Zero temperatures occur occasionally in the lowlands, but more frequently in the highlands, where winter temperatures occasionally drop considerably below zero. Summer temperatures are normally warm to hot, with an average for the state of about 76° F. Western and middle sections of the state will average in the eighties during the summer, with occasional rises to 100° F. or above; 70° F. is an average for the mountains of the east. Tennessee's average annual precipitation is approximately 50 in., but the mountains of the east sometimes know as much as 80 to 100 in. in a year. Heaviest rainfall occurs in late winter and early spring. The state average for snowfall is about 9 in., though often there is heavier snowfall in the eastern mountains. Snow rarely remains in Tennessee longer than a few days. The state has an average growing season of from 190 to 200 days.

**Soils.** The soils of Tennessee vary greatly. Their fertility depends largely on the character of the underlying rock and upon slope and drainage conditions. In the eastern mountain region the soil is generally thin, stony, moderately acid, and of low utility. However, in this region, the coves, because of their limestone parent materials, are highly fertile. The soils of the Tennessee Valley in eastern Tennessee are moderately fertile. The Cumberland Plateau and the inner margin of the Highland Rim have, for the most part, thin, porous, unproductive soils and are considered the poorest agricultural areas in the state. The finest soils are found in the Nashville Basin, where the limestone bedrock and its blue-grass covering have produced deep, rich soils high in organic and mineral matter. The Jackson Plain is moderately fertile except in its more rugged portions. On the west, the Mississippi Bottomlands, composed of fine alluvial sands, silts, and clays, are highly fertile and give excellent yields where drainage conditions warrant their use.

EWING GALLOWAY

*The Chimneys, twin mountain peaks in the Great Smoky Mountains National Park*

**Fauna.** The principal animals found in the state are black bear, deer, bobcat, red and gray foxes, raccoon, opossum, skunk, gray squirrel, ground hog, and cottontail rabbit. The wild Russian boar has long been settled in the Cherokee National Forest, and many game birds and animals are frequently restocked. Birds in the state include the mocking bird, bald and golden eagles, northern raven, great blue and green herons, wild turkey, ruffed grouse, quail, robin, bluebird, killdeer, meadow lark, cardinal, towhee screech owl, red-tailed and sparrow hawks, Carolina chickadee, whippoorwill, flicker, woodpecker, and Carolina wren.

Waters throughout the state are well stocked with large- and small-mouth bass, striped bass, catfish, jack salmon, wall-eye, red-horse, spoonbill, crappie, bream, and carp. Though all the large lakes abound in game and other fish, the State Department of Conservation and the T. V. A. stock many streams and small ponds with hatchery fish.

Among the common reptiles of Tennessee are turtles,

frogs, lizards, and thirty kinds of snakes. The rattlesnake, the copperhead, and the cottonmouth moccasin are poisonous. The rattler, known as the diamondback, is found throughout the state, in wooded areas, in rocks near timber, and on the lower balds of the Smokies. Copperheads are usually found in bushy regions, moccasins in or near the water. The swift black snake often grows to a length of seven feet. King snakes, both scarlet and brown, are common to all sections of Tennessee and are deadly to all poisonous snakes.

**Flora.** Tennessee is noted for the abundance of its plant life and for the great variety of its species. In the Great Smoky Mountains alone are found 152 kinds of trees and more than 4,000 different types of plant life. In the Cumberland Mountains 40 types of plant life have been classified that are not known elsewhere in the world. Tennessee's flora form the transition between northern and southern botanical regions. In the mountains of east Tennessee are balsam fir, red and black spruce, sphagnum moss, climbing fumitory, and clintonia, characteristic of the vegetation of southeastern Canada. Rhododendron, iris, big laurel, holly, birch, mountain alder, blueberry, cranberry, and magnolia abound. In the marshy lowlands of west Tennessee are found bald cypress, salt reed grass, water elm, queen's root, hoary verrain, butterweed, cryngo, watershield, swamp white oak, and yellow water crowfoot.

Trees and plants also common to the state are pine, elm, beech, sycamore, basswood, wild cherry, black walnut, hickory, honey and black locust, maple, hackberry, sassafras, persimmon, willow, silverbell, yellow or tulip poplar (the State tree), pecan, tupelo, chinquapin, catalpa, redbud, dogwood, wild grape, pink wildbean, passion flower, trailing arbutus, woodbine, and poison ivy. Golden seal, hepatica, digitalis, and ginsing are among the best known medicinal plants.

About one half of the area of Tennessee—some 13,000,000 acres—is in forest land. In addition to the federally owned Cherokee National forest, there are a number of forests maintained by the state, and much of the area is under private ownership and management. In 1952, 50 of the state's counties were under the state Forestry Division's program of fire protection.

## ECONOMIC RESOURCES AND ACTIVITIES

**Mining and Minerals.** Some 55 minerals of economic importance are found in Tennessee. The bituminous coal fields of the Cumberland Mountains are among the most important. Clays of superior quality are found in limited quantities in the eastern section of the state and in great abundance in the western section. Substantial phosphate deposits occur in the south central section. Much marble is quarried in the eastern part of the state, and the Cumberland Plateau supplies sandstone in commercially important quantities. Zinc and copper are mined. In 1949, Tennessee produced 7,613,560 tons of stone, 4,500,000 tons of coal, 3,964,621 bbl. of cement, 4,056,000 tons of sand and gravel, 1,500,000 long tons of phosphate ore, 1,500,000 tons of zinc ore, and slightly more than 1,000,000 tons of copper ore. Sulphuric acid, a by-product of copper ore, was produced at the rate of 915,956 tons for the year. The total annual income from Tennessee's mineral operations averages $85,000,000.

**Fisheries.** The Tennessee Game and Fish Commission operates hatcheries at Erwin, Morristown, Flintville, and Springfield. They stocked the streams (and some smaller lakes) with large- and small-mouth bass, brook, rainbow, and brown trout, and bluegills. Commercial fishing, confined chiefly to the Mississippi River, Reelfoot Lake, and Tennessee-Kentucky Lake, is of minor importance. The catch consists of carp, catfish, buffalo fish, sunfish, and some crappie; mussel shells are gathered for use in the manufacture of buttons.

**Agriculture.** Farming in Tennessee is now highly diversified and as a result of rural electrification and modern equipment has become more and more productive. Annual cash receipts from crops average $660,000,000 and are growing. The cash value of some of the leading Tennessee crops in 1951 was as follows: cotton, $117,624,000, cotton lint, $103,140,000 and cotton seed, $14,484,000; corn, $105,630,000; tobacco, $66,898,000; hay, $49,708,000; soybeans, $8,485,000; wheat, $6,648,000; oats, $4,969,000; strawberries, $3,852,000; sweet potatoes, $2,871,000; Irish potatoes, $2,001,000; barley, $1,323,000; snap beans, $1,122,000; and lespedeza seed, $1,118,000. There are 1,016,204 persons living on 231,631 farms in the state; farms, buildings, livestock, and equipment in 1951 were valued at $2,300,000,000.

**Animal Industry.** In 1951, livestock was the greatest single source of farm income in Tennessee. The total value of livestock and poultry in the state as of Jan. 1, 1952, was $304,366,000. As of the same date, there were 1,658,000 cattle; 1,330,000 hogs, valued at $31,521,000; 274,000 sheep, valued at $7,343,000; 9,771,000 chickens; 126,000 horses, valued at $4,788,000; and 211,000 mules, valued at $10,550,000. The gross value of dairy products was $105,148,000 in 1951, and Tennessee ranked fifth in the nation in the production of cheese. The production of beef, pork, and mutton was valued at $185,000,000, that of poultry at $40,000,000.

**Horses.** The bluegrass region of middle Tennessee is famous for its horses. Most prominent is the Tennessee Walking Horse, developed from the old plantation horse and having a rolling, easy, "rocking-chair" gait. Thoroughbred, standardbred and American Saddle Bred horses are also raised in this section of the state. Interest in the thoroughbred has recently been revived, following a tradition of the early days of Tennessee, when Belle Meade Farm at Nashville, established in 1835, produced such great horses as Enquirer and Iroquois, the latter the only American horse to win the English Derby and the first thoroughbred to win the sum of $100,000. The Iroquois Memorial, a three-mile amateur race over 18 jumps, is held each May at Percy Warner Park in Nashville and is one of the fastest-run courses in America.

**Lumbering.** At present, Tennessee's rapidly growing forestry program, both state and private, is the basis of an industry with a $250,000,000 annual income. Tennessee is the world's largest producer of hardwood flooring; much of the rest of its lumber goes into furniture manufacture and industrial use.

**Power and Fuel.** Tennessee has an abundance of power and fuel. The T.V.A. supplies some 18 to 20 billion kilowatt hours of electric power annually; the state's coal reserves are estimated at 20,000,000,000 tons, and two natural-gas lines pass through the state and have distribution there.

Better than 85 per cent of Tennessee's farms and rural areas are now electrified, and many thousands of homes throughout the state are heated directly by electricity. Though much of the electric power that might be used by industry has been taken up by such installations as Oak Ridge, many new industries have been installed in Tennessee, particularly in the east, where T.V.A. power predominates. Industrial development of the state's western section is expected with the installation of steam power plants.

FAIRCHILD AERIAL SURVEYS—TENNESSEE CONSERVATION DEPT.

*AIR VIEW OF NASHVILLE, CAPITAL CITY OF TENNESSEE. THE STATE CAPITOL IS SHOWN IN THE INSET.*

**Manufacturing.** Manufacturing is Tennessee's greatest source of income. In 1951, the value added by manufacture was $1,200,000,000; 4,148 plants employed 257,700 persons.

Chemicals and allied products, textiles, and food and allied products are the principal manufacturing industries of the state. Others of prime importance include plastics, leather goods, printing and publishing, stone, clay, and glass products, appliances, and paper and allied products.

The greatest concentration of manufacturing concerns in Tennessee is in the eastern section of the state and around Memphis on the Mississippi River. Since World War II, however, Tennessee has seen the entry of manufacturing plants of various sizes into every section of the state. That section north and east of Knoxville, stretching to the Bristol-Kingsport area, is heavily industrialized. The area around Chattanooga also has many plants. From Memphis, the manufacturing area has spread north and east for as much as 75 or more miles. From Nashville, in middle Tennessee, industry has fanned out both north and south. In this section there are frequently one or two plants to a town, with workers enjoying rural living along with their industrial incomes.

**Banking.** As of June 30, 1952, there were 220 state banks in Tennessee having total assets of $643,017,221 and total deposits of $586,241,172; 74 national banks having total assets of $1,622,035,000 and total deposits of $1,507,405,000; and 3 non-Federal building and loan associations having assets of $2,348,952, private purchasable shares totaling $2,057,230, and deposits of $147,370.

**Tourist Trade.** The third largest industry in Tennessee is the tourist trade, with an estimated dollar volume in 1952 of better than $525,000,000. The state ranks among the top ten in the nation in this category and fourth in the nation in the sale of out-of-state fishing licenses.

The value of taxable property in the state in motels and motor courts alone is more than $80,000,000. More than 10,000,000 tourists visit the state each year.

**Communications.** There are 125 weekly or semiweekly newspapers published in Tennessee. The state also has 62 radio stations, and there are two television stations, one at Memphis and one at Nashville. Installations of telephones throughout the state, particularly in the growing urban centers, was reported in 1952 as up more than 100 per cent over 1946.

**Transportation.** As of June 30, 1952, there were 68,000 miles of roads in Tennessee, of which 15,000 miles were hard surface. The state spends $50,000,000 a year on its roads. Many bus and truck lines serve the state, as do 31 railroads. The principal railroads are the Louisville and Nashville, the Nashville, Chattanooga, and St. Louis, the Southern, the Tennessee Central, the Illinois Central, and the Gulf, Mobile, and Ohio. Railroad mileage in the state totaled 3,540. Tennessee has 55 public airports, of which

LEADING TENNESSEE INDUSTRIES
(1951)

| | *Persons Employed* | *Income from Payrolls and Profits ($1,000)* | *Value Added by Manufacture ($1,000)* |

EWING GALLOWAY

*Wilder Tower, in Chickamauga and Chattanooga National Military Park, was erected in memory of Wilder's Federal brigade on the site of Widow Glenn's cabin, headquarters of the Union commander, General W. S. Rosecrans, at the Battle of Chickamauga.*

30 are commercial and 25 municipal; 6 major air lines and 3 feeder air lines serve the state. The Mississippi, Tennessee, and Cumberland rivers provide 1,000 miles of navigable channel.

## GOVERNMENT AND POLITICS

**Structure of Government.** The state legislature, known as the General Assembly, is composed of a Senate and a House of Representatives, consisting respectively of thirty-three members and of ninety-nine members, all of whom serve terms of two years. The Assembly meets biennially on the first Monday in January of every odd year, and the legislators are paid for sessions lasting not more than seventy-five days; for any special session called by the governor they are paid for not more than twenty days. The governor is elected for two years; the secretary of state, the comptroller, and the treasurer are appointed by the legislature for terms of four years. There is a Supreme Court, consisting of five judges elected for eight-year terms, a Court of Appeals, and circuit courts, criminal courts, chancery courts, and inferior courts. In 1952 Frank Clement, Democrat, was elected governor of the state for 1953-1954.

**Legislation and Politics.** Except for abolishing slavery and setting up a judiciary, the present state constitution, drawn up in 1870, is substantially the same as the original document of 1796. Under it, all property must be taxed at the same rate, a provision which bars the adoption of a graduated income tax or the classification of property for taxation. Politically, Tennessee has voted Democratic in presidential elections since the War Between the States except in 1920, 1928, and 1952. In 1953 the state's two senators in Congress were Estes Kefauver and Albert Gore, both Democrats; by the Congressional reapportionment based on the census of 1950, the state's membership in the United States House of Representatives was reduced from ten to nine, effective in the 1952 elections.

**State Finance.** On Jan. 1, 1950, Tennessee ceased to levy a state property tax on real estate, personal property, or mixed real and personal property. Counties, cities, and towns levy a general property tax at varying rates, determined annually in view of their budgets. Railroad and public utilities properties are assessed by the Tennessee Railroad and Public Utilities Commission and are taxed at the rates established by local governments for other kinds of property.

Tennessee levies no graduated individual income tax, but its constitution does authorize a tax levied on income derived from stocks and bonds. The state levies a retail sales tax of 2 per cent and a tax on certain rentals of personal property.

As of July 1, 1944, Tennessee put into effect an amendment to the state payroll tax which is considered a model. Under this amendment, the tax rate for each employer of 8 or more persons who has been taxable for 36 months is made dependent on two considerations: first, upon the employer's experience with unemployment and second, upon the amount in the state's reserve fund for compensating unemployment. This experience-rating plan has saved Tennessee employers $81,000,000 in its first eight years.

General revenue for Tennessee for the fiscal year ending June 30, 1952, totaled $242,000,000. Taxes, licenses, and fees amounted to $180,700,000; Federal aid, $46,600,000; and miscellaneous collection, $10,500,000. Bond sales brought $5,000,000. Of these collections, the sales tax, totaling $50,000,000, and gasoline and motor fuel taxes, totaling $49,600,000, were the largest single sources of revenue. Expenditures for the year totaled just over $245,000,000; $70,800,000 were spent on educational services, and $54,600,000 on highways. The state debt was reduced in the year from $100,200,000 to $97,400,000. The state treasury reported an accumulated surplus of $17,560,267 in the general fund.

## SOCIAL AND CULTURAL ACTIVITIES

**Education.** In Tennessee, education is compulsory for children from the ages of seven to sixteen, or until completion of the eighth grade. In the scholastic year ending June 1951, enrollment in the first twelve grades in the public schools totaled 675,634. There were 4,432 public schools in the state. Segregation is prescribed by law, white and Negro pupils being taught in separate institutions. The average monthly salary for all teachers in public schools, both city and county, was $222.27.

State colleges include the University of Tennessee at Knoxville, Memphis, and Martin; Memphis State College, at Memphis; the Middle Tennessee State College, at Murfreesboro; the East Tennessee Polytechnic Institute, at Cookeville; the Austin Peay State College, at Clarksville; East Tennessee State College, at Johnson City; Tennessee State Agricultural and Industrial University, for Negroes, at Nashville; and the Alvin C. York Agricultural Institute, at Jamestown. Private institutions of higher learning in the state include the University of Chattanooga; Fisk University and Meharry Medical College, for Negroes, at Nashville; Cumberland University, at Lebanon; the University of the South, at Sewanee; Maryville College, at Maryville; Southwestern University, at Memphis; and Scarritt College, Vanderbilt University, George Peabody College for Teachers, and Belmont College, all at Nashville.

Special education is provided for physically handicapped and crippled children; for the deaf and hard-of-hearing; for children of school age who are blind or partially sighted; and for children having defective speech.

**Social Services.** In October 1952, 59,792 recipients of old-age assistance in Tennessee received an average of $36.81 in payments; 59,649 dependent children in 19,693 families received an average family payment of $49.45; and 2,870 recipients of aid to the blind received an average payment of $41.78.

As of Jan. 1, 1952, 9,428 beds were available for mental patients in Tennessee; there were 11,279 beds in general hospitals, 2,441 beds in tuberculosis hospitals, and 3,128 beds in hospitals for chronic diseases.

**Cultural Activities.** There are extensive library facilities in Tennessee, including the Joint Universities Library, supported by Vanderbilt, Peabody, and Scarritt at Nashville. Numerous bookmobiles travel throughout the state. There are several symphony orchestras, notably those at Nashville and Oak Ridge. Several art museums are maintained, offering both permanent and traveling exhibits; the Children's Museum at Nashville is one of the few of this nature in the country, and the Tennessee Historical Society and the Association for the Preservation of Tennessee Antiquities are both active.

## POPULATION

According to the United States Census of 1950, the population of Tennessee was 3,291,718, ranking it sixteenth among the states. This represented an increase of 12.9 per cent over 1940. Figures of the Tennessee State Planning Commission as of September 1952 show that 1,016,204 persons—30.9 per cent—constituted the state's farm population, the remainder living in urban places. Tennessee has a native-born population of 99.49 per cent. Of this, 80.23 per cent is white, 19.26 per cent Negro.

Persons employed in the state in September 1952 totaled 1,093,300. These include approximately 290,000 in agriculture; 276,700 in manufacturing; 180,400 in wholesale and retail trade; 120,100 in state, Federal, and local government; 76,400 in services; 61,700 in transportation and communications; 52,700 in construction; 24,700 in finance, insurance, and real estate; and 10,600 in mining.

## FAMOUS SITES AND PLACES

Tennessee has numerous points of interest, historic, natural, and man-made. The many T.V.A. lakes and United States Engineers lakes offer not only scenes of surpassing beauty, but excellent fishing as well.

Reelfoot Lake, formed by an earthquake in 1811, lies in the northwestern corner of Tennessee; Memphis, the largest city of the state and the largest cotton and hardwood center of the world, has a number of historic points of interest and is the scene of the Annual Cotton Carnival; Shiloh National Military Park, near Savannah, Fort Donelson National Military Park, with the best-preserved breastwork of the War Between the States, and Nathan Bedford Forrest Memorial Park all lie in the western section of the state. In middle Tennessee, the largest blue-grass region in the world, there are a number of natural bridges near Waynesboro; the Meriwether Lewis National Monument; the home of James K. Polk, eleventh president of the United States, at Columbia; Jewell and Dunbar caves; the State Capitol, the Parthenon, Fort Nashborough, the Children's Museum, and The Hermitage, home of Andrew Jackson, all in or near Nashville; the Sam Davis Memorial Home, near Smyrna; and Stones River National Military Park near Murfreesboro.

In the Cumberlands, said to be the world's oldest mountains, are Wonder Cave; historic Monteagle; Rugby, a town established in 1877 by Thomas Hughes, author of *Tom Brown's Schooldays;* and Fall Creek Falls, the highest waterfall in the eastern United States.

Chattanooga has many points of historic and scenic interest. Lookout Mountain, Signal Mountain, and Missionary Ridge all were sites of battles in the War Between the States; Chickamauga and Chattanooga National Military Park is nearby.

Montlake, a geologic phenomenon, is near Daisy; Knoxville is the site of the Blount Mansion, the home of William Blount, and the grave of John Sevier, the first governor of the state. Nickajack Cave and Indian Cave are in east Tennessee. At Oak Ridge there is the American Museum of Atomic Energy.

The Andrew Johnson National Monument and the original tailor shop of the seventeenth president of the United States are at Greeneville. Roan Mountain, high in the Cherokee National Forest, has its annual rhododendron festival, with 600 acres of the beautiful plant in bloom at one time. Erwin is the scene of the annual historical pageant, *Overmountain Men.*

The Great Smoky Mountains National Park and its headquarters town of Gatlinburg draw more visitors each year than any other national park. Tennessee has 17 state parks spread throughout the state, the majority offering vacation facilities, including furnished cottages or hotels. An excellent system of historical markers covers the roads and highways of the state.

Cumberland Gap National Historical Park, on the Tennessee-Virginia-Kentucky border, was scheduled to be dedicated in 1953.

Hunting regulations in Tennessee vary from year to year. There is no closed season on fishing, except for trout. In 1952, out-of-state fishermen could obtain a three-day nonresident fishing permit for $1.00.

## HISTORY

Hernando de Soto, the Spanish explorer who discovered the Mississippi in 1541, presumably stood on present-day Tennessee soil at or near Memphis. No Spanish occupation followed, however, and more than a century later England and France became rival claimants to the region. In 1673 two Virginia traders visited the Indians in the southeastern part of Tennessee, and in the same year Marquette and Joliet landed briefly at the western end of the state. La Salle built Fort Prudhomme at the mouth of the Big Hatchie River in 1682. For the next one hundred years the French and the British, as rivals, attempted to control the Indians and to assert their territorial rights.

In the decade preceding the American Revolution many settlers, stimulated by the glowing tales of hunters and land agents, began to move into Tennessee from Virginia and the Carolinas. They settled along the Watauga, Nolichucky, and Holston rivers in the eastern end of the state and soon set up a completely independent government of their own, which they called the Watauga Association. Several years later the settlers organized the District of Washington, the first local division of government to be named after George Washington. In 1777 the district was annexed to North Carolina, and when that state ceded its western lands to the United States in 1784 the eastern settlers organized the State of Franklin, which maintained a precarious existence for the next four years. North Carolina, having re-established jurisdiction over the area in 1788, and again in 1789, ceded it to the newly established Federal Government. In 1790 the region was organized as the "Territory South of the Ohio River," William Blount becoming its governor. The serious problems of land speculation and settlement, Indian warfare, and Spanish intrigues characterized these formative years.

On June 1, 1796, Tennessee was admitted to the Federal Union as the sixteenth state, with John Sevier as governor. The state was still in the pioneer stage of development. The original state constitution, adopted in 1796, was

revised in 1835 and again in 1870. As a result of a public referendum in 1952, a constitutional convention took place in April 1953 to consider revision of certain specific portions of the constitution. This was the first successful attempt to hold a state constitutional convention since 1870. The capital of the state was finally established at Nashville in 1843; the Great Seal of the state was first used in 1802. During the War of 1812 Tennessee furnished soldiers in excess of its quota and was the scene of much Indian fighting. During the next half century the state showed great progress in canal and road building and in state banking ventures. It was the home of three presidents: Andrew Jackson, James Knox Polk, and Andrew Johnson, and of two presidential candidates: Hugh L. White and John Bell.

Tennessee was the last state to secede from the Union during the War Between the States and the first to return after hostilities ceased. Efforts to bring about secession after the election of Abraham Lincoln were unsuccessful until Fort Sumter was fired on. In June 1861, the people of the state voted to secede by a declaration of independence rather than an actual act of secession. The state was represented in both the United States Congress and the Confederate Congress during the first year of the war, largely because so many east Tennesseans remained loyal to the Union. For the next four years Tennessee was the scene of much bloody and bitter fighting, 454 recorded battles and skirmishes being fought within its borders. The first pitched battle in the West, at Shiloh, Apr. 6-7, 1862, and the last of importance, at Nashville, Dec. 15-16, 1864, took place on Tennessee soil. Forts Henry and Donelson were captured in February 1862, and Nashville was then occupied by Union troops. Andrew Johnson was appointed military governor of the state by Lincoln. Important fighting in Tennessee took place at Murfreesboro, or Stones River, at Knoxville and Chattanooga, at Chickamauga, on the southeastern border, and, in the final western campaign, at Franklin. Tennessee was exempted from the provisions of the Emancipation Proclamation, but abolition of slavery was provided for in a constitutional amendment adopted in February 1865. At that time a Radical state government, headed by William G. Brownlow as Governor, replaced the military government, and on July 24, 1866, Tennessee was readmitted to the Union.

As a result of sectionalism and of Radical control of the governments of the southern states, the Ku Klux Klan was organized in Pulaski in 1866. The organization soon spread throughout the south, and despite its disbandment by its original organizers in 1871, terrorist groups used its name for many years. Radical rule came to an end, and Democratic control of the state was restored in 1870. During the next half century, Tennessee slowly developed its natural resources and industries, though it remained predominantly agricultural for many years. Later, many important textile, chemical, and plastic manufacturing plants became established in the state. One of the largest book manufacturing concerns in the world is located at Kingsport, and coal mining and aluminum production are important industries. Industrial growth and agricultural expansion were extended by the establishment in 1933 of the Tennessee Valley Authority, with headquarters in Knoxville. The T.V.A. won public support as a base of cheap electric power derived from hydroelectric installations in the drainage basin of the Tennessee River. Availability of this power for industry and the attractions of the man-made lakes to tourists were seized upon by Tennesseans, who have developed them in the interests of private enterprise.

At Oak Ridge, north of Knoxville, the first atom bomb was assembled, the laboratories for its manufacture being placed in the area largely because it was both remote and at the same time near transportation and cheap electric power.

State-wide prohibition was enacted in 1909 but was modified by a local-option law permitting package sales beginning in 1939; a workmen's compensation bill became effective in 1919, and the convict-lease law was repealed in 1936. In 1949, the state legislature abolished the poll tax as a prerequisite for voting in primary elections for all state and national offices and exempted women, veterans, and the blind from this requirement in all elections. Permanent registration for the state's voters was established in 1951. Sgt. Alvin C. York, of Pall Mall, Fentress Co., and the Hickory Division became world-famous in World War I, during which Tennessee contributed nearly 100,000 men to the armed forces. During World War II the state contributed 241,000 men and 2,442 women to the army, and 44,047 men and 1,073 women to the navy. T. R. H. and T.S.

**TENNESSEE, UNIVERSITY OF,** an accredited, coeducational, state-controlled institution. The main campus is at Knoxville, Tenn., but the colleges of Medicine and Dentistry, the Graduate School of Biological Sciences, the schools of Pharmacy and Nursing, and the Division of Public Health are all located at Memphis. The University of Tennessee Junior College is located at Martin, and substations of the Agricultural Experiment Station are located at Jackson, Columbia, Clarksville, Crossville, Greeneville, and Springfield. Tennessee University occupies a total area approximating 4,500 acres. It was originally established in 1745 as Blount College. In 1807 it became East Tennessee College, and in 1840 it became East Tennessee University. The school was incorporated as the Agricultural and Mechanical College in 1869, and ten years later it became the University of Tennessee.

The divisions of the university include agriculture, liberal arts, home economics, engineering, education, law, business administration, graduate school, medicine, dentistry, pharmacy, nursing, public health, and biological sciences. These divisions offer the following degrees: the A.B.; the B.S. in chemistry, business administration, education, home economics, pharmacy, agriculture, and chemical, civil, electrical, mechanical, agricultural, and physical engineering; the LL.B.; the M.D.; the D.D.S.; the M.S.; the M.A.; and the Ph.D. A branch of the Graduate School has recently been opened at Oak Ridge as part of the Nuclear Studies Institute.

Chapters of many fraternities and sororities have been established on the campus and male students are permitted to live in the fraternity houses. Dormitories and dining facilities have been provided for both men and women. Scholarship assistance is generous and a loan fund has been established. *For statistics see* COLLEGES AND UNIVERSITIES.

J. R. To.

**TENNESSEE AGRICULTURAL AND INDUSTRIAL STATE UNIVERSITY,** an accredited, coeducational, state-controlled institution for Negroes. It is primarily an institution for teacher training and is a land-grant college which occupies 470 acres in Nashville, Tenn. The school was originally established in 1909 by the Tennessee general assembly and at that time was called the Agricultural and Industrial State Normal School. In 1922 the privilege of granting degrees was received, and during the following year the present name was adopted. In 1951 the institution was reorganized into the four schools of Engineering, Arts and Sciences, Education, and Graduate Studies

The degrees offered include the A.B. in liberal arts, the B.S. in business administration and engineering, the M.S., and the M.A.

Chapters of several sororities and fraternities have been established on the campus. Dormitory facilities are available but most of the students commute. Scholarship assistance is limited. *For statistics see* COLLEGES AND UNIVERSITIES.

J. R. To.

**TENNESSEE POLYTECHNIC INSTITUTE,** an accredited, coeducational, state-controlled, technological institution. It occupies a 221-acre campus in Cookeville, Tenn. The school was originally chartered as a junior college in 1915, but in 1928 it was reorganized as a senior college and received the power to grant degrees. The degrees offered are the B.S. in liberal arts, business administration, engineering curricula, agriculture, and home economics. Dormitories are available for both men and women, but most of the students commute. There are no national sororities or fraternities on the campus. There are no scholarships offered and only a small fund is available for student loans. *For statistics see* COLLEGE AND UNIVERSITIES. J. R. To.

**TENNESSEE RIVER,** 652 mi. long, the largest tributary of the Ohio River. The headwater streams of the Tennessee River are the French Broad and Holston rivers, which join 4 mi. north of Knoxville, eastern Tennessee, to form the Tennessee River. The river flows generally southward through the Great Appalachian Valley to Chattanooga, where it turns north from Lookout Mountain to Walden Ridge. It then flows southwest into northern Alabama, where it bends to the northeast at Guntersville Dam and again flows into Tennessee. The river then bends to the north as it crosses western Tennessee and southwestern Kentucky to enter the Ohio River at Paducah, Ky. The Tennessee River is noted for being unusually free from sediment and having a steady flow of water. The Muscle Shoals Navigation Power Dam, part of the Tennessee Valley Authority, is located on the river near Florence, Ala. The major tributaries are the Duck, Clinch, Hiwassee, Sequatchie, Big Sandy, and Little Tennessee rivers, and Bear Creek; the whole system drains an area of about 40,569 sq. mi. The Tennessee is important as a source of the power which has developed and influenced the whole Southern economy. The most important cities on or near the Tennessee River are Paducah, Ky.; Savannah, Chattanooga, and Knoxville, Tenn.; and Florence and Decatur, Ala. J. E. F.

**TENNESSEE STATE COLLEGE, EAST,** an accredited, coeducational, state-controlled institution, primarily for teacher training. The school occupies a 162-acre campus in Johnson City, Tenn. It was originally established in 1909 as the East Tennessee State Normal School. The power to grant degrees was received in 1925 and the name was changed to East Tennessee State Teachers College. The present name was adopted in 1943. The B.S. is the only degree awarded. Dormitories and dining halls have been established for both men and women. There are no national fraternities or sororities on the campus. No scholarships are offered, but a substantial fund has been established for loans to students. *For statistics see* COLLEGES AND UNIVERSITIES.

J. R. To.

**TENNESSEE STATE COLLEGE, MIDDLE,** an accredited, coeducational, state-controlled institution for the training of teachers. The college occupies about 375 acres in Murfreesboro, Tenn. The school was originally established in 1909 as a normal college and students were first admitted two years later. In 1925 the power to grant degrees was received and the name was changed to State Teachers College. The present name was adopted in 1943. The only degree offered is the B.S. in education, with some majors in business and liberal arts. Dormitories and dining halls are provided for both men and women, and living quarters are made available to married veterans. There are no national fraternities or sororities on the campus, and, as no provision has been made for scholarship and student loans, many of the students earn all or part of their expenses. *For statistics see* COLLEGES AND UNIVERSITIES. J. R. To.

**TENNESSEE VALLEY AUTHORITY.** In the first years of the twentieth century private enterprise had become interested in the possibilities for hydroelectric power development at Muscle Shoals on the Tennessee River in northern Alabama. No action was then taken, but alert members of Congress were awakened to the possibilities of combining power development with river navigation improvements, all under public control.

Participation of the United States in World War I caused President Woodrow Wilson to approve the building of a nitrate plant at the site, and construction was started at the present sites of the Wilson Dam and the Wheeler Dam, both at Muscle Shoals on the Tennessee River in northern Alabama. Before the plants were completed the war ended, and the Government planned to lease the nitrate plants to private enterprise. Various proposals were received, but Congressional delay, and the introduction of bills providing for the establishment of a government corporation to control and operate the Muscle Shoals properties, postponed any final action. In the meantime the Wilson Dam and powerhouse had been completed and the electric power generated was sold on various contracts from 1925 to 1934 to the Alabama Power Company.

In his first inaugural address, President Roosevelt, recognizing that conditions existing in the river's watershed presented an opportunity for economic and social experimentation, asked for legislation to end "the continued idleness" of the Muscle Shoals development and "to enlist this project in the service of the people." He proposed legislation "to create a Tennessee Valley Authority—a corporation clothed with the power of Government, but possessed of the flexibility and initiative of a private enterprise." On May 18, 1933, the President approved an act of Congress establishing the Tennessee Valley Authority (T.V.A.). The revenues to be derived from the sale of the hydroelectric power, a by-product of flood control and conservation, were expected, eventually, to make the T.V.A. self-sustaining from an economic viewpoint, while at the same time raising the level of social welfare and economy in the area. Flood control, the production of cheap electricity for power and lighting purposes, the manufacture of large quantities of fertilizer for agricultural purposes, the institution of soil conservation programs and of better farming methods, as well as other benefits, have resulted. The first board chosen to carry out the program had Arthur E. Morgan, a distinguished engineer who was then president of Antioch College at Yellow Springs, Ohio, as chairman, with Harcourt A. Morgan (no relation), president of the University of Tennessee, and David E. Lilienthal of the Wisconsin Public Service Commission as the other two directors, appointed respectively for nine, six and three years.

The T.V.A. had hardly got under way before it was subjected to court action on the grounds of unconstitutional government interference with private competing interests.

Constitutionality of the T.V.A. act, though only in an indirect form, was finally established by the United States Supreme Court in *Tennessee Electric Power Company* v. *Tennessee Valley Authority* in 1939. This case was the culmination of prolonged litigation challenging the legality of contracts entered into by T.V.A. with municipalities. Furthermore, while the constitutional question was being debated in the courts, a controversy raged among the directing personnel on questions of administration. The controversy was resolved when the President removed Arthur E. Morgan from office and later made Lilienthal chairman.

In the midst of the controversy within the board of directors of the T.V.A., the opposition from privately owned public utilities in the area reached a climax. The Commonwealth & Southern Corporation, headed by Wendell Willkie, had, for six years, been engaged in an effort to prevent public ownership of electric utilities in the T.V.A. area. Private investors were reluctant to invest in the securities of corporations that might be taken over by T.V.A. through court action at condemnation proceedings. To make his claim more effective and to publicize his problem, Willkie went to the White House and presented such a clear statement of his case that what could be considered a fair price was paid for the Commonwealth & Southern property.

In connection with this controversy, one of the Government proposals was that T.V.A. rates for electricity be used as a "yardstick" for measuring the fairness of utility rates in contiguous T.V.A. territory and, in fact, throughout the country as a whole. This proposal was rejected by the privately owned utilities, which contended that such comparisons were unfair. T.V.A. paid no taxes, it was able to secure funds, as required, at lower interest rates than could be obtained by private utilities. Operating deficits were made up from public taxes in the form of deficiency appropriations. T.V.A., it was charged, had other advantages, not the least of which was the fact that it was a government corporation. In addition, it was contended that conditions were not the same in all parts of the country. None of these objections, however, prevented the T.V.A., after the United States Supreme Court had indirectly given its approval in 1939, from proceeding to carry out its authorized program in the Tennessee Valley.

Another potential handicap that T.V.A. has had to surmount or evade was that of political interference both with its operation and with its personnel. The United States Senators from Tennessee were insistent that the appointment of employees of the Authority be turned over to Congress so that the Senators could designate and control the appointments. Numerous amendments to this effect were attached to important bills in Congress, but they were defeated. Congress, however, did make a concession to the recalcitrant senators by withdrawing the blank check appropriation method and substituting requirements for detailed accounting of expenditures. The T.V.A. has been criticized for failing to pay its own way. Its profits have been characterized as illusory and misleading. In spite of subsidies, the T.V.A. has paid only a token interest on its investment and none into a sinking fund. The American tax-payer has paid most of the interest. But the claim is made by its proponents that the T.V.A. should not be considered from the sole viewpoint of earning power, but rather from that of over-all benefit to the locality, the state, and the nation; that the T.V.A. created values where none had previously existed; and that it has enhanced the value and worth of the territory in which it operates, either directly on the land or through the sale and re-sale of large quantities of cheap electricity which brought businesses into the region and thus gave employment where no such opportunity had previously existed.

Again, because its functions represented a new relationship between government, the local community, and private industry, the T.V.A. aroused both local and national praise and opposition. Its critics characterized the project as an experiment in socialization and regimentation, in which the local citizens and industries would be ruled and directed by a government corporation financed by tax-payers' money. Advocates and supporters of the undertaking insisted that unorganized and aimless use of the natural resources of the region had destroyed much of their value and that no organized efforts were being made to conserve, restore or replace these resources; that no attention was given to the social welfare of the people of the region; that planning, when done at all, was haphazard, unrelated and inadequate; and that available natural resources, especially power in various forms to be derived from the harnessing of the waters of the Tennessee Valley, would provide the funds and the means of overcoming the handicaps imposed on the region by haphazard methods and exploitation.

To a varying degree the T.V.A. has accomplished the purposes for which it was created. It has constructed a system of flood control that has been effective; it has produced and sold electricity in such quantities as nearly to finance the costs of the various projects; it has immensely improved the social, economic and living conditions in the area; it has greatly increased the use of inland waterways in the area; it has introduced reforestation and soil conservation measures that have increased the productivity of the region; it has produced a quantity and variety of fertilizers that have been of great value in increasing land productivity wherever they have been used; and during World War II the T.V.A. proved to be an asset of great value because of its ability to provide large volumes of electric power for national defense, particularly in connection with the atomic energy program carried on at Oak Ridge. All of these benefits have not been confined to the T.V.A. area. Many of the products produced in the territory have gone elsewhere. The practical problems worked out have served as models for other parts of the country, and the increased population and purchasing power have provided profitable markets for goods produced outside the area.

T. R. H.

**TENNIEL, SIR JOHN** [tɛ'nyəl] (1820-1914), English painter and illustrator, was born Feb. 28, 1820, in London. He was a student at the schools of the Royal Academy, where his later work was exhibited. In 1850 he joined the staff of the humorous magazine, *Punch,* to which he contributed a weekly political cartoon. As a painter, he carried out a commission for a fresco in the Parliament buildings, depicting St. Cecily (1846). He was also a member of the Royal Institute of Painters in Water Colours, and his water colors have found places in many museums. Tenniel is well known as the illustrator of Aesop's *Fables* (1848) and Lewis Carroll's *Alice's Adventures in Wonderland* (1865) and *Through the Looking Glass* (1872). He died in London, Feb. 25, 1914.

C. P. P.

**TENNIS.** The game of tennis, or lawn tennis as it is more properly called, is of comparatively modern development. Its history dates from December 1873, when Major Walter Clopton Wingfield introduced the sport to his guests at a garden party on his estate at Nantclwyd, Wales. It was his adaptation of the ancient game of kings, court tennis, which has a history of seven hundred years. In 1874 Major

Wingfield, an officer in the British Army, patented the game under the Greek name of Sphairistike. The court on which it was played was in the shape of an hourglass, measuring 60 ft. long, 30 ft. wide at the base lines, and 21 ft. wide at the center, where a net was suspended. The net was 7 ft. high at the ends and sagged to 4 ft. 8 in. at the middle. Sphairistike was introduced into the United States in the spring of 1874 by Miss Mary Ewing Outerbridge, whose brother, A. Emilius Outerbridge, received permission for her to set up her net and mark out the hourglass-shaped court on the grounds of the Staten Island Cricket and Baseball Club at St. George, Staten Island. Newport and Philadelphia became early centers of tennis, along with New York and Boston. The first important tournament was at Staten Island in 1880.

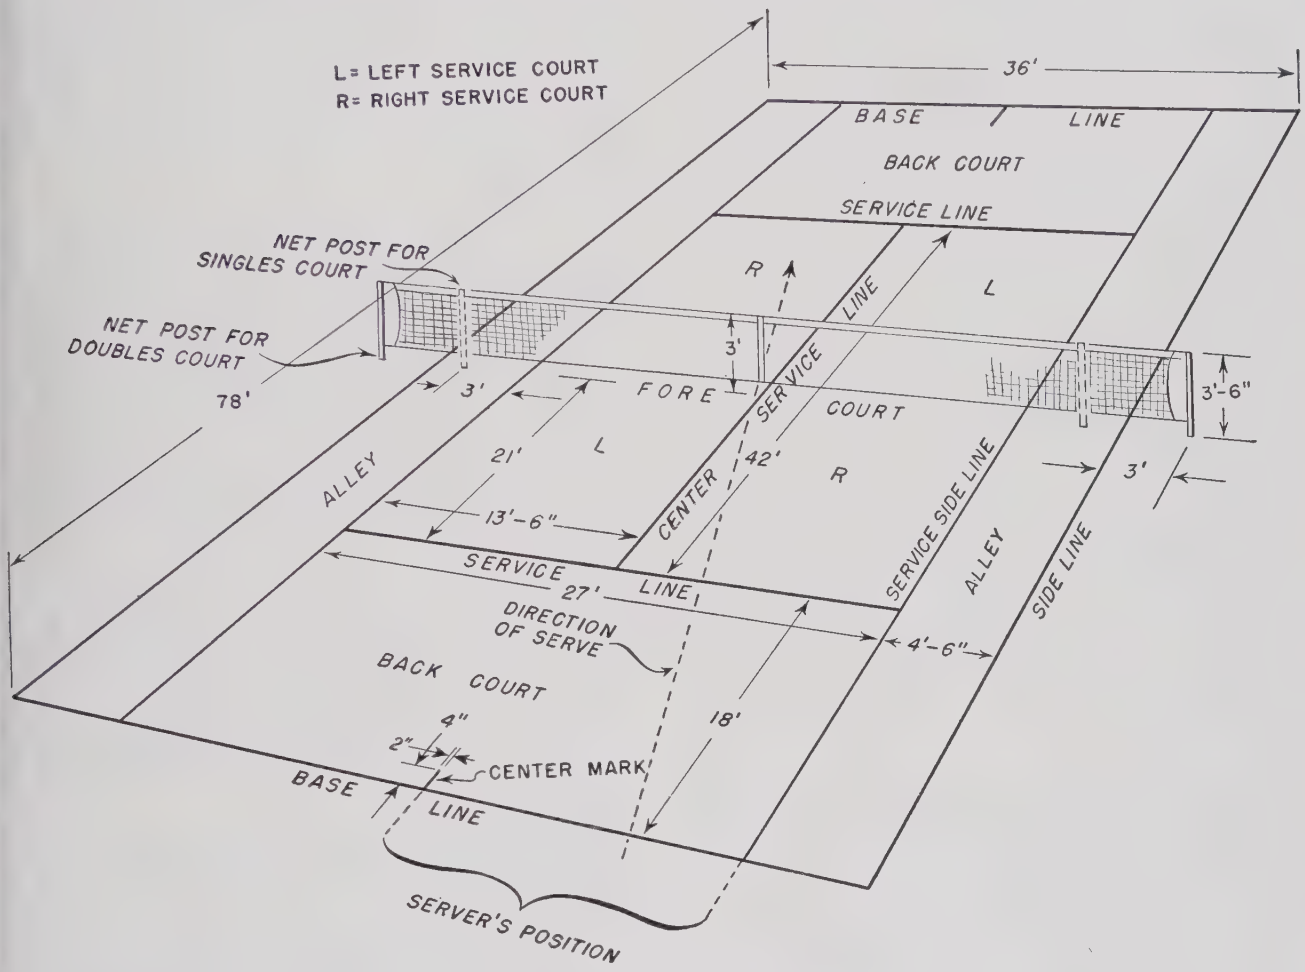

DIAGRAM OF A TENNIS COURT

## LAWN TENNIS

Confusion and controversies over varying sizes of balls, differences in the height of the net, and the playing rules led to a demand for standardization of the rules, regulations, and playing equipment. A meeting was held in New York on May 21, 1881, at which the United States National Lawn Tennis Association was organized. The national championship was started at that time.

**Court and Equipment.** Tennis is played on a rectangular court of varying surfaces. The surface most used in the United States is clay. Other surfaces are grass, cement, asphalt, patented compositions, concrete, and wood. The fastest outdoor surface is grass, and it is on grass that the most important championships are held in the United States, England, and Australia. In the countries of Europe, fast-drying, composition surfaces are the rule.

The court measures 78 ft. in length and 27 ft. in width for singles. For doubles, in which there are two players on each side, the width is 36 ft. Most courts are laid out for doubles, with inner boundaries marked for singles. The court is divided into two equal parts by the net which is suspended from a cord or metal cable, each end of which passes over the top of a post, 3 ft. 6 in. in height and standing 3 ft. outside the court on each side. The height of the net at the center is 3 ft. The boundary lines of the court are known as base lines and side lines. On each side of the net, 21 ft. from it and parallel with it, is drawn the service line, extending from side line to side line. The center service line, 2 in. wide, divides the space from the net to the service line on both sides of the court into service courts. Each base line is bisected at the center by a line 2 in. wide and extending 4 in. into the court, known as the center mark.

The ball is a hollow rubber sphere, inflated to a high pressure, with an outer surface of tightly drawn flannel. It must measure between $2\frac{1}{2}$ in. and $2\frac{5}{8}$ in. in diameter, and weigh between 2 oz. and $2\frac{1}{16}$ oz. There is no official restriction on racket size or material, but most rackets are made of laminated wood, are strung with gut or nylon, weigh less than 1 lb., and are about 27 in. long and 9 in. wide.

**Method of Play.** The game of singles is played with one player to a side, doubles with two. Service alternates with each game, and courts are exchanged after every odd-numbered game in each set. The first service in a game is delivered from any point behind the baseline between the center mark and the right sideline; thereafter, the service alternates from right to left of the center mark with each point of the game. The ball is always delivered to the service court diagonally opposite on the far side of the net. The server tosses the ball into the air and hits it with the racket before the ball hits the ground. In doing this he must not walk or run, must maintain contact with the ground, and must keep both feet behind the baseline, until the racket strikes the ball. Failure to observe these requirements results in a "foot fault," and the service is judged not good. To be a fair service, assuming no foot fault is called, the ball must touch within the boundaries of the proper service court without touching the net. If it tips the net before landing fairly, a "let" is called, and the service is repeated. If the ball does not land in the proper service court, a "fault" is called and the service is judged not good. If the first service is a fault, a second service is allowed. A let is not counted as a service. Two service faults in succession are called "double fault" and count as a point for the receiving player.

The receiver usually stations himself near the baseline, about halfway between the center mark and the sideline. He may not play the service until it strikes in his service court. He then attempts to return it to any part of the opposite court. In turn, the server attempts to return the ball, and a "rally" ensues, ending when one player commits an "error" or scores a "placement." An error is made when the ball is driven into the net or beyond the boundary lines; a placement is made when the ball is so directed that the opposing player is unable to reach it and make a return. Except on the service, a ball tipping the net before landing in the proper court is good; except on the service, the ball may be hit before it bounces and must on all occasions be hit before it bounces twice.

*Scoring.* A player making a service ace (a service that the receiver is unable to return successfully) or a placement, or whose opponent commits a double fault or an error, wins the point. The first point for each player in a game is called "fifteen," the second "thirty," the third "forty," and the fourth "game." No points is "love." A forty-forty score is called "deuce," and it is then necessary for one player to win two successive points before game is reached. The point won after deuce is called "advantage"; it is "advantage in" if the server is ahead, "advantage out" if the receiver leads. If the player gaining advantage loses the next point, the score reverts to deuce. The player first winning six games wins a "set," except that when each has five games, one must then win two games in succession to take the set. Matches are decided by the best of three sets, or the best of five.

*Doubles.* Doubles play is similar to singles. The two members of each team move about the court as they please (except the server in the act of serving); they are not required to hit the ball alternately, as in some other racket games. They take turns serving, each serving a complete game every other time it is the team's turn to serve. Scoring is the same as in singles.

**Championships and Players.** Richard D. Sears won the first seven United States singles championships, a record run never since equalled. William A. Larned later won seven titles, five in succession, and after World War I William T. Tilden II, said to be the greatest player of all time, also won seven titles, six in succession. Maurice E. McLoughlin helped to popularize tennis before World War I with his extremely fast "cannonball" service. William Johnston won the singles title twice and reached the finals six other times. After Tilden, only Ellsworth Vines, Donald Budge, and Jack Kramer rose to comparative dominance over American tennis.

The earliest successful foreign players in American tennis were Reginald and Hugh Doherty of Great Britain in the early 1900's. Norman Brookes and Anthony Wilding of Australia played fine tennis in the United States before World War I. In the late 1920's France's Rene Lacoste, Henri Cochet, Jean Borotra, and Jacques Brugnon ruled American and world tennis. In the early 1930's Fred Perry of Great Britain and Jack Crawford of Australia were outstanding; later Baron Gottfried von Cramm of Germany and John Bromwich of Australia made strong showings. Frank Sedgman and other Australian stars dominated tennis in the early 1950's.

*Women.* May Sutton, who won both American and British championships, was the first great American woman tennis player. She was followed by Hazel V. Hotchkiss and Mary K. Browne. Molla Bjurstedt won eight singles titles during and following World War I. Helen Wills, ranked with Suzanne Lenglen of France as the greatest of all women tennis players, won seven American and eight British singles titles. From 1932 until World War II, Helen Jacobs, Alice Marble, and Sarah Palfrey dominated American singles and doubles championships. Pauline Betz, Louise Brough, and Margaret Osborne were outstanding in the 1940's, the latter two winning the national doubles title nine years in succession. Maureen Connolly rose to rule women's tennis in the early 1950's.

*International.* Various countries compete annually for the Davis Cup, a trophy put up in 1900 by an American, Dwight F. Davis. Although many countries have entered Davis Cup play, only four have ever won the cup; the United States, Australia, Great Britain, and France. British and American women's teams have played annually since 1923, except during World War II, for the Wightman Cup, donated by Mrs. George W. Wightman, the former Hazel V. Hotchkiss.

*Professional.* Professional tennis began in earnest in 1926 when Suzanne Lenglen, Mary K. Browne, Vincent Richards, and others went on an exhibition tour. William T. Tilden turned professional in 1930, to be followed later in the 1930's by Ellsworth Vines, Fred Perry, Don Budge, and others. Robert L. Riggs, former singles champion, tried to revivify professional tennis after World War II, but although he persuaded Jack Kramer and other great stars, both men and women, to join him, professional tennis did not meet with conspicuous success.

## COURT TENNIS

Court tennis, the game from which lawn tennis is derived, is over seven hundred years old and at one time was played by the monarchs of continental Europe and England. Highly popular with the masses from the fourteenth to the nineteenth century, by the middle of the twentieth century it had a very small following, limited to membership in a few exclusive clubs in England, France, and the United States. Its introduction into the United States occurred in 1876, when a private court was built in Boston.

**The Court.** Court tennis is played in an indoor court measuring 110 ft. by 38 ft., with a skylight 30 ft. overhead. The four walls and the floor are made of cement. Some of the modern courts, with their dressing rooms, baths, showers, and other appurtenances, have cost as much as $250,000.

Among the features of the court are a roofed shed, running around three sides of the court, and the tambour. The shed is called the penthouse. The tambour is a projection of one of the long walls on the hazard side. The other side of the court is known as the service side.

**Method of Play.** As in lawn tennis, a racket and a flannel-covered ball are used. A net divides the court at the middle, and the scoring is similar to that of lawn tennis. But there are important variations. The play is not only over the net but also against the walls. There are numerous openings in the walls, and when the ball is directed into the dedans (gallery at service end of court), grille, and winning gallery, a point counting fifteen is scored. Certain wall openings mark "chases," and there are chase lines on the floor. The chase is a stroke whereby the ball, untouched by the receiving player, enters any but the winning gallery or falls anywhere but on or beyond the service line of the hazard side; the purpose is to give the opponent a chance to make a better shot before he loses the point.

The serving is done entirely on the service side, and the ball, on service, must strike on the roof of the penthouse. Points are scored by making a placement on the floor, by a service ace, and by hitting into the winning wall openings. Points are lost by hitting the ball into the net or out of court above the play line high on the walls, or by failure to reach the ball and return it. The player winning six games, sometimes eight, takes the set; and matches are decided by the best of three sets or the best of five in championship play.

Jay Gould, amateur champion from 1906 until he retired in 1926, and the only amateur in history to win the world title, and Tom Pettitt, professional who won the world championship, were the two greatest players developed in the United States. Pierre Etchebaster, a French Basque living in the United States, was the world champion in 1928 and for a quarter century thereafter.

### PADDLE TENNIS

Frank Peer Beal, a fourteen-year-old boy in Albion, Mich., who lacked the space to build a lawn tennis court in his backyard, conceived the idea of a paddle tennis court in 1898. In 1921, then associate minister of the Judson Memorial Church in Washington Square, New York, he laid out courts on the floor of the church gymnasium. With the cooperation of the department of parks, the game was later introduced into public parks, playgrounds, and supervised play streets. The American Paddle Tennis Association was organized in 1923, becoming the United States Paddle Tennis Association three years later. Today the game is played outdoors and indoors throughout the country.

**Method of Play.** Paddle tennis has practically the same strokes, rules, scoring, and strategy as lawn tennis but can be played in a much smaller space. The dimensions of the senior court, slightly larger than the junior, are 44 ft. by 16 ft., the doubles court being 20 ft. in width. The net is 2 ft., 6 in. high at the center and 2 ft. 9 in. at the posts outside the side lines. Four service courts are marked out as in lawn tennis, extending 12 ft. from the net. Only one serve is permitted in senior play and two in junior. The paddle, or bat, is made of laminated plywood. There is a perforated, metal-bound, oval-shaped paddle, 16¾ in. long, 8⅛ in. wide, and weighing 13 to 14 oz., but the cheapest and most commonly used is a rectangular bat measuring 14¾ by 7¾ in. It must not exceed 17 in. for senior play. The ball is approximately 2½ in. in diameter, which is about the same size as the lawn tennis ball, but it is made of light sponge rubber and is not so lively.

**Platform Paddle Tennis.** This all-year outdoor game was invented in 1928 by Fessenden S. Blanchard and James K. Cogswell of Scarsdale, N.Y. In 1932 the first open tournament was held, a year after the Fox Meadow Tennis Club of Scarsdale became the first club to put in courts. In 1934 the platform group organized as the American Paddle Tennis Association. The game spread throughout the country, particularly in sections where freezing temperatures and snow prevented winter-time activity in lawn tennis. The game is played on a permanent platform erected on a special foundation, and also on a portable platform which can be placed on top of a lawn tennis court. The dimensions of the platform court are the same as in paddle tennis. The platform itself is 60 by 30 ft. Backstops and sidestops measuring 12 ft. high enclose the court. Rules, scoring, and strokes of the platform game are the same as in the regular paddle tennis game, but because of the fact that the backstops are "in play" the strategy is quite different. Also, platform tennis is almost exclusively a doubles game.

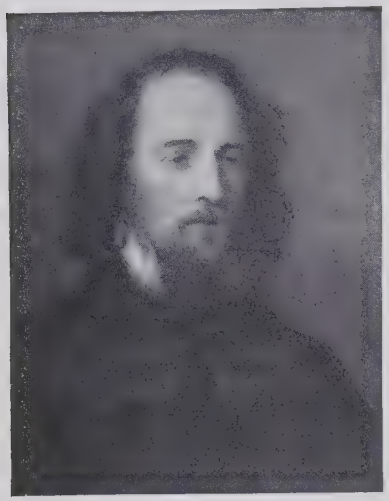
A. D.

**TENNYSON, ALFRED** [tɛ′nɪsən] (1809-1892), English poet, was born Aug. 6, 1809, at Somersby, Lincolnshire, the fourth of twelve children. Raised to the peerage in 1884 as Baron of Aldworth and Farringford, the title designating his residences in Surrey and the Isle of Wight, he is commonly styled Lord Tennyson. Poetry was his all-embracing interest from early youth until death, an interest strengthened, apparently, by family influence, the cordial appreciation of his early work by trusted friends, and his own success in winning the Chancellor's Medal at Cambridge in 1830.

The poetry of Tennyson may be divided roughly into three periods—one in which his interest was mainly lyrical, a second in which it was mainly narrative, and a third in which it was mainly dramatic. This division is approximate, however, since outstanding exceptions occur in each period. Tennyson's lyric period culminated with the publication of *In Memoriam,* in 1850, the year of his appointment as Poet Laureate and of his marriage to Emily Sellwood, to whom he first became engaged in 1837. Until 1842 it was a period of obscurity, marked by the hostility of critics and by the personal sorrow and perplexity that family problems and the death of his beloved friend A. H. Hallam brought upon Tennyson; it was made more oppressive by the sensitivity of his temperament, which belied his massive, athletic physique. In 1827 Tennyson and his brothers Frederick and Charles published a volume of poetry anonymously, which they entitled *Poems by Two Brothers,* although it contained contributions from all three. *Poems, Chiefly Lyrical,* containing *The Poet,* which set forth Tennyson's poetic creed, and *Mariana,* appeared in 1830 and was followed, at the end of 1832, by another volume, *Poems,* notable for *The Lotos Eaters* and *The Lady of Shalott.* Hurt by the rough critical treatment that the second volume received, and deeply shocked by the death of Hallam in 1833, Tennyson preserved silence for the next ten years, except for occasional contributions to the then popular "annuals." He broke this silence with *Poems* (1842), containing *Locksley Hall, Ulysses,* and *Morte D'Arthur,* which brought him general acclaim. In 1845 Tennyson received a pension from the English government, and in 1847, *The Princess* added to his fame.

The narrative period in Tennyson's work, which extends from 1850 to 1875, embraces the publication of *Maud and Other Poems* (1855), a collection in which the perennially popular *The Brook* first appeared, *Enoch Arden* (1864), and the greater part of *Idylls of the King* (first four idylls published in 1859). The third period began in the 1870's,

when Tennyson became absorbed in poetic drama and produced his first play, *Queen Mary,* in 1875. It was followed by six more, all of them except *Harold* being staged with more or less success, but they are now little known and have moved into the realm of closet drama. Tennyson devoted substantial time and thought to them, especially to *Queen Mary, Becket,* and *Harold,* which he envisaged as a trilogy portraying the making of England.



*ALFRED TENNYSON*

FROM AN ENGRAVING BY J. STEPHENSON OF A PAINTING BY G. F. WATTS

COURTESY OF THE NEW YORK PUBLIC LIBRARY

The poet's old age was one of astonishing vitality and productiveness, manifested in the publication of five volumes between 1880 and 1892. The last part of *Idylls of the King* appeared in 1885 and *Crossing the Bar* in 1889. Tennyson died Oct. 6, 1892, at Aldworth, and was buried with ceremonial honors in Westminster Abbey.

By virtue of his irreproachable personal and domestic life, his eloquent and frequent expressions of noble ideals, his felicitous descriptions and interpretations of nature, his abounding patriotism, and his sense of responsibility to the public, he represented, especially after his appointment as laureate, an ideal of the poet widely held in England and the United States in the nineteenth century. His relations with Queen Victoria and the royal family were almost those of an intimate friend, and with the public generally he was enormously popular. Becoming a legend in his own time, he was sought out by tourists from abroad, particularly from the United States, much as if he were the object of a holy pilgrimage. To later critics this situation has seemed unfortunate because it suggests that Tennyson allowed himself to be molded too much by the taste of his era. He thus did not, perhaps, realize completely his pre-eminent ability as a lyricist and as a master of metrics, and his intuitive perception of the awe-inspiring mysteries and sublimities of life and the universe was not fully expressed. He enjoyed a reputation as a thinker and seer which is not borne out by his writings, but there is a measure of justice in the opinion held by some scientists of his age that he was the one poet to understand science. *See also* ENOCH ARDEN; IDYLLS OF THE KING; IN MEMORIAM; MAUD; PRINCESS, THE. R. B. D.

**TENOR,** a term in music for (1) the highest male voice produced naturally; (2) the second lowest part in four-part writing; (3) members of the trombone, saxophone, and other instrumental families corresponding roughly to the tenor voice in range; and (4) that voice in early polyphonic music which carried the *cantus firmus* or "theme," against which the other voices sang contrapuntal variants. W. Li.

**TENREC** [tɛ'nrɛk], a large insectivore of the family Centetidae, restricted solely to Madagascar. The tenrec resembles the hedgehog in outward appearance, though lacking the spines of the latter. The animals are sparsely covered with coarse hairs; in some species the dorsal hairs form stout bristles. Tenrecs are prolific animals, occasionally bearing 15 or 16 young at a birth; a female carrying 25 embryos has been recorded. During the dry season the tenrec remains in its burrow, passing several months in a semitorpid condition which may be likened to hibernation. The tenrec's food consists of a variety of small insects and grubs. W. J. Ha.

**TENSE AND ASPECT.** The verb in the modern Western languages is divided into tenses which have as their main (although by no means unique) function to indicate time. Every English, French, or Italian verbal form is in the present, past, or future tense. In English, the most rational of European languages, tense has reached an apex of logical consistency; apart from the type *I have seen* (which is a variety of the present), English has but one present (*I see*), one past (*I saw*), and one future (*I shall see*). The element of time is so important in the verb that as early as the fourth century B.C. Aristotle declared that it was the verb's characteristic feature—a statement that was much less true for the Greek of his time than it would be for Modern English. German grammarians, when they had to create a grammatical term for the verb, called it *Zeitwort.* In fact, there is no other part of speech in which time is expressed by structural modifications.

Tense, however, is a relatively late development in the history of language, for consideration of time is a characteristic of an adult, mature, and intellectualistic mind. Primitives, like children, know little about time, and care less. Primitive Indo-European seems to have had no tenses in our modern sense, that is, no temporal expression whatever. Verbal inflection in Indo-European drew distinctions on another, quite different basis, *aspect,* i.e., manner of the action, or the way in which the action expressed by the verb takes place.

There were and there are still in some languages many types of aspect: ingressive, effective, terminative, unique, intensive, iterative, and others; the two most important ones are, however, the imperfective, indicating that the action has not reached it goal, is not accomplished, and the perfective, indicating that it does reach its goal. Among the modern Indo-European languages, the Slavic tongues have best preserved this system: almost every Slavic verb has at least these two aspects, and sometimes more. What is in English a lexicological distinction—*to talk: to say; to look: to see; to listen: to hear; to beat: to kill; to walk: to go*—is in Slavic a morphological distinction of primary importance; in each of these pairs of verbs the first may be taken to be the imperfective aspect of the second, the perfective. A man can talk a long time and say nothing; he can walk days and days and go nowhere. Likewise, *call, cry, shout, shriek,* and *scream* can each be considered a different aspect of the same verbal action. English has still other means of expressing different aspects, such as *he starts eating* (ingressive), *go to sleep* (ingressive), *he stops crying* (effective), *they hunted him down* (perfective; but in *they hunted all day long, hunted* is imperfective); and similarly, *dry out, rinse out, lie down, stand up, burn up.* Periphrases with such words as *grow, turn, wax, get, cease, stop, continue,* and *keep* are also used. In Slavic the perfective aspect, i.e., the concrete, particular, precise way in which a general, indeterminate action or trend finds its end, is frequently expressed by a

preposition prefixed to the imperfective stem. In English the type is *they hunted him down, he tore it away, they broke it up, look up, wipe off;* it is frequent in Latin, and also in German (e.g., *jagen: erjagen; schreiten: überschreiten; reisen: verreisen*).

Clear traces of this aspectual, tenseless era can still be clearly seen in Greek, Latin, and the modern Western languages. The opposition between aorist and present in Classical Greek, outside of the indicative mood (where time was indicated by the augment ε-), was aspectual, not temporal (e.g., the imperatives γράφε and γράψον; the subjunctives γράφω and γράψω). Likewise the whole Latin verbal system is based on the opposition of two stems—called by some linguists *infectum* and *perfectum*—which represent two different aspects, each of them with a present (or preterito-present), a future, and a past: *fac-io, fac-iam, fac-iebam; fec-i* (cf. *od-i, nov-i*), *fec-ero, fec-eram*. This aspectual opposition is still quite clear in the Latin of Republican times, and weakens only later. Sometimes, as frequently in Slavic, two or even more different stems are coupled together to express an opposition of the same sort: in Latin, for example, in *sum, ero, eram: fui, fuero, fueram;* in Greek, in ὁράω, εἶδον, ὄψομαι; and even in English (transformed into tenses), in *I am, we are, I was, I be,* and *I go, I went*. The originally timeless character of the English preterit can still be seen in such preterito-presents as *he can, he may, he will, he shall* (cf. *he saw, he gave, he ate;* also Latin *odi, novi, memini;* German *er mag, er kann, er soll, er will, er darf*). The recent character of the future tense in English can still be observed in its clumsy and inadequate expression of future time, illustrated in the well-known disastrous cry of the drowning man: *I will drown and nobody shall save me!* The heavy German future with *werden* (not very much used even now) is also recent; Proto-Germanic and even Gothic had no future tense.

English has, in addition to other forms, the so-called "expanded" form of the verb, also called "progressive," which is built periphrastically with the gerund and the verb *to be*: *he is eating, he is working*. This form usually expresses duration, though not in the sense that the action expressed by it lasts longer than the simple form. Sometimes it lasts much less long, as in the sentence *Augustus reigned forty-five years: while he was reigning, the Roman legions suffered a disastrous defeat.* But the form expresses duration in the sense that the mind of the reader lingers on the action, describes it, and develops it, whereas the simple form merely sums it up abstractly as a unique whole: *he died the evening of the 30th of December; he was dying the evening of the 30th of December*. The expanded form corresponds therefore to a certain extent to the Slavic imperfective aspect and to the French and Italian imperfect tense, while the simple form (especially in the past) corresponds to the Slavic perfective aspect and the French and Italian *passé défini, passato remoto: he ate, il mangea, mangiò; he was eating, il mangeait, mangiava*. The simple form frequently indicates that the action is accomplished (*Peter went to Washington* means that he really arrived there); the expanded form, that the action is not accomplished (*he was going to Washington* may mean that he never reached the city). The element of duration is almost always inherent in the imperfective aspect, the element of nonduration or instantaneity in the perfective (*he got up*). When one or the other of these elements predominates, we speak, respectively, of linear or punctual aspect. The element of time can here be seen penetrating into the aspect, but in the sense of duration, not in the chronologically defined senses of present, past, and future.

English possesses also, according to some scholars, an intensive aspect in the periphrastic construction with *do* (outside of the interrogative and negative clauses, where it is usual and therefore not expressive): *Do you see the ship? I do see it. Do go, please.*

Aspect is an extremely delicate grammatical category, one that is exceedingly difficult to define. It presents innumerable strange and contradictory facts, and has been the object of endless and often useless discussion. It can be truly said that aspect is as manifold as human sensations and images, and that every verb has, in a sense, its own aspect. G. B.

**TENSOR** [tɛ′nsər], in mathematics, a quantity having components in each of a given set of co-ordinate systems, the components in any one system being related to those in any other system by a prescribed law. Tensors include vectors and scalars as special cases. They are defined in geometrical spaces of any number of dimensions and play an important role in differential geometry, relativity, and certain branches of mathematical physics.

As an example, consider the vector in $n$-dimensional space whose components in the $x$-co-ordinate system are $\xi^i$ ($i = 1 \ldots n$) and whose co-ordinates in the $x'$-co-ordinate system are $\xi'^i$. Let $x'^i = f^i(x' \ldots x^n)$ relate the two co-ordinate systems. If the respective components are related by the law

$$\xi^i = \sum_{j=1}^{n} \frac{\delta x^i}{\delta x'^j} \xi'^j \quad ,$$

then the vector is called a contravariant vector. Similarly, if the relation is

$$\xi_i = \sum_{j=1}^{n} \frac{\delta x'^j}{\delta x^i} \xi'_j \quad ,$$

the vector is called covariant.

A general tensor has the form $T^{i \ldots j}_{a \ldots b}$. Its law of transformation is:

$$T^{i \ldots j}_{a \ldots b} = \sum T'^{r \ldots s}_{c \ldots d} \frac{\delta x^i}{\delta x'^r} \cdots \frac{\delta x^j}{\delta x'^s} \frac{\delta x'^c}{\delta x^a} \cdots \frac{\delta x'^d}{\delta x^a}.$$

It is said to be contravariant in the indices $i \ldots j$, and covariant in the indices $a \ldots b$.

Two geometrical examples of tensors are as follows: (1) the coefficients of the first and second fundamental forms of a curved surface; these are covariant tensors with two lower subscripts; i.e., they are covariant of the second order. (2) the coefficients of any quadratic algebraic form, such as

$$a_{11}x^2 + 2a_{12}\,xy + a_{22}y^2,$$

relative to linear co-ordinate transformations.

Two physical examples of tensors are as follows: (1) the inertial tensor whose components are the moments and products of inertia of a rigid body; (2) the stress tensor whose components describe the stresses exerted upon an elastic body by external forces. This latter application contributes the name tensor to this concept. *See also* DIFFERENTIAL GEOMETRY; VECTOR ANALYSIS. C. B. A.

**TENT CATERPILLAR,** the common name given to the larvae of certain moths of the family Lasiocampidae, which build tents in which they spend the day, coming out toward evening to feed. The common tent caterpillar, *Malacosoma americana,* and the Great Basin tent caterpillar, *M. fragilis,* are the two best-known tent builders. The eggs are

laid in a mass surrounding the twig of the food plant. As soon as they hatch, the young larvae build a silken nest, which is enlarged as they grow; when they leave the nest to feed, each spins a silken thread which it follows on the return trip. The forest tent caterpillar builds no nest; both the adults and the larvae resemble the tent-building caterpillars in general appearance, and caterpillars of the two groups may feed together on the same tree. The chief food of the tent-makers is wild cherry, but they also feed on other fruit trees. Wild cherries, when defoliated, bring forth a new crop of leaves, but in orchards tent caterpillars may cause serious damage. The forest tent caterpillar feeds on a wide variety of deciduous trees. Arsenical sprays destroy the larvae; in another method of control, the tents may be burned with a torch to destroy the young larvae. C. H. Cu.

*TENT CATERPILLARS*

**TENURE, LAND.** *See* LAND TENURE.

**TEOTIHUACÁN.** *See* TOLTEC.

**TEPHILLIN** [təfɪ′lɪn] (Eng. phylacteries), two small leather boxes containing pieces of parchment upon which passages from the Torah (Exod. xiii:1-10, 11-16; Deut. vi:4-9; xi:13-21) are written. Tephillin are worn by Jewish men above the age of thirteen and have leather straps attached to them, by which they are tied to the forehead and the left arm. In ancient times they were worn on all occasions, but later only at daily morning prayers; they are not worn at all on Sabbaths and festivals. The etymology of the word *tephillin* is uncertain, but possibly the word is connected with the Hebrew word *tephilah* ("prayer"). The use of the tephillin is based on the Biblical injunction "And thou shalt bind them [the preceding words] for a sign upon thine hand, and they shall be as frontlets between thine eyes" (Deut. vi:8). Reform Jews interpret this passage figuratively and do not wear the tephillin.

Together with the tephillin, the *tallith,* a prayer shawl, is worn; but unlike the tephillin, the tallith is worn also at the morning services of Sabbaths and festivals. The tallith is a fringed mantle, made of silk or wool. It varies in size, large ones being big enough to envelop the wearer. The significant feature of the tallith is the long fringes (Heb. *zizith*) at the four corners, which fulfill the commandment "bid them that they make fringes in the borders of their garments" (Num. xv:37). Orthodox and Conservative Jews also wear a fringed undergarment known as *tallith ḳatan* ("small tallith").

While it is possible that in very early times both the tephillin and the fringes had talismanic or magical significance, there is no such suggestion in the Bible or in other Jewish literature. The purpose of both is mnemonic; they are meant to remind the wearer of God's presence and of His word. D. G. and G. W.

**TEPLICE** [tɛ′plɪtsɛ] (Ger. Teplitz-Schönau), formerly Teplice-Sanov, a noted resort center and industrial city in northwestern Czechoslovakia. It is on the southern slopes of the Ore Mountains, 12 mi. west of Ustí nad Labem and about 50 mi. northwest of Prague, in the heart of the Bohemian lignite mining area. The local industries of the town, largely German since medieval times, brought in Czech laborers during the late nineteenth century under Austro-Hungarian rule. In 1925 large numbers of Czechs came into the area at the instigation of Czech authorities, who had controlled it since 1918. A strong German center, it was within the Sudetenland that went to Germany after the Munich agreement in 1938 and was returned to Czechoslovakia in 1945. A beautiful medieval castle and its gardens are noteworthy sites, and hot springs, known since A.D. 762, make Teplice one of the most popular resorts in Czechoslovakia. There are rail and highway connections to Ustí nad Labem, Most, and Prague. In Teplice and its neighboring villages considerable lignite is produced, in addition to glassware, metal goods, textiles, and food products. The German population was sent back to Germany during 1946 and 1947 and was replaced by Czechs. Pop. 1947, 45,183. F. Sc.

**TEQUENDAMA FALLS** [te′kendɑ′mɑ], a waterfall 16 mi. southwest of Bogotá, Colombia, formed as the Río Bogotá drops over a 475-ft. precipice in a mass of spray. It is one of the most beautiful falls in the Americas. In Chibcha legend, the god Bochica created it to drain away flood waters. A smaller cataract above the falls provides electricity for Bogotá. P. E. J.

**TERAH** [ti′rə], in the Old Testament, the father of Abraham, Nahor, and Haran (Gen. xi:26). He emigrated from his native city, Ur of the Chaldees, to the city of Haran in Syria, and died there at the age of 205. Jewish tradition, based on Joshua xxiv:2, makes of Terah not only an idol worshiper but a maker of idols, and this estranged him from his son Abraham, who was a firm believer in the Lord. M. A. G.

**TERAMO** [tɛ′rɑmo], a province and also the capital city of that province, in an agricultural area in the region of Abruzzi e Molise in east central Italy, on the Adriatic slope of the Apennines.

**The City.** Teramo lies midway between the Monte della Laga and the Adriatic Sea, at an elevation of 900 ft. above the level of the latter and about 40 mi. northwest of Chieti. Teramo rests on a tongue of high land formed by the junction of the Tordino and Vezzola rivers. The older and lower part of the city has the narrow and crooked streets of a medieval town, while the new and upper portions are more spacious and open. The climate is characterized by mild winters and hot summers; the annual rainfall averages 34 in. The city is essentially a market place and administrative center for the circumjacent agricultural zone and is connected with the main Adriatic railway line by a branch connecting at Giulianova. The Romanesque cathedral, started in the twelfth century and restored in the fourteenth, and its cam-

panile, as well as one of two medieval churches, constitute the outstanding monuments of the city. Roman remains, including a theatre of Hadrian's epoch, have been unearthed. Built on the site of ancient Interamna (Interamnia, Teramne), the medieval and modern city of Teramo has undergone the succession of rulers, chiefly foreign, common to the Abruzzi. The city was undamaged in World War II. Pop. (off. est. 1947) 38,190.

**The Province.** The province of Teramo, comprising 45 communes, has an area of 752 sq. mi. It extends from the Adriatic Sea to the heights of the Apennines (Gran Sasso); on the south it is bordered by the province of Pescara and on the north by the Marches. Approximately 45 per cent of the province is classified as mountainous; most of the remainder is hilly, since the coastal plain is quite narrow. Wheat and grape culture predominate, but some olives, vegetables and other fruits are also grown. Cattle, sheep, and swine are raised. Nearly three-quarters of the working population is engaged in agriculture; industry is hardly represented at all. There are no towns of any size in the province except Teramo. Pop. (est. 1947) 270,000. R. G. W.

**TERBIUM.** *See* RARE EARTHS.

**TERBORCH, GERARD** [tərbɔ′rχ] (1617-1681), Dutch genre and portrait painter, was born in Zwolle, Holland, in 1617. He studied first under his father, and from 1632 to 1635 under Pieter de Molijn in Haarlem. He traveled to England in 1635, to Italy in 1641, and to Amsterdam about 1645. He was in Münster from 1646 to 1648, where he portrayed the ratification of the Treaty of Westphalia by Philip IV, and then he went to Spain, where he was knighted by Philip. He returned to Zwolle in 1650 for a few years' stay, and finally settled in Deventer.

Excelling in small-scale portraiture, Terborch revealed the personality of his subjects with dignity and intimacy. His most characteristic works are single-figure or small-group genre scenes of fashionable ladies engaged in reading or writing letters, playing the lute, or indulging in similar pastimes. In soldier-scene paintings he developed early the silver-gray flesh halftones and the shimmering reflected highlights which keynote his style. Color was applied sparingly and glazed by degrees to produce the rich, molten effect that defines the play of light and shadow over tapestries, furs, and satins. Terborch died in Deventer Dec. 8, 1681. R. A. K.

**TEREDO** or **SHIPWORM** [təri′do], the popular name for members of the family Teredinidae of bivalve mollusks, which live in sea water and often damage wooden ships, docks, and other submerged wooden structures. Most shipworms have elongated wormlike bodies that sometimes reach a length of several feet. The sexes are separate. Fertilized eggs are released by the parent after they reach a certain stage of development. The embryos are carried by the currents, and if they come in contact with wooden structures they immediately try to burrow into the material by spasmodic openings and closings of the shell valves. In four or five hours an embryo can be hidden from view. Soon after the embryo buries itself in the wood it changes its shape and begins to grow, rapidly excavating long burrows. If the infestation is severe, a piece of wood may be virtually honey-combed by the burrows, which are made by a rasping motion of the shells. The burrows are lined with a calcareous coating. *Teredo thompsoni* and *T. chlorotica,* small-sized shipworms, are common from Maine to Florida. Those of the related genus *Bankia,* especially *B. setacea,* which is common from Alaska to San Francisco, are the largest North American shipworms, reaching a length of 4 ft. V. L. L.

**TEREK** [tyre′rık], a leading river located in the pre-Caucasus in the southwestern Soviet Union. With a length of 371 mi., it rises on the north slope of Mt. Kazbek as the Res Don, at an elevation of over 11,500 ft., and flows east and then north as a mountain stream through the Daryal Pass (7,940 ft.) forming the route of the Georgian Military Highway through the forested mountains to Ordzhonikidze (formerly Vladikavkaz). Below this city it enters the lowlands and turns abruptly east and later northeast to its delta on the Caspian Sea. The river drains an area of 23,053 sq. mi. Its only right-bank tributary is the Zunsha. Left-bank tributaries include the Ardon, Uruk, and Macka. Principal cities along its banks are Ordzhonikidze and Mozdok. The river is navigable 254 mi. above its mouth to its junction with the Macka, and floods are frequent in its lower course. C. C. H.

**TERENCE (PUBLIUS TERENTIUS AFER)** [tɛ′rəns] (c. 195-159 B.C.), Roman comic dramatist, was born in Carthage, brought to Rome as a slave, and there freed. He became an intimate friend of Scipio, in whose circle were statesmen and men of letters interested in improving and refining Latin. Terrence's six comedies, *fabulae palliatae* like those of Plautus and likewise adapted from the Greek New Comedy, were produced in 166-160 B.C. The *Andria* (*The Lady of Andros*), *Heauton Timorumenos* (*The Self-Tormentor*), *Eunuchus* (*The Eunuch*), and *Adelphoe* (*The Brothers*) were based upon originals by Menander; the *Phormio* and *Hecyra* (*The Mother-in-law*) upon originals by Apollodorus. In 160 B.C. Terence made a journey to Greece, where he died the following year.

Terence's comedies have a spirit very different from that of the Plautine dramas. They contain little song and dance, and lack the broad humor and farcical treatment to be found in the work of the older playwright; the language is less vigorous and racy than that of Plautus and jests and puns are rare. Terence's humor is not derived from exaggerated characterizations and laughable situations, but is the same "thoughtful laughter" which George Meredith considered typical of Menander and Molière. Although lacking the range and variety of Plautus, Terence's treatment of plot and character is far more subtle. There is less trickery and more use of mistaken identity and recognition, a practice in which Terence was following the example of Menander. The slaves, unlike the intriguing and insolent servants in Plautus, are sometimes deceived or kept in ignorance of the truth. The fathers are more dignified and reasonable, and their confusions and misunderstandings develop naturally from the situation, as in the *Phormio, Hecyra,* and *Adelphoe.* The courtesans are often portrayed as generous and noble, as are Thais in the *Eunuchus* and Bacchis in the *Hecyra,* and even more unconventional is Terence's delineation of Sostrata, the patient and self-sacrificing mother-in-law in the *Hecyra.* An outstanding feature of Terence's dramatic technique is the dual plot, in which the two love affairs of the two young men, often brothers or cousins, are interwoven; the happy solution of the one love affair is dependent upon that of the other. All of Terence's comedies except the *Hecyra* have this dual plot.

One of Terence's most striking innovations was his use of the prologue. Plautus in his prologues had given the background of the plot and had often made a humorous appeal for the audience's favor; Terence, on the other hand, elimi-

nated from the prologues all reference to the plot and made them chiefly a defense against the unfavorable criticism of other dramatists, especially that of a playwright named Lucius Lanuvinus. He referred to his practice of adding a part from a second Greek original and defended this procedure, known as *contaminatio,* by the example of his predecessors, Naevius, Plautus, and Ennius. Partly by his omission of the plot from the prologue and partly by his handling of the action, Terence, as in the *Phormio* and the *Hecyra,* often kept the spectator in the dark concerning the secrets of the plot and made him experience the same confusion and uncertainty as the characters; in this way he was able to create more suspense than had Plautus and the Greek playwrights.

The art of Terence was far more Greek than Roman; his plays lacked the Italian qualities of Plautus and contained no allusions to Roman localities or events. Terence wished to reproduce as faithfully as possible the thought and expression of the Greek originals. He was a dramatist with a high ideal of artistic perfection, and he did much to bring elegance and restraint to the Latin language. Caesar praised him as "a lover of faultless speech" (*"puri sermonis amator"*), and his maxims (*sententiae*) lent themselves to frequent quotation by later writers: "Fortune favors the brave," "A word to the wise is sufficient," "So many men, so many minds," "The quarrel of lovers is the renewal of love," "Where there's life, there's hope." Like Plautus, Terence had a great influence on Renaissance dramatists; Molière made adaptations of the *Phormio* and the *Adelphoe,* and the influence of his plays upon English playwrights of the seventeenth and eighteenth centuries was partly direct and partly indirect through Molière. G. E. D.

**TERESA DE JESÚS, SANTA** [tere′sə the hesu′s] (1515-1582), Spanish mystic and saint, was born in the Castilian town of Avila, Mar. 28, 1515. She was christened Teresa de Cepeda y Ahumada. In her later works, many of them autobiographical, she relates her avid childhood reading of lives of the saints, and such romances of chivalry as *Amadís de Gaula,* a book which inspired the imagination of almost every Spaniard of the time. Her mother died when Teresa was twelve, and this loss, along with her subsequent education at an Augustinian school, and, in particular, her reading of St. Jerome, confirmed her spiritual vocation. In 1534, accordingly, she entered the Carmelite convent in Avila, where she submitted her sickly disposition to the required ascetic exercises with such zeal that her health was impaired, and she suffered an illness which was to recur throughout her life. Her first experiments in contemplation led to a long period of indecision and hesitancy, a period which ended, she writes, only after her reading of St. Augustine. In 1556 a period of intense mysticism began, and she experienced a number of divine visions, one of which, a vision of Hell, led her to undertake the reform of her order. In 1562 the first convent of reformed or discalced (barefoot) Carmelites was opened, and Teresa's continued efforts on behalf of the movement brought such a storm of opposition from followers of the older rule and their supporters that in 1578 she was denounced to the Inquisition and confined in Toledo. Her disciple, John of the Cross, who undertook a similar reform among the male Carmelites, was made to suffer an even more harsh imprisonment at the same time. During the long, active period of the foundations of her movement, Teresa's progress along the paths of mysticism continued, and it is her integral combination of the practical and mundane with a spiritual vocation that marks her greatness. The reform of the Carmelites achieved complete triumph in 1580, when Philip II intervened and caused the reformed branch to be established as a separate monastic province. Teresa died at Alba, Oct. 4, 1582, and was canonized in 1622.

The autobiographical works of Santa Teresa can be understood only when it is realized that they were not written for publication, but rather at the request of her various confessors and spiritual mentors. Of these, the *Libro de su vida* ("Book of Her Life") was written in 1566 and published at Salamanca in 1588 after her death. The *Libro de las fundaciones* ("Book of the Foundations"), which she began in 1573, was not published until 1613. Santa Teresa's more than four hundred letters reveal even more intimately the texture of her personality: realistic diplomacy, humor, and an intimate poetic imagination emerge without conflict from an inner realm of complete spirituality. Santa Teresa's works of mysticism, her doctrinal expositions, are at once exalted and familiar, but never technical. Particular mention should be made of two books: *Las Moradas* ("The Dwelling Places"), written in 1577 and published in 1588, an allegory of mystical progress which describes the seven-chambered "interior castle" of the soul; and the *Camino de perfección* ("Path of Perfection"), published in 1583, which advises nuns in the practice of contemplation. These books, like those of autobiography, were written for an intimate circle of disciples and friends and were not intended for wide circulation. They were composed with tremendous speed and were organized with an intuitive rather than a rhetorical or formal logic. The homely metaphors, provincialisms, and sudden insights of Santa Teresa's style present the entire being of the woman in action. Her works have in this way a special human clarity unknown to many writers of doctrine. Their importance is not only ecclesiastical but literary, and today they are ranked by readers of all faiths as among the prose masterpieces of the Spanish language. *See also* CRUZ, SAN JUAN DE LA. S. G.

**TERESINA** [terəzi′nə], an industrial city and the capital of the state of Piauí, in northeastern Brazil, situated on the Parnaíba River, about 270 mi. south of the port city of Parnaíba. The city has direct air and river transportation facilities, and rail service from Senador Furtado across the river to the port of Sao Luis. The local industrial output reflects the region's produce, with sugar and cotton products among the most important items. Pop. 1950, 51,418. S. G. I.

**TERMAN, LEWIS MADISON** [tɜ′rmən] (1877- ), American psychologist, was born in Johnson Co., Ind., Jan. 15, 1877, and was educated at Indiana University (A.M. 1903) and Clark University (Ph.D. 1905). After teaching in public school and normal school, he went in 1910 to Stanford University where he was professor of psychology from 1916 until his retirement in 1942, and head of the department for twenty years. He received honorary doctorates from Indiana University (1929), the University of California (1945), and the University of Pennsylvania (1946) and was president of the American Psychological Association in 1923. He is widely known for his two "Stanford" revisions of the Binet mental tests (1916, 1937), for their use in selecting superior children whose personality and later careers he studied, and for other ability and personality tests he devised and applied. He was author or co-author of *The Measurement of Intelligence* (1916), *The Intelligence of School Children* (1919), *Mental and Physical Traits of 1000 Gifted Children* (1924), *The Early Mental Traits of 300 Geniuses* (1926), *The Promise of Youth* (1930), *Sex and Personality* (1936),

*Measuring Intelligence* (1937), *Psychological Factors in Marital Happiness* (1938), and *The Gifted Child Grows Up* (1947). F. A. K.

**TERMINUS** [tɜ′rmɪnəs], a Roman god of boundaries and property limits represented by a stone or post set in the ground with appropriate ceremonies. Sacrifices were annually offered at these boundary stones, at the festival of the Terminalia, on February 23. Originally Terminus was probably an epithet of Jupiter, and his statue, or sacred boundary stone, stood at Rome in the temple of Capitoline Jupiter. G. E. D.

**TERMITE,** the name given to any member of the insect order Isoptera. Another common name is "white ant," but termites are not ants and are readily distinguished from them: in termites the abdomen is joined to the thorax in almost its full width and the wings have numerous veins; in ants, the abdomen is joined to the thorax by a slender waist and the wing veins are few in number.

**Colonial Organization.** Termites are social insects, and their colonies may consist of a few dozen to many hundreds of thousands of individuals. In the simplest colony there may be found only a queen, a king, and many workers, but most colonies contain at least two types of workers, one with the head greatly enlarged; this type both works and fights. In the more complicated colonies there are many different classes of individuals: the king and the queen, the fertile male and female which originally established the colony; the supplemental reproductives, which are also fertile but are smaller than the king and queen and may be either short-winged or wingless; and, making up the rest of the colony, the workers and soldiers, both of which are sexually undeveloped females, pale-colored and wingless. The soldiers are larger than the workers and may occur in two types: those with large mandibles and those with the front of the head prolonged into a snout.

Although all the reproductives lay eggs, the queen usually lays the greatest number, in some species a total of as many as 30,000 a day. The winged sexual forms usually develop once a year; they are brownish in color, have a hard integument, and are able to stand bright sunlight. After mating, or in some species before, they search for a suitable place in which to establish a new colony, and they then dispose of their wings, which, weak at the base, are easily broken off.

**Termitaria.** All termites build nests either underground or above ground. The dry-wood termites feed on dead wood, and their nest is a maze of tunnels within the material on which they are feeding. The forms that feed on the roots of grasses and other plants build large cemented-earth termitaria that may project several feet above the ground; those six-feet high are common in tropical areas, and there are many records of termitaria reaching a height of twenty-five feet. On the plains of Africa and Australia such termitaria are a menace on aircraft landing fields, and considerable difficulty has been experienced in eliminating them. The shape and structure of these termitaria vary with the different species.

**Food.** Termites feed for the most part on cellulose, which they cannot digest completely. Protozoans, which live symbiotically in the hind gut of the termite, digest the cellulose partially; the termite then digests the remainder. Since they live in a protein-poor environment, termites have been forced into a very strict protein economy, in which the old and decrepit members of the colony are consumed and even their own excrement is eaten.

**Biology.** Termites are essentially tropical insects, but a few kinds have spread to the temperate regions. In the United States the native termite is *Reticulitermes flavipes.* It is a subterranean species that builds its nest in the ground and normally feeds upon dead trees and branches, or dead areas in living trees, but it also feeds on the wood in buildings and sometimes causes serious damage. In the southern United States there are several species of dry-wood termites that nest

*Termites' nest in the Suk country, Kenya, East Africa*

in the wood itself; in the tropics there are dry-wood termites that build their nests in or upon dead areas of trees. If termites are unable to travel from their nests to the source of their food supply without coming into bright light, they build tunnels of wood and earth through which they can travel in safety. If these tunnels are broken, the soldiers protect the workers while the tunnel is being repaired.

**Value of Termites.** Although some kinds are injurious to man's home and crops, termites are for the most part beneficial, since they destroy dead wood which might otherwise remain on the forest floor for many years. Many kinds are eaten as a staple food diet in Africa and other tropical regions: in the Congo the natives have their own termitaria from which they annually collect the sexual forms as they emerge for their nuptial flights. The queens, which may exceed an inch in length, are highly prized as food in many parts of the world; they are usually eaten raw. C. H. Cu.

**TERN,** any one of a large aggregation of species of medium-sized to small (9 to 24 in.) web-footed sea birds of the subfamily Sterninae of the family Laridae. They are mainly birds of the warmer coasts of the world, but a number of them range in season as far as the arctic and antarctic regions. They differ from their nearest relatives, the gulls, in their more slender bodies, their tapering, pointed bills, their longer, narrower wings, and their relatively shorter legs and smaller feet. Most species, especially the pelagic ones, have long, deeply forked tails. Their plumage forms combinations of black, white, and gray; it may have, in the

breeding period, a lovely roseate tinge on the breast. Terns are famous for their graceful flight, and they are often called "sea swallows." They seldom rest upon the water, but hover in the air until some small aquatic animal is sighted and then plunge upon it. They breed in colonies, depositing

L. A. FUERTES—U. S. FISH AND WILDLIFE SERVICE

*BLACK TERN*

their disproportionately large eggs in an unlined hollow on the beach, or, in the case of the fresh-water species, in a nest made of floating marsh vegetation. H. G. De.

**TERNATE** [tɛrnɑ′te], a small, heavily forested island, about 25 sq. mi. in area, lying off the central west coast of Halmahera Island, in Indonesia, at 1° N. lat. and 127° 30′ E. long. Ternate, one of the Moluccas, is a volcanic island with peaks rising to 5,600 ft. The chief town, also named Ternate (pop. 7,126), is located on the east coast. Settled by the Portuguese in 1521, it is an important port of call, long noted for its trade in spices. Other exports are rattan, teakwood, copra, and bird skins. Pop. (est. 1940), 20,000. R. G. B.

**TERNI** [tɛ′rni], a province and the capital city of that province, situated in the region of Umbria, in central Italy.

**The City.** The ancient city of Terni, which has become one of Italy's principal industrial centers, is located on the Nera River, a few miles below its confluence with the Velino. It is surrounded on three sides by the foothills of the Apennines, about 45 mi. northeast of Rome. Until 1879, when the metallurgical industry was established in the city, Terni was a small village. The chief industrial establishments of the metropolitan area produce munitions and war matériel, railway equipment, iron and steel products, chemicals, textiles, sugar, and rubber goods. The power for these industries is supplied by the hydroelectric power generated at the falls of the Velino and other near-by rivers. Because of its strategic industrial importance, Terni during World War II was subjected to over 120 Allied air raids, which destroyed more than half of the central part of the city. Known in Classical times as Interamna Nehars, the city was the home of the historian Tacitus. After the fall of Rome it was devastated by the Goths in A.D. 546, by the Byzantines under Narses in 553, and by the Lombards in 755. It continued to be a point of dispute among near-by states, including Spoleto and Narni, until 1420, when it came under the control of the Roman Catholic Church. In 1860 Terni was annexed to the Kingdom of Sardinia, which a year later became the Kingdom of Italy. Pop. (off. est. 1947), 82,183 (including suburbs).

**The Province.** Created in 1927, Terni Province comprises thirty two communes and embraces an area of 826 sq. mi. It lies entirely within the middle basin of the Tiber River, and its terrain is hilly, with low mountains of about 4,000 ft. in height near its capital. In spite of the concentration of industry in the capital area, agriculture is the chief activity of the province. About half the productive land is sown to crops such as cereals, sugar beets, and other vegetables, while one third is devoted to woodlands and one eighth to pasture land. The province is well supplied with rail and road communications. Pop. (off. est. 1947), 211,000. R. G. W.

**TERNSTROEMIA** [tɜrnstri′miə], a genus of warm-temperate and tropical evergreen shrubs, native to Asia, the Indian Archipelago, and America, and belonging to the tea family, *T. japonica,* native to Japan and India, and planted for its handsome bronzy foliage, grows in the southern United States, and is hardy as far north as San Francisco. It grows to about 20 ft. tall and is more treelike than shrubby. L. de F.

**TERPANDER** [tɜrpa′ndər], Greek poet and musician, was born at Antissa on the island of Lesbos. History has not preserved a large body of incontestably accurate information about Terpander, but scholars generally agree that he played an important part in the development of Classical music and lyric poetry in Greece during the first half of the seventh century B.C. A performer on the lyre and the flute, Terpander composed for both instruments. He is said by some to have been the first to have increased the number of strings on the lyre from four to seven, but others credit him only with the introduction into Greece of an improved lyre invented elsewhere. Terpander's poetry was for the most part in hexameters, but he made many metrical innovations, for some of which he was fined by the Ephori. He is credited with the development of the nome, a sacred poem sung in honor of a god to the accompaniment of the lyre and the flute. Terpander won first prize in the musical contests at the Carnean Games in 676 B.C., and, according to Plutarch, he won first prizes in the contests held in connection with the early Pythic Games. Some authorities attribute to Terpander the invention of musical notation and the beginnings of the science of musical notation, but this is widely contested. Terpander is often described as the father of Greek lyric poetry and Classical music. H. Bol.

**TERRA COTTA** [tɛ′rə kɒ′tə], literally Italian for "cooked earth." Clay baked for hardness and resistance to water may be called "terra cotta," although the term is sometimes restricted to the architectural and sculptural uses

of the material. It may be glazed for luster, color, figured decoration, and complete waterproofing, and it is then called "glazed terra cotta." The unglazed form is distinguished by the term "biscuit." Terra cotta was widely used in the ancient world, both Eastern and Western, as well as in pre-Columbian America. It was sufficiently important in Rome to be produced in provincial centers throughout the Continent and in England, but the art was virtually lost after the collapse of the Holy Roman Empire, until it was revived for architectural and sculptural use in the late Gothic period.

The architectural use of terra cotta was important in ancient Greece, probably as a result of the development of Greek building methods from primitive wood and mud brick forms. This use continued into the period of Greek architecture, when elaborately decorated gutters, antefixes, and water spouts were made of the material, as well as the alternating round and flat tiles of roofs. The ancient Persians and Assyrians, who never developed access to stone as the Greeks did, also made elaborate use of tile, especially to face mud brick walls. In modern times, when a surface from which city grime may be easily removed presents an advantage, glazed terra cotta has been used occasionally to face buildings. A fine example is Raymond Hood's elaborate decorative treatment on the American Radiator Building in New York City.

A clay object may be baked or modeled, but, if it is above a few inches in size, it is considered necessary to scoop out the inside of the heavier masses to provide a wall of as uniform thickness as possible, because shrinkages in drying and baking may cause warping and breakage. Terra cotta may be produced cheaply in quantity by making a baked clay or plaster mold of the original model, into which clay may repeatedly be pressed or poured at the proper consistency. The charming Tanagra figurines of the Hellenistic period were made in this manner. Because of technical difficulties in the firing process, it is now considered impossible to create clay sculpture larger than table size. However, at the dawn of Western Mediterranean history, the Etruscans made many large terra cottas, and a fine Etruscan figure of a warrior in the Metropolitan Museum, New York, is over life-size.

In the early Italian Renaissance a great deal of sculpture, in both glazed and biscuit terra cotta, was made to fill the widespread demand for art on the part of many small patrons of limited means. Luca della Robbia (c. 1400-1482) developed a style of glazed terra cotta, generally using white figures in relief against a blue background, surrounded by a panel of bright, naturally colored flowers and fruit. The style was continued by his descendants, with increasing elaboration, for a hundred years. French Rococo sculptors designed many small, gay figures and groups for reproduction in biscuit or glazed terra cotta at the national potteries of Sèvres, and this type of work, produced in various other centers of Europe, remained popular throughout the nineteenth century. *See also* ENGINEERING MATERIALS (*Brick and Clay Products*).

L. R.

**TERRAMYCIN.** *See* ANTIBIOTICS.

**TERRAPIN,** a variously spelled word, reputedly of Amerindian derivation, applied confusingly to many types of turtles, but most often to terrestrial tortoises or, contrariwise, to edible, fresh- or brackish-water species. British herpetologists subscribe to the latter usage, applying the term to any member of the Emydidae, or pond turtles. American herpetologists generally restrict it to the diamondbacks, *Malaclemys,* of the Atlantic and Gulf Coast salt marshes. The famous terrapin stew of epicures is obtained from the diamondbacks. Other excellent edible species are the cooters, of the genus *Pseudemys,* which frequent fresh-water rivers in the southeastern section of the United States. M. G. N.

**TERREBONNE** [tɛ′rbɔ′n], a town in Terrebonne Co., Quebec, Canada, situated on the north bank of Rivière des Milles Iles, 15 mi. north of Montreal, on Provincial Highways 18 and 29. It is connected by a bridge with St. François-de-Sales on Jesus Island and is served by the Canadian Pacific Railway. The seigneury of Terrebonne was granted in 1673, and the parish was founded in 1727. Incorporation as a village occurred in 1853 and as a town in 1860. The town was for many years the headquarters of the fur trade. Local manufactures include agricultural implements, machine tools, shoes, steel and fiber products, and sashes and doors. Pop. 1951, 3,200. D. F. P.

**TERRE HAUTE** [tɛ′rə ho′t], a city in western Indiana, the county seat of Vigo Co., situated on a plateau on the east bank of the Wabash River, 72 mi. southwest of Indianapolis. Coal mines and clay and shale deposits are in the vicinity. Terre Haute is the commercial and financial center of the surrounding coal-mining and farming area. A settlement started around Fort Harrison, erected at the beginning of the War of 1812, about 3 mi. north of the present city. Terre Haute was incorporated as a town in 1816 and chartered as a city in 1853. The city is administered by a mayor and council. The Chicago & Eastern Illinois, the Chicago, Milwaukee, St. Paul and Pacific, the New York Central, and the Pennsylvania railroads and the Trans-World Airlines provide transportation. Terre Haute's diversified plants include railroad shops, paper mills, distilleries, foundry and machine shops, and flour and grist mills. Penicillin, chemicals, solvents, men's clothing, distilled spirits, vitrified brick, tile, coke, enamelware, and bottles are produced in the city. Pop. 1950, 64,214.

**TERRELL** [tɛ′rəl], a city in Kaufman Co., in northeastern Texas, situated 35 mi. east of Dallas. It is a retail trade center for an agricultural area. Terrell was founded in 1873 and incorporated in 1885. It is administered by a council and city manager. It is the seat of Terrell State Hospital and Texas Military College. The Texas and Pacific and the Southern Pacific railroads provide transportation. The manufacture of flour and cottonseed oil and the ginning and baling of cotton are leading industries. Terrell also has creameries, candy and broom factories, planing mills, and machinery plants. Pop. 1950, 11,544.

**TERRESTRIAL MAGNETISM AND TERRESTRIAL ELECTRICITY.** Terrestrial magnetism, or geomagnetism, deals with the magnetic phenomena of the earth, which acts as a great spherical magnet. Terrestrial electricity deals with the electrical phenomena evidenced by the natural electric currents—earth currents—flowing within the earth, and by the electric field of the atmosphere—atmospheric electricity.

### HISTORY OF TERRESTRIAL MAGNETISM

**The Lodestone.** It is fortunate that there is distributed widely over the earth's surface a natural magnet in the mineral magnetite—an oxide of iron commonly designated as the lodestone. The discoveries of the lodestone's property of attracting iron and, later, that of taking a definite direction if freely suspended or floated were basic ones in realization of the geomagnetic field and of its economic applications.

Legends of "south-pointing" war chariots, now proved largely mythical by the thorough researches of A. Crichton

Mitchell, credited the Chinese with knowledge of the properties of the lodestone twenty-five centuries or more before the Christian Era. It is known, however, that by the fifth century B.C. the Greeks were aware of the property of the lodestone to induce magnetism in iron objects touching it. Thus, in Plato's dialogue *Ion,* Socrates says: "There is a divinity moving you, like that of the stone which Euripides calls a magnet. For that stone not only attracts iron rings but also imparts to them similar power of attracting other rings, suspended one from another, so as to form quite a long chain; and all of these derive their power from the original stone." Until about 1820, artificial magnets were made through this power of inducing magnetism merely, by stroking iron bars with other magnets or a lodestone. Then, the discovery that a magnetic field is produced by sending an electric current through a cylinder of many turns of wire, and that it will magnetize a bar of iron mounted within such a coil, resulted in the use of electromagnetization.

**The Compass.** About A.D. 1100, Europeans became acquainted with the directive property of the lodestone that gave birth to the invention of the magnetic compass. The polarity of the lodestone (or of a magnet made by its induction), its directive property in the geomagnetic field, and its application to navigation were first described by Alexander Neckam about 1187, in two treatises, *De utensilibus* and *De rerum naturis.* The first of these includes a description of the use of a magnetized needle to indicate the north, and the second gives the method of mounting such a needle on a pivot.

In 1269, Petrus Peregrinus de Maricourt wrote on his experimental results with a spherical lodestone and explained how the poles or centers of magnetic strength thereof could be determined. He mounted his lodestone in a floating wooden cup and noted that the stone would cause the floating cup to turn "until the north pole of the stone would come to rest in the direction of the north pole of the heavens." He observed further that no matter how often the cup was moved away from this direction, the lodestone would always cause it to return "by the will of God." He found, on cutting a lodestone in two parts, that each part became a magnet with two poles and that when these were put together again the two poles in the center disappeared.

The next major step in the history of terrestrial magnetism was the discovery that the direction assumed by a compass changes from place to place. The actual date of this discovery is uncertain, and it was not until 1581 that this fact appeared in print in an article by Robert Norman on *The Newe Attractive.* In 1576, Norman had also discovered that when a magnetized needle is mounted in a horizontal axle one end will dip below the horizon. The discoveries of these facts of magnetic declination and inclination led, before the end of the sixteenth century, to the first real recognition of the earth's behavior as a great magnet.

**Gilbert's Theory.** In 1600, William Gilbert, court physician to Queen Elizabeth, published *De magnete,* in which he summarized knowledge of the properties of magnetic bodies and advanced his epoch-making conception of the earth as a great magnet, thus antedating Newton's theory of universal gravitation by nearly a century. The conclusions were based on many experiments made with spherical lodestones and a small magnetic needle. Gilbert's theory explained the north-south position of the magnetic needle and, assuming the axis of magnetization to coincide with the axis of rotation of the earth, the change of geomagnetic dip or inclination with latitude. Gilbert also noted the influence of the lodestone at a distance and called the field of a magnet *orbis virtutis* (circle of power). There is no doubt that he was stimulated in his thinking by the earlier work of Norman, who had expressed the idea of a magnetic field as the "vertu extending rounde about the stone in great compasse." Gilbert's work is an outstanding contribution to magnetic science and is distinguished by adherence to the scientific method of investigation by experiment.

Soon the complexity was added to by the discovery that the compass direction at any fixed place undergoes a long-time, or secular, change. This fact was first noted by Henry Gellibrand in 1634.

**Early Geomagnetic Surveys.** Naturally, Gilbert's conclusions enlisted the efforts of many explorers and investigators in obtaining geomagnetic data in all parts of the known world. Among the possible applications, it was thought that the problem of determining longitude, for which chronometers were then not available, might be determined by the changes in magnetic variation, that is, direction or declination. This supposition led to the inception of a geomagnetic oceanic survey of the north and south Atlantic Ocean by Edmund Halley on the *Paramour* during 1698 to 1701, under the auspices of the British government, "to improve the longitude and variations of the compass." Halley originated the method of portraying by isomagnetic curves—lines along which values are equal—the distribution of the geomagnetic elements, although he used it only for declination. This classic chart was printed in 1700. Wilcke's chart of geomagnetic inclination was published in 1768. Charts delineating geomagnetic directive force resulted from Humboldt's observations on his American journeys during 1799 to 1804. These were the forerunners of the geomagnetic world charts now issued at regular intervals by the leading hydrographic bureaus.

The gradual improvement in understanding was integrated from the researches of many investigators. In *Untersuchungen über den Magnetismus der Erde,* Christopher Hansteen published, in 1819, a history of magnetic observations up to about 1800 with tables of results to 1819. This work was accompanied by a magnetic atlas showing changes in geomagnetism since 1600.

Perhaps the greatest fundamental advance since Gilbert's theory was that resulting from the investigations of C. F. Gauss and his colleague, W. Weber. Gauss developed the technique to determine the intensity of the geomagnetic field, published in 1832, in a system of absolute units involving length, mass, and time. The unit of this so-called centimeter-gram-second (C.G.S.) system is designated as the gauss (Γ); for convenience, a smaller unit is used and designated gamma (γ), equal to 0.00001 gauss.

## THE GEOMAGNETIC FIELD AND SURVEYS

**Main Field.** The earth's magnetic field extends far out into space, falling off inversely as the cube of distance; for example, 4,000 mi. above the earth it is one-eighth as great as at the surface. Upper-air observations of the geomagnetic elements, as well as below the surface of land and sea, are needed, because the regular and irregular changes may undergo considerable modification with change in altitude. Developments in instrumental technique during World War II have made feasible extensive and accurate surveys by aircraft.

The analyses of geomagnetic world surveys on the surface indicate the value of the earth's magnetic moment, $M$, to be $8 \times 10^{25}$ C.G.S. units, of which about 95 per cent is attributable to forces beneath the surface of the earth. The remainder, in one minor portion, is attributable to forces above the earth, and, in another, to currents passing through its crust. From

about 1847 to 1950 the intensity of this field apparently decreased at an annual rate of one fifteen-hundreth part, the average value for corresponding parallels north and south being generally larger for land-predominating, than for ocean-predominating, parallels.

**Magnetic and Geomagnetic Poles.** This magnetization is not uniformly distributed. The distribution of magnetic ore deposits and the superposition of their resulting local fields make the actually observed field a composite one. The so-called magnetic poles of this composite field are distant a thousand miles or more from the geographic poles, with the north magnetic pole approximately in 73° N. lat. and 100° W. long., the south magnetic pole in 68° S. lat. and 144° E. long. These two poles are not diametrically opposite, since the line joining them passes about 700 miles away from the center of the earth. Consideration of observations at or in the region of these poles, and of isomagnetic charts for various epochs, has raised the question of possible shifts of the poles over long periods of time.

**Magnetic Anomalies.** Irregularities of distribution of the geomagnetic field over continental areas may bear definite relation to geologic features of the earth's crust. Though these irregularities have long been recognized, it is only comparatively recently that they have been intensively considered as an aid in the study of geologic substructure. The random distribution of magnetic ore deposits in the crust of the earth produces so-called magnetic anomalies. Some of these are quite small and intense, with magnetic effects limited to a few square miles; for example, near Juneau, Alaska, where in a small area the declination is reversed. Others, like those in the U.S.S.R. at Kursk, in Germany at Berggiesshübel, and in southern Transvaal at the Pilansberg dike system, cause irregularities of magnetic intensity twice or even three times the normal value. At Pilansberg in 1938, fourteen vertical dikes were found to be strongly magnetized in a direction opposite to the normal geomagnetic field. Such anomalies must have counterparts in the great oceanic basins. Observations in isolated islands and island groups almost invariably indicate abnormal magnetic conditions.

**Magnetic Surveys and Charts.** The delineation of the geomagnetic field is determined by magnetic surveys. Measurements to determine that field at any point must include observations of the three elements: (1) magnetic declination ($D$), the angle between the true astronomic north-south meridional plane and the vertical plane through the magnetic north-south direction, as defined by the compass; (2) magnetic inclination or dip ($I$), the angle through which a magnet wholly free to move would dip below the horizon in the magnetic north-south meridional plane; and (3) the total magnetic force ($F$), acting in the magnetic meridional plane, or the horizontal ($H$) or vertical ($Z$) component of that force.

The values of $D$ are determined by observing (a) the direction, on a horizontal circle graduated in arc, taken by a magnet free to turn about a vertical axis, and (b) the true astronomic direction on the same circle through observations of the sun or on a star. These observations may be made with an ordinary pivoted compass or by a magnetometer and astronomic telescope (both mounted in the same alidade) in which the magnet is suspended by an extremely fine fiber of silk, bronze, or quartz. A dip circle or an earth inductor is used to determine $I$. The dip circle is essentially a magnetic needle mounted so that it is free to turn about a horizontal axis. An earth inductor, which is more precise, is essentially a closed coil of wire that is rotated in the earth's field about an axis in the plane of the coil; when rotated, an electric current is induced in the windings of the coil, except that when the rotating axis is orientated in the magnetic north-south meridional plane in the direction of $F$ no current is induced. The intensity ($H$) is usually determined through measurement of the angle of deflection of an auxiliary freely suspended magnet in a magnetometer by another magnet mounted perpendicularly to it. Electromagnetic instruments, depending on measurements of electric currents induced in rotating coils of wire in the earth's field, give more accurate values of $F$, $H$, or $I$ and have come into more general use since about 1930.

The motion of a surface vessel or an aircraft makes observations at sea or in the air more difficult. Gimbal suspensions are used, and until about 1920 instruments for oceanic surveys were of the magnetic type in principle but with appropriate modifications from those used on land. The development of electromagnetic instruments since that time has made more accurate determinations possible both at sea and in the air.

Following partial and scattered surveys on land in earlier times, and those of Halley at sea, many surveys over the continents and oceans were made by various governments. These culminated in the first general world magnetic survey of the Department of Terrestrial Magnetism of the Carnegie Institution of Washington, through some 150 expeditions in magnetically unexplored regions, between 1905 and 1940, and in cruises of the brigantine *Galilee* and of the specially constructed non-magnetic yacht *Carnegie,* between 1905 and 1920, over nearly 350,000 nautical miles in all oceans between 80° N. lat and 60° S. lat. Instruments of latest types were used, and the data obtained were of greater accuracy than any previously determined. The latest published isomagnetic charts are based upon an extensive discussion and analysis of this survey and of data obtained at established world-wide magnetic observatories.

**Magnetic Observatories.** In view of the regular and irregular variations of the earth's magnetic field, the data obtained at fixed magnetic observatories are essential in the world magnetic survey and investigations. Early in the nineteenth century, under the stimulus of the theoretical studies of Gauss and his colleagues and predecessors, the first observatories continuously recording the changes in the geomagnetic elements were set up. In 1947, there were some 70 established observatories. The polar regions, though including only one-seventh of the earth's surface, are unique because of the proximity of the poles and because of the great changes in the magnetic field there in short distances and short intervals of time.

## CHANGES OF GEOMAGNETIC FIELD— REGULAR AND IRREGULAR

**Secular Variation and Isoporic Charts.** The comparison for different epochs of isomagnetic charts, or of results at a single station, shows slow changes taking place in all geomagnetic elements. The importance in practical use of the magnetic compass is evidenced by actual observations made at London. There, the magnetic needle pointed 11° east of north in 1580, gradually changed to 24° west of north in 1812, and then shifted until it was 10° west of north in 1947. Secular-variation data at stations in other parts of the world show different periods and amplitudes; hence the popular explanation that such changes result wholly or mainly by shift in position of the geomagnetic axis, or poles, of the earth must be dismissed as insufficient.

On assembly of data, the shifts of isomagnetic lines are determined for successive years. An isoporic chart is one

showing lines along which the isomagnetics make the same annual progress. That changes are still taking place within the earth is indicated by these varying isopors, by the slow expansion and then gradual retraction of the areas in which there have been large alterations in any of the elements, and by the irregular drift in position with the years of the foci of maximum and minimum.

Since about 1939, investigators have sought to extend knowledge of secular variation, over a longer time scale than is available from recorded observations, through paleomagnetic research. This is the determination of what may be called "fossil magnetization" of cores of material collected at the bottoms of the oceans and of varves (layers of silt), deposited during the last Ice Age about 30,000 years ago. Work done on varves prior to World War II indicated that changes in declination and inclination varied similarly to those observed since early in the sixteenth century. A preliminary determination in 1946 of the intensity of magnetization of varves deposited in New England during the last Ice Age showed that the behavior of the magnetic intensity of the earth was unchanged for 30,000 years, within the accuracy of the measurement.

**Diurnal and Other Regular Variations.** The second important change with time in geomagnetism—the solar diurnal variation—was discovered by George Graham in 1722 at London. This is a 24-hour variation, progressing according to local mean time. It changes with season, having a greater amplitude in summer than in winter; is opposite in the Northern and Southern Hemispheres; is more pronounced near the poles; varies with the state of activity of the earth's field; and is modified in character with changes in the frequency of sunspots, that is, with the cycle of variation in solar activity.

There is also an annual, though generally small, cycle of variation, which should not be confused with the secular or annual change of mean values. Its cause appears to be outside the earth.

Another quite small but systematic variation is that associated with the moon's position, which was discovered by K. Kreil in 1850. It is related to the lunar day, which on the average is 50 min. longer than the solar day. Its magnitude is less than one-tenth that of the solar diurnal variation. It has a double wave during the lunar day of 24 hours and is the most conspicuous lunar effect on the earth apart from the oceanic tides.

**Irregular Variations and Magnetic Activity.** In addition to the progressive and regular variations of geomagnetism, there are irregular ones of many kinds which are generally classed as magnetic storms or perturbations. These frequently take place simultaneously, or nearly so, over the whole globe and are generally more pronounced in the regions about the poles. One form begins abruptly, with no preliminary indication, and is named "sudden commencement." Another of less irregular form, extending over 30 min. or more, is bay-like and therefore carries the designation "bay." There are storms of prolonged duration, sometimes over several days, the photographic records of which show innumerable irregular fluctuations before gradually returning to a normal state following a low-value period—somewhat like the behavior of a Leyden jar after discharge. Magnetic-storm periods are frequently accompanied by greater or lesser displays of polar lights and irregular changes in the natural electric currents flowing in the earth; they wax and wane with the number and size of sunspots or other evidence of solar activity.

These quasi-regular and irregular conditions are measures of the earth's magnetic activity, that is, its general state of magnetic rest or unrest. There are several ways to define geomagnetic activity quantitatively. The simplest, adopted in 1906, is the daily international magnetic character figure. Each observatory, from inspection of a day's records, assigns to each 24 hours between successive Greenwich midnights a character figure on a scale of 0, 1, and 2. A quiet magnetic day is rated 0, a moderately disturbed day 1, and a greatly disturbed day 2. The adopted daily values ($C$), to the nearest 0.1, are the averages as assigned at various observatories. The use of mean values of $C$ from 40 to 50 world-wide observatories established correlations between geomagnetic activity and other geophysical phenomena. One example is the tendency to a 27-day recurrence in magnetic storms and relation to rotation of disturbed regions of the sun, designated as $M$ regions.

Two other somewhat more objective measures of geomagnetic activity are the so-called $u$ measure and the 3-hour-range index ($K$). The former depends on the average difference, regardless of sign, in the force directing the compass between successive daily means. The latter was introduced internationally about 1939 to meet the need of a homogeneous running record of solar corpuscular radiation, by measuring the intensity of geomagnetic activity resulting from electric currents produced around the earth by that radiation. Intrinsically, $K$ is a measure for eight 3-hour intervals for each Greenwich-mean-time day from 0 to 24 hours, on a scale of 0 to 9 for the difference on normal records at each observatory. Values of $K$ are quite useful in determining correlations with phenomena in the high atmosphere.

## COSMIC RELATIONS

**Solar Relations.** Observations of variations in the activity of sunspots and of the earth's magnetic field over more than a century, at stations in Europe and North America, show close parallelism from year to year during a solar 11-year cycle. As the earth revolves around the sun during the year, there are geomagnetic fluctuations with maxima during the equinoctial months of March and September and minima during the solstitial months of June and December.

**Polar-Light Relation.** Minute electrified particles or corpuscles coming continually from the sun are entrapped by the geomagnetic lines of force reaching far into space. They are made to travel spirally around those lines where the lines are steepest—in the regions above the poles—and become luminescent because of the atmosphere's resistance as they penetrate deeper. As a result, there are polar lights, visible most frequently in the polar zones but sometimes, during great magnetic storms, visible in the temperate and even the torrid zones. Photographs of auroras made simultaneously from two stations at a measured distance apart show that polar-light beams generally do not come closer to the earth's surface than about 60 miles; some are observed to heights of 300 miles or more.

**Ionospheric Relation.** A hypothesis, based on geomagnetic data, on the existence of an electrified outer atmosphere —the ionosphere—was made about 1882 by Balfour Stewart. Gauss in 1838 had forecast this as a possible result of future study of the regular diurnal and irregular changes of the geomagnetic field. Stewart concluded from a discussion of the diurnal magnetic varations that they originate in the upper atmospheric layers and that these layers must conduct electricity much better than the almost nonconducting air near the earth's surface. The mathematical verification of these basic ideas, indicating ultraviolet radiation as the ionizer or electrifying agent, was made by A. Schuster about 1889.

E. V. Appleton and M. A. F. Barnett of England and G. Breit and M. A. Tuve of the United States observed directly

in 1925, by radio pulse waves, the ionized layers of the outer atmosphere. Instrumental technique was soon thereafter developed by which continuous automatic photographic records could be made of the electrification of the three ionospheric regions. These regions are known technically as the *E* region at about an average of 60 miles above the earth's surface, the *F*1 region at about 130 miles, and the *F*2 region at about 185 miles. From such data was developed the magneto-ionic theory, which has been completely confirmed experimentally. This theory provides for exact measurement of electron densities at various levels, including atmospheric regions far from the earth, by the use of radio waves. The geomagnetic field was essential in this development.

As was first pointed out by J. H. Dellinger in 1935, radio fade-outs or blackouts frequently coincide with bright eruptions or flares in the solar chromosphere and with geomagnetic changes of unique character associated with an increase of diurnal variation. Actual photographic records of a fade-out and simultaneous characteristic geomagnetic and solar-flare effects, first obtained in 1937, made the physical relationship conspicuously certain.

**Cosmic-Ray Relations.** Active research on penetrating radiation—cosmic rays—began with the work of J. Elster and H. Geitel and of C. T. R. Wilson in 1900 and 1901. Wilson showed that enclosed dry air is not a perfect electrical insulator and has a weak conductivity. Investigations of available cosmic-ray data by A. Göckel in 1911 and by V. F. Hess and others shortly afterward proved that cosmic-ray intensity increases with altitude, indicating origin outside the earth rather than inside it, as previously thought.

## TERRESTRIAL ELECTRICITY

Terrestrial electricity, or geoelectricity, has to do with those natural electric phenomena which occur within the earth—earth currents—and those which are found in the atmosphere of the earth—atmospheric electricity.

Natural earth currents were originally measured by W. H. Barlow in 1847, although Sir Humphry Davy suggested them in 1821 and M. Faraday, though unsuccessful in attempts to observe them, was confident that they existed. These currents circulate in the crust of the earth and are generally weak, but in times of disturbances they may attain strength sufficient to interfere seriously with telegraphic transmission. These currents and the atmospheric-electric phenomena may be grouped as the electric field of the earth and its atmosphere.

**Earth Currents.** It is found that earth currents constitute a world-wide system which differs from place to place, and which is subject to regular and periodic and to irregular variations, both in intensity and direction. The regular variations and disturbances show constant relationships to changes noted in other cosmic phenomena; for example, to those noted in the earth's magnetic field during displays of the aurora and during solar disturbances. The earlier attempts to measure earth currents were often contradictory, because some natural currents are purely local in character, and artificial currents like those due to leakage from power-systems are superimposed.

There is a physical connection between earth currents and the geomagnetic field, though the relation has yet to be determined. Even though earth currents may be directly produced by magnetic changes, they should have a reaction that would affect the measured variations of magnetic force with a strength of reaction depending on the internal structure of the earth. Thus, it is apparent that a simple relationship can hardly be expected. Records of diurnal variations on calm and disturbed days, from observations at Watheroo (Western Australia), Ebro (Spain), Huancayo (Peru), and Tucson (Ariz.), show small definite and distinctive differences in the magnetic variations during periods of disturbed earth currents. Seasonal changes in normal earth-current activity are quite similar to those in magnetic variations. It is safe to say that no explanation of magnetic variations can be accepted unless it suffices for earth currents.

Gradients of earth-current potential of as much as several volts per kilometer have been observed. World-wide storms, characterized by sudden commencements which occur simultaneously at widely separated stations, coincide with similar magnetic storms. The 27-day recurrence in disturbances was shown by W. J. Peters and C. E. Ennis to be a feature of earth currents, as well as of geomagnetism.

Discussions by O. H. Gish of the available data show the existence of a system of eight current whorls symmetrically spaced as regards the equator, and a secondary series of similar whorls near the North Pole. On the daylight side of the earth, the whorls are large and well defined, whereas those on the dark side are less definite. These current whorls may be considered as fixed in space under the sun, with any point on the earth occupying successive positions in them as the earth rotates. Consideration of a diagram of these whorls shows the significance of the commonly noted features of diurnal variations at middle-latitude stations generally in a longitudinal direction of current flow, the surge of current toward the equator near noon, and reversal of direction during the forenoon and afternoon.

**Atmospheric Electricity.** The classical kite experiments on the electrification of clouds and the nature of lightning by Benjamin Franklin in 1752 furnished the foundation for atmospheric electric investigations. Franklin's observations approximately coincided with those of P. C. Lemonnier in France, who showed that even under cloud-free conditions the atmosphere is the seat of an appreciable electric field. The development of the study of the electric phenomena of the atmosphere advanced somewhat after the introduction of the quadrant electrometer by Lord Kelvin, and following the work of F. Exner. Greater study and development began after the introduction by J. J. Thomson of the ionic theory of the electrical conduction in gases, and under the leadership of J. Elster and H. Geitel the foundations were laid for present-day investigations of the electric field. These investigations took on greater importance after 1900 because of bearings on recent theories of electricity and because of their intimate association and correlations with geomagnetic phenomena, with which strong parallelism as regards space and time distribution and variations was found. The range and perturbations of electric diurnal variations are much greater than those for magnetic elements, and more dependent on meteorological conditions, but the change of absolute values with geographic position is not so great.

In general, the atmospheric-electric phenomena observed include potential gradient, conductivity, and ionization. On clear days the earth is negatively charged with respect to the air, and in the lower layers of the atmosphere the difference in potential between the earth and a point in the atmosphere increases with its height above the earth. The change in potential per meter is defined as potential gradient; under good meteorological conditions, its average value determined at many stations on land and sea is on the order of 130 volts per meter at sea level; that is, the potential of the air one meter above the ground is 130 volts higher than the potential of the ground. Observation shows that, in general, the gradient decreases with land altitude; for example, its value at the Huancayo magnetic observatory, at 11,000 ft. above sea level,

is about 50 volts per meter. On the other hand, the conductivity increases with altitude. Fair-weather values of the negative and positive conductivities of the lower atmosphere are of the order of $10^{-4}$ electrostatic unit (e.s.u.), the positive conductivity being in general 10 to 20 per cent larger than the negative conductivity. Observations of ionic content indicate average values ranging from 500 to 1,000 ions (of either sign) per cubic centimeter, the number of positive ions being about 20 per cent greater, thus leaving a volume charge in the atmosphere amounting to several hundred free positive ions per cubic centimeter. Values of the air-earth current density, from simultaneous observations of potential gradient and conductivity, are of the order of $10^{-6}$ e.s.u., the value being somewhat greater over land than over sea.

From discussions and analysis of the atmospheric-electric observation at sea on the *Carnegie* from 1915 to 1921, S. J. Mauchly found that the chief component of the diurnal variation of the potential gradient is a 24-hour wave occurring simultaneously in the same phase in all localities. It was found from consideration of observations on land that, in general, this 24-hour wave progresses also approximately according to universal time over the entire land surface of the earth. The greatest value of the gradient occurs at an average during the year between $17^h$ and $19^h$ universal time, which is approximately the time when the sun is in the meridian of the north magnetic pole of the earth. Possibly this fact indicates a close relationship between the magnetic and electric fields; thus far, the character of this relationship is unexplained. On the Arctic Drift expedition of Roald Amundsen during the three winters from 1922 to 1925, H. U. Sverdrup made a series of observations that confirmed this fundamental deduction. The data obtained for density of air-earth current from simultaneous potential-gradient and conductivity results at sea show also that atmospheric-electric phenomena can not be interpreted wholly on the basis of local conditions, however characteristic such features may be.

There is some evidence that the annual variation of atmospheric potential gradient progresses according to time of year rather than according to local seasons, which is significant from the viewpoint of solar relationship; the maxima of activity also occur near the equinoctial months, March and September, and the minima of activity near the solstitial months of June and September, corresponding as well to the fluctuations in earth-current activity and in the frequency of the northern lights. The gradual increase of the potential from the equator to 60° N. lat. and 60° S. lat. again suggests the world-wide predominance of the chief features of this element.

The conductivity and the potential gradient set up an electric conduction current. The value of this current, as derived from measurements, shows an average density $11 \times 10^{-7}$ e.s.u. per square centimeter, or $3.7 \times 10^{-6}$ amp. per square centimeter, and flows from air to earth except on rare occasions. For the whole earth, this would amount to a total current of 1,800 amp. The observations that provide a measure of the conduction-current density show that negative electricity is supplied to the earth and that positive electricity is supplied to the higher strata of the atmosphere by a process which neither increases nor decreases through many years, but which may fluctuate from year to year and from season to season, and which varies in a fairly regular manner during the day. It is estimated that thunderstorms in progress at any time on the whole earth give $2 \times 10^9$ kw. of power, whereas the power required to maintain the total fair-weather conduction current of about 1,800 amp. between the high strata of the atmosphere and the earth is about $6 \times 10^5$ kw. Thunderstorms occur most frequently at about the time of the Greenwich day when the atmosphere's potential gradient is greatest. This relation is the only basis of any theory that may account for the maintenance of the electric charge of the earth, despite the constant current of the air from the surface.

### THEORIES ON ORIGIN OF TERRESTRIAL MAGNETISM AND ELECTRICITY

The magnetic field of the earth is delineated and known with some accuracy. The origin and nature of its short-time variations are well understood, and many can be predicted reasonably well. The cause of the main part—some 95 per cent or more—of the large magnetic moment of the earth is still unknown. The cause maintaining the earth's electric charge, despite the constant current of thousands of amperes from the air to the surface, is the second large outstanding problem.

The connecting link, if any, between the geomagnetic and the atmospheric-electric phenomena is very loose. The latter depend largely, at any one region, on local circumstances of topography, of meteorology, and of climatology. Terrestrial magnetism, though connected in some degree with geologic structure, is found to be largely independent of local conditions. The fundamental difference is that the chief variations of atmospheric electricity originate in the lower 12 to 15 miles of the atmosphere, whereas those in terrestrial magnetism are produced by electric phenomena in the ionosphere at 60 to 185 miles—a region most greatly affected by solar and cosmic influences.

Theories as to magnetic diurnal variation satisfactorily ascribe the internal part of the variation field to currents induced within the earth. Most theories concerning magnetic perturbations attribute them to the action of corpuscular radiations from the sun and induction of currents by dyamo action, as outlined by S. Chapman in 1918.

In 1947, P. M. S. Blackett revived the earlier ideas of W. Sutherland and A. Schuster that the magnetic moment ($P$) and angular momentum ($U$) of massive bodies are nearly proportional to the square root of the gravitational constant ($G$) divided by the velocity of light ($c$). This revival followed H. D. Babcock's spectrographic determination in 1947 of the magnetic field of the rapidly rotating star 78 Virginis. From this result, and from the magnetic field of the sun determined, in 1913, by G. E. Hale, Brackett expresses the relation:

$$P = \beta(G/c)U,$$

where $\beta$ is a constant of the order of unity. The polar magnetic fields are 0.6, 53, and 1,500 Gauss for the earth, the sun, and 78 Virginis, respectively.

The hypothesis that any body becomes magnetic on rotation was tested experimentally in the laboratory by S. J. Barnett, who concluded, in 1933, that a sphere rotating in a nonmagnetic field does become magnetic but in far too small a degree to account for either the earth's main field or that of the sun. The observed relation expressed in the above formula for the magnetic fields of three massive rotating bodies focuses attention on the possibility that the geomagnetic field does arise because of the greatness and rotation of the earth. *See also* AURORA BOREALIS AND AURORA AUSTRALIS; COSMIC RAYS; ELECTRICITY AND MAGNETISM; MAGNET; METEOROLOGY; SOLAR SYSTEM.

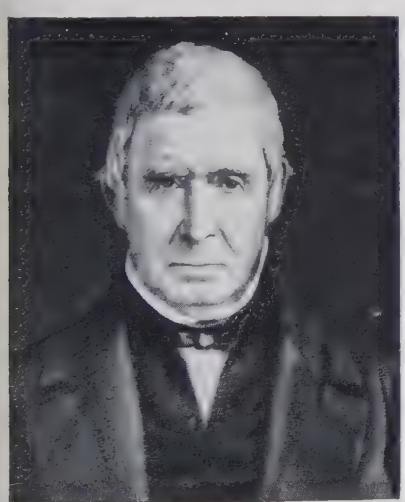
**TERRIER.** *See* DOG.

**TERROR, MOUNT,** an extinct volcano on Ross Island, at 77° 30′ S. lat. and 168° 40′ E. long. This mountain,

10,750 ft. high, and near-by Mount Erebus (13,200 ft.), an active volcano, were named after the two ships, *Terror* and *Erebus,* of the expedition (1839-1843) commanded by James Clark Ross when he discovered the Ross Sea entrance to the Antarctic Continent. Mount Terror, visible above the outermost edge of the Ross Shelf Ice, has been used as a landmark for ships sailing the Ross Sea west of Ross Island.

H. J. W.

**TERRY,** the name of a family of American clockmakers, of whom the most noted were Eli Terry (1772-1852) and his son, Silas Burnham Terry (1807-1876). Eli Terry was born in East Windsor, Conn., Apr. 13, 1772. After serving an apprenticeship under Daniel Burnap, the clockmaker, Terry established himself in East Windsor in 1792. Here he produced his first clocks, utilizing both brass and wood movements. He moved to Northbury (now Plymouth), Conn., in 1793, and in 1797 received a United States patent on an "equation" clock. Terry evolved the idea of mass-producing clocks and by 1800 was making wooden movements in quantity by cutting parts with water-powered saws. He perfected his manufacturing techniques and in 1808 turned out 4,000 wooden-movement wall clocks for a Waterbury firm. In 1814 Terry received a patent on the original form of his famous "Pillar and Scroll" shelf clock; a later version of this design sold in the thousands, bringing him wealth and fame. He retired from active business in 1834 and devoted the rest of his life to research and development in the field of clock movements. Terry was granted nine United States patents for his various horological inventions. He died in Terryville, Conn., Feb. 24, 1852. He was the father of eleven children,



*ELI TERRY*

BROWN BROTHERS

three of whom, Eli, Henry, and Silas, were also prominent clockmakers.

Silas Burnham Terry (1807-1876) was born in Plymouth, Conn., Feb. 1, 1807. He learned the fundamentals of clockmaking from his father and by 1824 had established his own clock factory. Unlike his father, he did little work in wood, preferring to mass-produce brass-movement clocks. Most American clocks of that period were powered by a controlled fall of weights, but in November 1830 Silas Terry received a United States patent on a coiled-spring power unit. He also invented clock-making machinery. His inventions and improvements did much to benefit American clockmaking. Silas Terry died in Winsted, Conn., May 20, 1876. B. P.

**TERRY, ELLEN ALICIA** or **ALICE** (1847-1928), English actress, was born in Coventry on Feb. 27, 1847. Brought up by parents active in the theatre, she made her stage debut in London in 1856 and soon became a great favorite. She joined Henry Irving in 1867, starring for many years in his elaborate productions at the London Lyceum, and touring the United States with him. Her favorite roles were the heroines of Shakespeare. She had three husbands: George Frederick Watts, the painter; Charles Claverine Wardell, an

*ELLEN TERRY*

CULVER SERVICE

actor known professionally as Charles Kelly; and James Carew, an American actor. Ellen Terry was the mother of Edith Craig, a writer, and Edward Gordon Craig, who became world-famous as a stage designer. Among her many friends was George Bernard Shaw, with whom she corresponded at length. After Irving's death in 1905, Ellen Terry acted under various managements. In her long career she appeared in many roles, in plays by Reade, Tennyson, Wills, and Sardou, but it is as Shakespeare's Portia that she is best remembered. England celebrated her golden jubilee at the Drury Lane in 1906, and in 1925 George V made her Dame Grand Cross of the British Empire. She died July 21, 1928, at Small Hythe, Kent.

**TERTULLIAN (QUINTUS SEPTIMIUS FLORENS TERTULLIANUS)** [tɛrtʌ'lyən] (c.155-c.245), early Christian theologian, the son of a centurion, was born at Carthage before 160. After a thorough rhetorical and legal education he successfully practiced law at Rome. Converted to Christianity at an unknown date, he returned about 195 to Carthage, where he was ordained priest, probably about 200, and lived, in the words of St. Jerome, "to a decrepit age."

While Tertullian was a scholar widely read in Scripture and the Greek authors, his thirty-one extant works are largely practical and devoted to the relations of Christians to paganism, the conduct of Christians, and the refutation of heretics. Fourteen of his works are known to be lost. In his first or Roman Catholic period he refuted accusations against the Christians in *Ad nationes* (197) and *Apologeticus;* exhorted Christians in *De spectaculis, De idololatria, De cultu feminarum* and *Ad uxorem;* instructed catechumens in *De baptismo, De oratione, De poenitentia;* and denied heretics a hearing in *De praescriptione haereticorum* (c. 200). Increased rigorism marked his writings as he moved toward Montanism. The five books *Contra Mar-*

*cionem* (final edition c. 211) contain valuable information on Marcion's gnosticism, while *De anima* (probably c. 211) is the first Christian treatise on the soul. After his formal adherence to the Montanist sect (c. 212), he accused the Catholics ("Psychici") of laxity, and abounded in severity in *De fuga in persecutione* (c. 212), *De monogamia, De ieiunio* and *De pudicitia,* a protest against the Church's pardoning of adulterers and fornicators after due penance. *De pudicitia,* perhaps his last work, was occasioned by a decree of Callistus I, who was pope from 221 to 227. Eventually he founded the Tertullionists; it is virtually certain that he never returned to the Roman Church.

Tertullian's character was intensely individualistic, impetuous, uncompromising, militant; his argumentation keen, original, eloquent, if sometimes sophistic and ungracious; his style concise, clever, vigorous, often tortuous and obscure, abounding in pointed antitheses. He was long neglected, but much studied by the Humanists. In Tertullian, called the "hard African" by Bossuet, and "the Master" by St. Cyprian, modern scholars have seen the first Latin Christian writer, the inventor of a needed terminology, and the founder of Western theology. N. J. T.

**TERUEL** [terwɛ'l], capital of the province of the same name in Aragon, east central Spain.

**The City.** The city of Teruel rests on a hill overlooking the Guadalaviar or Turia River from the east, at the point where the Alfambra flows into it. The altitude is over 3,000 ft. above sea level, and the climate is marked by cool winters and an annual rainfall of around 15 in. Teruel is almost devoid of industry, depending instead on its trade with the surrounding area and its position as an administrative center.

*A street in Teruel, with the crowded buildings typical of the old city*

COURTESY OF THE SPANISH TOURIST OFFICE

The city has grown very little during the last century, and the older part of town is still enclosed within medieval walls. Pop. 1947, 18,112.

**The Province.** The province of Teruel, the southernmost in Aragon, has an area of 5,721 sq. mi. It is bounded on the west by New Castile and on the south and east by Valencia. In general the terrain is rugged, except at the northeast in the lower Ebro Plain. There are a number of sierras: San Just, Gudar, and Palomera in the middle; Albarracín in the west; and Javalambre in the south, where elevations exceed 6,000 ft. The principal rivers flowing northward into the Ebro are the Jiloca, Martín and Guadalope. The Guadalaviar is the chief stream in the south. Because of the accidented topography and the scanty rainfall, the main agricultural pursuit of the province is extensive cereal culture. Olive trees abound, wine is produced, and livestock (chiefly sheep) are pastured. Iron ore and lignite are mined. Pop. 1947, 219,518. R. G. W.

**TERYLENE.** *See* SYNTHETIC FIBERS.

**TERZA RIMA** [tɛ'rtsɑ ri'mɑ], an Italian verse form, used by Dante for the *Divine Comedy,* composed of three-line stanzas of iambic pentameter in which the middle line of each rhymes with the first and third of the following, thus: *aba, bcb, cdc.* Normally, the final stanza of each poem or each major section of the poem is a quatrain, in which the fourth line repeats the rhyme of the second line. Numerous poets have used the form in other languages. Introduced into English by Sir Thomas Wyatt, it has been used only infrequently, and best, perhaps, in Percy Bysshe Shelley's *Ode to the West Wind,* where the traditional final quatrain is changed to a couplet. In the twentieth century, Archibald MacLeish employed effectively a modified terza rima for his epic poem, *Conquistador,* in which five-stress lines are linked with assonance instead of with rhyme. R. Bn.

**TESHE LUMPO.** *See* SHIGATSE.

**TESSITURA** [tɛ'ssitu'rɑ], a term in music for the general pitch-range or "lie" of a vocal or instrumental part, disregarding isolated upper or lower extremes. The range or compass of an aria, for example, extends from its lowest to its highest note; its tessitura includes only that portion of the range frequently used. The midpoint of a tessitura is thus a center of gravity or an average, while that of a range is a geometrical center or mean. W. Li.

**TESS OF THE D'URBERVILLES** [dɜ'rbərvɪlz], a novel by Thomas Hardy, first published in 1891, at once becoming enormously popular.

A humble Dorsetshire dairymaid, Tess Durbeyfield, a descendant of the ancient D'Urberville family, is encouraged by her drunken father and her shiftless mother to aim at a "good" marriage with a wealthy young squire, Alec D'Urberville, who heartlessly seduces and deserts her. After the birth and death of her baby, Tess finds employment on a dairy farm, where Angel Clare, the son of a gentleman, falls in love with her. Chance frustrates Tess's attempt to tell Clare about her past, and they are married; when Tess eventually discloses her history to her husband, he leaves her, resigning her and her poverty-stricken family to every misfortune. In her despair Tess accepts help, at a price, from the man who had first seduced her. When her husband returns from Brazil, where he had fled, Tess feels that Alec has again wrecked her life, and in a frenzy she stabs him to death. After a few ecstatic days

of reconciliation with her husband, she is arrested, tried, convicted, and executed. " 'Justice' was done," Hardy bitterly remarks as the novel closes. C. J. W.

**TESTES** [tɛ′stiz], or male gonads, glands located in the scrotal sacs of most mammalian species. They arise in the abdominal cavity and generally descend to their scrotal position just before or shortly after birth. If a testis is retained in the abdominal cavity for a long period the gland is permanently sterilized by the increased temperature. The hormone production of undescended testes is maintained for long periods but may eventually decline.

A testis is composed of coiled, seminiferous tubules in which the sperm cells develop. Around the seminiferous tubules is the interstitial tissue, which secretes at least one substance, thought to be testosterone, having male hormone activity. This male hormone maintains the reproductive tract of the male in functional condition, and the sex organs fail to attain adult size in its absence. In addition, it causes development of the male secondary sex characteristics. *See also* MAN, FUNCTIONAL ANATOMY OF; REPRODUCTION, HUMAN. R. G.

**TESUQUE.** *See* INDIAN TRIBES, NORTH AMERICAN (*Southwest*).

**TETANUS** [tɛ′tənəs], also known as lockjaw or trismus, an acute and often fatal infectious disease characterized by tonic spasms of the voluntary muscles. It is one of the oldest known diseases and has been described by Hippocrates, whose son himself was a victim of tetanus. Tetanus was once recognized as one of the hazards of war, since it was the cause of death of a considerable percentage of the wounded.

**Cause.** Clinical manifestations of tetanus are due to a toxin produced by the growing spores of an anaerobic microorganism, *Clostridium tetani* (*Bacillus tetani*). This bacillus, found in the surface layers of the soil and in human and animal excreta, is particularly abundant in cultivated and manured fields, especially in the tropics. The vegetative forms are easily killed, but the spore-bearing forms of the bacillus are highly resistant to heat and chemicals. Ordinary boiling does not kill the spores; sun and air destroy them in about eighteen days.

The toxin produced by the tetanus bacillus is among the most potent water-soluble poisons known to man. It is carried by the bloodstream and thus reaches the ventral horn cells of the spinal cord. Infection is usually caused by contamination of wounds, burns, or lacerations with spore-bearing soil. Tetanus neonatorum (tetanus of the newborn), a highly fatal form, results from a contamination of the umbilicus. Cephalic tetanus, also a very severe form, develops from injuries about the head.

**Occurrence.** Tetanus is a world-wide disease, attacking virtually all warmblooded animals; mules and horses are among those most often affected. In man, tetanus may occur at all ages, although the greatest incidence is in boys under fifteen, in view of their greater exposure to traumatic injuries. Occupation may be a predisposing factor, as in the case of soldiers, farmers, and some industrial workers. In temperate zones, tetanus occurs more often in the warmer months, probably because of greater outdoor activity and less protective clothing.

**Symptoms.** The incubation period varies from three days to three weeks; the longer this period, the better the chance of recovery. In man, stiffness of the jaw is usually the first symptom. Restlessness, irritability, stiff neck, difficulty in swallowing, sore muscles, and an awkward gait may also be present. Later symptoms include rigidity of the neck and back muscles, difficulty in opening the jaws (trismus), profuse sweating, rigidity and contraction of the extremities, and the typical risus sardonicus—a painful, persistent grimace of the facial muscles which gives the impression of a sardonic grin. In severe cases, there is also opisthotonos—a convulsive, rigid, upward arching of the body. The mind remains clear and the temperature is often normal, but the mortality is high, exceeding 50 per cent, and is still greater in infants.

**Therapy and Prophylaxis.** Serum therapy is not always successful, since tetanus antitoxin exerts no immediate curative action, though it may help to arrest the advance of the disease. Prophylactic measures are of great importance. Passive immunization with antitetanus serum is indicated in the presence of injuries likely to have been contaminated with *C. tetani.* Since the period of passive immunity is short (seven to ten days), repeated injections are required until the wound heals. Active immunization with tetanus toxoid is conferred by several injections at intervals of three to four weeks; it is much more effective and lasting and has become routine in most armies. Children are protected by an active immunization with a tetanus-diphtheria toxoid. B. Van R.

**TETANY** [tɛ′təni], a disease complex characterized by intermittent tonic muscular spasms, especially of the hands and arms, and increased excitability of peripheral nerves.

**Causes and Occurrence.** Tetany is commonest between the ages of six months and two years. In its rare occurrence among adults it has been observed in certain digestive disorders; during pregnancy or lactation; following the inadvertent removal of the four parathyroid glands in a thyroidectomy; rarely in the course of an acute, infectious disease; in various intoxications; and after the ingestion of large doses of bicarbonate of soda (alkalosis). Experimentally it can be induced by forced respiration or overventilation of the lungs. In children there is apparently an association between tetany and rickets, both diseases having similar etiological features and occurring chiefly in the winter and spring. They are commoner among artificially fed than breast-fed infants, and are found chiefly among poorer classes. Blood calcium levels are different, however; in rickets a moderate diminution may be found, but in tetany the deficiency is marked.

**Symptoms and Treatment.** Tetanic symptoms are manifested as undue restlessness, irritability, excessive crying, and finally spasmodic phenomena, such as convulsions, carpopedal spasm, and laryngospasm. The convulsions are not unlike those of true epilepsy. Carpopedal spasm is the contraction of muscles of the hand and foot, causing these extremities to assume pathognomonic and diagnostic contractures which are frequently painful. These muscular spasms may be so intense that circulation is impeded, and hands and feet may become puffy and blue. Sometimes contracture of the lips occurs, producing the so-called "carp mouth." Laryngospasm is the most dangerous sign of tetany; at first, the child emits crowlike sounds and eventually the spasm may lead to complete closure of the larynx and respiratory block, causing death. Otherwise tetany is rarely fatal, and even without specific treatment the child usually outgrows the disease. Psychologically no mental deficiency or other impairment to the mind is elicited in the child who, as an infant, suffered tetany. Treatment during the acute phase consists in that of the underlying condition, which usually implies rickets, and of the attacks themselves. It

calls for diet regulation, breast milk, cod-liver oil, sunlight, ultraviolet radiation, and elimination of deleterious hygienic influences. Sedation, even anesthesia, for the convulsive and spasmodic attacks may be required. Calcium feedings are indicated. In chronic tetany modern therapy includes calcium feedings, vitamin $D_2$, and a synthetic compound known as dihydrotachysterol, which is irradiated ergosterol.

**TETE DE BOULE.** *See* INDIAN TRIBES, NORTH AMERICAN (*Western and Eastern Subarctic*).

**TETERNIKOV, FYODOR KUZMICH.** *See* SOLOGUB, FYODOR.

**TETHYS** [ti'thɪs], in Greek mythology, a Titaness, daughter of Uranus and Gaea and wife of Oceanus. She was the mother of innumerable river gods and ocean nymphs. *See also* TITANS.
G. E. D.

**TETON DAKOTA.** *See* INDIAN TRIBES, NORTH AMERICAN (*Plains*).

**TETRACHORD** [tɛ'trəkɔrd], the name applied by the ancient Greeks to a four-note scale bounded by an interval corresponding to our perfect fourth, as A-G-F-E. To form more extended scales, tetrachords were combined by conjunction, that is, by retaining a common note (A-G-F-E, E-D-C-B); or by disjunction, with no common note (A-G-F-E, D-C-B♭-A). When more than two tetrachords were combined, the resultant scales did not agree in different octaves unless conjunction and disjunction had been alternated. Today the term is applied to any four-tone scale segment.
J. M. Ba.

**TETRAHEDRITE** [tɛtrəhi'drait], an ore of copper and silver, is a sulphantimonide of copper, iron, zinc, and silver, $(Cu,Fe,Zn,Ag)_{12}Sb_4S_{13}$. Complete gradation exists between tetrahedrite and the sulpharsenide, tennantite. These minerals either crystallize in four-faced tetrahedrons or occur as formless masses. The color ranges from flint-gray to iron-black, but the streak is dark maroon. Tetrahedrite has no cleavage. It occurs in low- and especially in intermediate-temperature hydrothermal veins. Common associates are various lead and silver minerals. Tetrahedrite is an important ore mineral in the Idaho silver-lead district and is found in lesser amounts in mining districts in the Rocky Mountains and Mexico.

**TETRASACCHARIDES.** *See* SUGAR CHEMISTRY (*Oligosaccharides*).

**TETRAZZINI, LUISA** [te'trɑttsi'ni] (1871-1940), Italian coloratura soprano, was born June 28, 1871, in Florence. After a period of study she made her operatic debut in Florence in 1895 as Inez in *L'Africaine*. She then toured Italy and South America. In 1904, after singing in Mexico, she created a sensation in San Francisco, but she was not heard in New York until 1908, when she appeared at the Manhattan Opera House as Violetta in *La Traviata*. Thereafter most of her singing, in opera and also in concert, was done in America, her final appearance being in New York in 1931. Tetrazzini died Apr. 28, 1940, in Milan.
W. Li.

**TETSCHEN.** *See* DĚČÍN.

**TETUÁN** [tetwɑ'n], the capital of Spanish Morocco and the administrative center for the Spanish possessions in North Africa, hence the residence of the Spanish High Commissioner and of the Khalifa, the deputy of the Sherifian Sultan. Tetuán, located about 25 mi. south of Ceuta with which it is connected by road and rail, nestles among the hills on the Rio Martín, 6 mi. from the Mediterranean Sea. A port at the mouth of the river, from which pirates formerly operated, has now become badly silted, but the city maintains a port on the Mediterranean Sea. The climate is hot in summer but cool in winter, with considerable rainfall which exceeds 30 in. annually.

Originally the site of the Roman town of Tamuda, Tetuán seems not to have been important in medieval times. Early in the fourteenth century it was taken and devastated by Spanish forces. Rebuilt and populated by Moslems and Jews expelled from Andalucía in the fifteenth century, it became an industrial and commercial center. In 1859, during the brief African War waged by Spain against Morocco, Tetuán was captured by forces under General O'Donnell, who was later given the title of Duque de Tetuán. The city, however, was returned to the Sultan in 1862 and remained under his rule until 1913, when it was again occupied by Spanish troops, this time under the terms of the Franco-Spanish agreement of Nov. 27, 1912. Pop. 1950, 78,427.
R. G. W.

**TETZEL, JOHANN** [tɛ'tsəl] (1465-1519), German Dominican priest, was born in Pirna, in Saxony. His preaching on indulgences to aid the construction of St. Peter's brought odium upon him, which painstaking scholarship has but slowly removed. In 1518, in his 106 theses, he replied to Martin Luther's 95 theses on the subject of indulgences. Tetzel's doctrine on indulgences for the living was orthodox, but Cardinal Cajetan condemned his erroneous views on indulgences for the dead. Broken in health, he retired to the monastery at Leipzig, where he died, Aug. 11, 1519, receiving an honorable burial. Modern historians have cleared him of the charges of immorality that legend had levied against him.
W. C.

**TEUCER** [tyu'sər], in Greek mythology, the name of two legendary heroes. One, the son of the river-god Scamander and the nymph Idaea, was the first king of Troy. His daughter married Dardanus, and the Trojans were sometimes called Teucrians after him. Another Teucer was the son of Telamon and Hesione and the half-brother of Ajax; he was famed as an archer among the Greeks at Troy. Upon his return home after the war, Teucer was banished by his father because of his brother's death, and, going to Cyprus, he founded there a town which he named Salamis.
G. E. D.

**TEUFELSDRÖCKH, DIOGENES** [tɔi'fəlzdrök], fictitious German professor whose biography and writings were edited by Thomas Carlyle under the title *Sartor Resartus* ("The Tailor Retailored"). Teufelsdröckh, a prophetic mystic influenced by German Idealism, believed that, if society were to be revitalized, world thought, which had become clothed in materialistic expression, should be reclothed in spiritual terms.
N. MacM.

**TEUTONIC LANGUAGES.** *See* GERMANIC.

**TEUTONIC ORDER,** also known as the Order of the Knights of the Hospital of St. Mary of the Teutons in Jerusalem, a military and religious order which originated in Acre in 1190. A number of pilgrims from Lübeck and Bremen established a hospital at Acre which soon became affiliated with the German church of St. Mary in Jerusalem.

In 1198 the Germans who had gathered for Henry VI's crusade raised the brethren of the hospital to a military order of knighthood, open only to Germans. Until 1291 headquarters were maintained at Acre, then for a few years at Venice, while bitter feuds were carried on with the other crusading orders, the Knights Templar and the Hospitalers (Knights of St. John of Jerusalem). Early in the thirteenth century the Teutonic Knights turned their attention to Prussia. First established in Transylvania as a bulwark against the Cumans, the order was reorganized by Emperor Frederick II, and the work of Christianization and Germanization was instigated on the eastern frontier. The Emperor was a generous patron, who gave the grand master, Hermann of Salza, the status of a prince of the Empire.

In 1229 the Knights, under Hermann, answered an appeal for aid from the Duke of Poland and embarked on a crusade against the heathen Slavs of Prussia. The duke gave them lands and promised them whatever they should conquer from the Prussians. In 1234 they acknowledged their holdings as fiefs of the pope but exercised virtually sovereign rights, because only a strong pope was able to exert any influence over them. Three years later the order absorbed the Livonian Brothers of the Sword, and notable progress was made after the union. During the next hundred years they gained control over the whole Baltic coast from the Pomeranian border to the Gulf of Finland, carving out fiefs for the German barons, settling German peasants on the conquered lands, and, with the Hansa, building many new towns for German merchants. After 1309 the headquarters of the order was established at Marienburg in Prussia. After reaching the apex of its power, the order began to decline when its prosperity brought a relaxation of discipline. During the latter part of the fourteenth century, Polish power revived, especially after the union with Lithuania under Jagiello. In 1410 the Polish King Ladislas inflicted a crushing defeat on the Knights at the historic Battle of Tannenberg and in 1466 West Prussia passed to Poland, although the Knights continued to hold East Prussia as a fief of the Polish crown. In 1801 the Treaty of Lunéville absorbed their possessions on the left bank of the Rhine, and Napoleon in 1809 abandoned their territories on the right bank to his allies of the Confederation of the Rhine. The order survived only in Austria and in the ancient bailiwick of Utrecht, a Protestant branch that was re-established by William I of Orange. F. C. H.

**TEVERE.** *See* TIBER.

**TEWKESBURY** [tyu'ksbəri], a municipal borough in Gloucestershire, England, at the confluence of the Avon and Severn rivers, about 90 mi. northwest of London. Tewkesbury was granted its first charter in 1107 and was incorporated in 1574. The most interesting building in Tewkesbury is the abbey church, which was consecrated in 1125 and is one of the finest examples of early Norman architecture in England. Of particular interest are the great arched western front of the church and the 132-ft.-high Norman tower. Other noteworthy features of the church are the Founder's Chapel, the Beauchamp Chantry, the tomb of Hugh le Despenser III, and the tomb of the Duke of Clarence.

Tewkesbury was the scene of the last battle of the War of the Roses on May 3, 1471, when Edward IV crushed the last remnants of the Lancastrian forces, captured Queen Margaret, and killed Edward, Prince of Wales, the Lancastrian claimant to the throne. The Nortonbury of Mrs. Dinah Craik's novel *John Halifax, Gentleman* is patterned after Tewkesbury. Boots and shoes are the chief manufactures, but milling, carpentry, and the manufacture of aircraft parts are also important. Pop. 1952, 5,446. R. W. Cr.

**TEXARKANA** [tɛ'ksɑrkæ'nə], two contiguous cities of the same name in the adjoining states of Arkansas and Texas. One, the county seat of Miller Co., is in southwestern Arkansas; the other is in Bowie Co., northeastern Texas. Officially designated Texarkana, Arkansas-Texas, the twin cities form one commercial, industrial, and social unit, but both are set up under separate civic, county, and state governments.

The Texas & Pacific Railroad reached the site in 1873 and sold town lots that year. In 1874 the Cairo and Fulton Railroad in Arkansas met the Texas road there, and it in turn sold property for development on the Arkansas side. The community was named after Texas, Arkansas, and Louisiana, the latter being included because it was thought at that time that the state boundary was just a few miles distant. The Texas section was incorporated as a city in that state in 1874, and the other community was incorporated in 1880 in Arkansas.

Although each of the two sections of the city is governed separately by a mayor and city council, Texarkana is commercially one city, and there is joint operation of many of the local services. Abundant oil and gas deposits are found in the vicinity, as well as eighteen industrial minerals, including asphalt, lime, gypsum, clay, and iron. Cotton is the chief money crop of the region around Texarkana, with truck produce second. A rail and air junction, Texarkana has service supplied by the Mid-Continent and American air lines, and by the Missouri Pacific, Texas and Pacific, Kansas City Southern, and St. Louis Southwestern railroads. The strategic location of the twin cities in the border area of four states has aided their growth as a distribution and manufacturing center. The stockyards and horse and mule markets are important in the Southwest. The diversified factory output includes lumber, railroad cars and ties, furniture, cottonseed products, steel and metal products, creosote products, mattresses, and medicines. Pop. 1950, Texarkana, Ark., 15,875; Texarkana, Tex., 24,753. S. D. M.

**TEXAS,** one of the south central states of the United States. The name is derived from Tejas, the name which the Spaniards gave to the Hasinai Indians who lived in the east-

SEAL OF THE STATE OF TEXAS

ern portion of the state. Texas is known as the Lone Star State because the flag of the state, which also served the Republic of Texas, carries a single star. Texas is bounded on the south by Mexico and the Gulf of Mexico, on the east by

Louisiana and Arkansas, on the north by Arkansas and Oklahoma, and on the north and west by New Mexico. The state has an area of 263,644 sq. mi. of land and 3,695 sq. mi. of water for a total area of 267,339 sq. mi. It is the largest of the states. Texas is divided into 254 counties; the capital city is Austin.

Texas entered the Union Dec. 29, 1845, and became the twenty-eighth state. The state motto is "Friendship"; the state flower is the bluebonnet; the state bird is the mockingbird; the state tree is the pecan; and the state song is *Texas, Our Texas,* with music by William J. Marsh and words by Marsh and Gladys Yoakum Wright.

*EL PASO, TEXAS. BEYOND THIS WESTERN TEXAS CITY LIES CIUDAD JUÁREZ, MEXICO.*

SOUTHWEST PHOTO

## PHYSICAL FEATURES

**Topography.** The surface of Texas slopes upward from the Gulf Coast toward the north, northwest, and west, the altitude varying from sea level to plateaus of more than 4,000 ft. in the extreme northwestern and western sections. The surface is generally level to rolling except in the extreme west, which is crossed by the eastern ranges of the Rocky Mountains, the chief peaks being Guadalupe (8,751 feet), Livermore or Bald (8,382), and Emory (7,835). The northern part of the state drains into the Mississippi via the Red and the Canadian-Arkansas systems. The remainder of the state drains directly into the Gulf of Mexico, the chief rivers being the Rio Grande, which forms the international boundary line for 889 mi., the Nueces, the San Antonio, the Guadalupe, the Colorado, the Brazos, the Trinity, the Neches, and the Sabine. The Sabine River forms 180 mi. of the Texas-Louisiana border.

Physiographically, Texas is the meeting place of four great physical provinces: (1) the Gulf Coastal Plains, which extend into the state 200 mi. from the eastern boundary and thence along the coast to the Lower Rio Grande Valley; (2) the Lower Western Plains, which cover north central Texas, including the Blacklands, the Grand Prairie, and the rolling plains of west central Texas; (3) the Western High Plains, which cover most of the North Texas Panhandle and extend southward to the Rio Grande and eastward as far as San Antonio, being divided into the High Plains and the Edwards Plateau; (4) the Mountain Region, which covers most of the area west of the Pecos River, known locally as the Trans-Pecos.

The long coast line of Texas provides a number of harbors, of which the most important are at Galveston, Houston, Texas City, Beaumont, Port Arthur, Corpus Christi, and Port Aransas. Houston has become a port by virtue of a 50-mi. ship channel which connects the city with the Gulf of Mexico. A number of very long and narrow islands lie close off the Texas coast, forming extensive bays and lagoons, but only Galveston Island is economically important.

**Climate.** North to south, Texas extends from subtropical to middle temperate; east to west, from humid to arid. It has a range of 74° to 56° F. in mean annual temperature, which averages 66.3° F. Mean annual rainfall ranges from 8 in. to 56 in., with an average of 30.25 in. Maritime climatic conditions predominate on the coastal plains; mountain weather in the extreme west; and continental-type weather in the area lying between. The Lower Rio Grande Valley is practically frostless, while snow averages approximately 15 in. annually over the Panhandle.

Irregular rainfall and rapid runoff in the western part of the state create an alternate deluge and dearth of water. In the years since 1930 a number of large reservoirs have been constructed for water storage, flood control, irrigation, power, and other purposes. Among the largest of these are: Lake Texoma (United States Army) on the Red River, of 5,818,200 acre-feet capacity. Whitney Dam Lake (Brazos River Conservation District) on the Brazos, with a capacity of 2,017,000 acre-feet; Lake Travis (Lower Colorado River Authority) on the Colorado, with a capacity of 1,963,000 acre-feet; Lake Buchanan (Lower Colorado River Authority) on the Colorado, with a capacity of 992,475 acre-feet; and Possum Kingdom Lake (Brazos River Conservation District) on the Brazos, with a capacity of 750,000 acre-feet. When completed, the Falcon Reservoir (Rio Grande International Boundary Commission) will have a capacity of 3,300,000

acre-feet. The underground water resources of Texas are plentiful, although the water table is receding in some areas. More than half the cities of Texas, including Houston and San Antonio, derive their water supplies from underground sources. About half the water used for irrigation comes from underground sources.

**Soils.** According to Dr. W. T. Carter of the Texas Agricultural Experiment Station there are 130 soil series and about 500 soil types in Texas. The principal soil belts include: (1) heavy clays of the coastal prairie; (2) sandy and sandy clay lands of east Texas pine and post-oak belts; (3) black limestone-origin soils of the Blackland belt; (4) thinner gray limestone soils of the Grand Prairie and the Edwards Plateau; (5) red soils of Permian origin in north central and middle west Texas; (6) fine sandy and sandy loam soils of the High Plains; and (7) the rough, stony land of the Trans-Pecos and of some broken areas in the central and southwestern parts. Rolling terrain, erratic rainfall, careless cultivation, and overstocking of pasture lands have caused considerable erosion. Most of the state is now within soil conservation districts.

**Forests.** About half the area of Texas can be classed as forest, woodland, or brush land. The principal timber belts are as follows: (1) the east Texas pine belt, which is the western extension of the southern yellow pine region, covered with longleaf, shortleaf, and loblolly pine on the sandy uplands, and with hardwoods in the valleys, including gum, magnolia, cypress, elm, hickory, sycamore, and a variety of oaks (95 per cent of the state's 1950 lumber production of 1,500,000,000 board feet was from the pine belt); (2) the post-oak belt, which stretches across the state west of the pine belt; (3) the cross timbers of north central and central Texas, of post-oak, blackjack, and other hardwoods; (4) the mesquite lands covering south, central, middle west, and north central Texas; (5) the limited timber lands of the Trans-Pecos mountain region, including Douglas fir, ponderosa pine, and Pacific white pine in limited quantities; (6) the cedar breaks extending through south central, central, and north central Texas on the western fringe of the Grand Prairies; and (7) a wide area of borderland known as the Brush Country, covered with scrub oak and mesquite, huisache, huajillo, catclaw, and other shrubs, shrub-sized trees, and prickly pear cactus. The pecan grows along streams in the central and eastern portions of the state, producing a large commercial nut crop. Both state and national governments maintain extensive forest reserves, including a large variety of trees, in Texas.

**Flora.** Native grasses covering the Texas prairies and the lighter woodlands constitute possibly the state's greatest plant-life resource, though they are of indirect value. Because of their value to livestock they have been one of the principal factors in shaping the state's economy and cultural development. There are also more than four hundred varieties of wild flowers, of which the most notable families are the asters, daisies, goldenrod, and sunflower. Both species of the bluebonnet, *Lupinus texensis* and *Lupinus subcarnosus,* growing throughout central and south Texas, are accepted as the officially adopted state flower. Varieties of the primrose, gaillardia, phlox (notably Drummond's), and coreopsis are among the most common wild flowers. Flowering shrubs include the redbud, wild plum, huisache, catclaw, and huajillo, the last two producing a peculiarly fine flavor of honey. A variety of arid-land plants is found in the western part of the state, including the maguey, or century plant, the lechuguilla, the yucca, the sotol, and many varieties of cactus.

**Fauna.** The greatest game asset is the deer, principally the Virginia white-tailed deer, which is most abundant in the brush-covered country of southwest Texas. The State Game, Fish and Oyster Commission, which administers the game laws, estimates an annual deer kill of 35,000. Other wild game includes the Sonora and mule deer, antelope, and several varieties of squirrel. The coyote is the most numerous of the predators, and the gray wolf, timber wolf, and several varieties of the cat family are found, including the cougar, ocelot, jaguarundi, and bobcat. In 1946 the State Game Commission reported 150 to 300 mountain sheep in the Trans-Pecos Mountains. Notable in song and story are the javelina (Texas peccary) and the nine-banded armadillo. Principal fur-bearing animals are the opossum, skunk, ringtail, raccoon, fox, civet, and mink. The annual fur crop varies in value from $1,000,000 to $3,000,000.

Bird life is profuse, especially among the migratory species that seasonally fly the continental meridian. The Texas gulf coast is a wintering place for ducks and geese. Wild turkey is abundant in southwest Texas. There are more than eight hundred species of birds. Notable is the mockingbird, the official state bird of Texas.

There is extensive commercial fishing in the coastal waters. The commercial crop was 20,271,878 pounds in 1946, of which the shrimp catch accounted for 15,533,034 pounds. Valuable salt-water fish include the red snapper, red fish, drum, salt-water trout, and flounder. The tarpon is plentiful and sought purely as a game fish. Fresh-water varieties include the cat, pickerel, perch, gaspergou, and buffalo. The construction of a number of large reservoirs has greatly increased fresh-water fishing. There are eleven state and six Federal fish hatcheries.

*Loading crude sulphur for shipment near Freeport, Texas. In the background is the blasted face of a yellow sulphur mountain.*

PHILIP GENDREAU

Poisonous reptiles are varieties of the rattlesnake, water moccasin, copperhead, and coral snake. The harmless horned toad, a diminutive lizard of the iguana family, is the subject of tall tales and legends.

## ECONOMIC RESOURCES AND ACTIVITIES

**Raw Materials.** The economy of Texas is characterized primarily by a large production of raw materials in excess of the state's consumption requirements. These include petroleum, natural gas, sulphur, cotton, wheat, grain sorghums, grapefruit, winter vegetables, rice, forest products, beef cattle, sheep, wool, goats, and mohair.

**Minerals and Mining.** Since 1935 Texas has consistently been the leading state in the value of minerals produced. The value of minerals produced in Texas in 1950 was approximately $2,582,000,000. Petroleum contributes most of this total. It is followed by natural gas and sulphur. Rapid development is shown by the fact that Texas minerals produced in 1900 were valued at only $5,316,222. Minerals production is widely dispersed throughout the state. Petroleum is produced in more than half of the counties of Texas, and sulphur is found in several counties along the Gulf Coast. The production and value of the principal minerals produced in Texas in 1949 was as follows:

| *Mineral* | *Production* | *Value* |
|---|---|---|
| Petroleum, *bbls.* | 743,990,000 | $1,919,494,200 |
| Natural gas, *M. cu. ft.* | 2,588,921,000 | 163,101,923 |
| Natural gasoline, *M. gals.* (1948) | 1,861,164 | 170,306,000 |
| Sulphur, *long tons* | 3,678,196 | 66,208,000 |
| Cement, *bbls.* | 12,349,219 | 24,111,833 |
| Salt, *tons* | 1,637,388 | 2,453,803 |

There was also commercial production of iron, coal, coke, copper, lead, magnesium, and various other products.

**Agriculture.** There were 384,977 farms in Texas in 1945, valued at $3,574,997,897. Owners operated 237,607 farms; tenants, 144,792; and managers, 2,578. The land had an average value of $25.29 per acre. By 1950 the number of farms had declined to 331,494 and by 1951 the value had increased to approximately $4,800,000,000. There is a great variation in farm characteristics according to region, with the average farm in some east Texas counties containing about 100 acres while the average farm in some west Texas counties may contain 10,000 acres.

The principal farming development from the Civil War to 1926 was the increase in cultivated acreage devoted primarily to cotton. In 1926 cotton acreage reached an all-time high of 17,749,000, and a record crop of 5,628,000 bales was produced. From 1927 to 1949 the cotton acreage showed a steady decline, but in 1949, although only 10,725,000 acres were harvested, a record 5,900,000-bale crop was produced. From 1930 to 1945, the number of farm tenants declined from 301,660 to 144,792. The sharecropper class of tenant declined from 105,122 to 24,507. In the same period, the total number of farms declined from 495,489 to 384,977, and the average acreage increased from 251.7 to 367.1. The farm population decreased from 2,332,693 to 1,487,829. By 1950 farm population had declined to 1,307,000. Cash receipts from farm crops in 1950 totaled $2,147,062,000. Texas ranked third in the value of agricultural products, behind Iowa and California.

Tractors and tractor equipment have played a great part in the development of modern agriculture in Texas. The number of tractors in use on Texas farms has increased from approximately 9,000 in 1920 to an estimated 250,000 in 1951.

*Irrigation.* Irrigated acreage totaled 2,884,700 in 1948. The irrigated area is distributed as follows: Panhandle High Plains, 1,384,600 acres; Pecos Valley and Trans-Pecos, 193,300 acres; West Central, 19,200 acres; Rio Grande Plain, 150,300 acres; Lower Rio Grande Valley, 592,100 acres; Coast Prairie, 525,420 acres; and other areas, 19,780 acres. An extensive irrigation project that will make use of the impounded flood waters of the Rio Grande is now being developed. This project is made possible by a treaty signed by the United States and Mexico in 1945.

LEADING TEXAS CROPS
(1950)

| *Crop* | *Acreage Harvested* | *Production* |
|---|---|---|
| Cotton lint | 6,700,000 | 2,900,000 bales |
| (1951 estimate) | 12,810,000 | 5,000,000 bales |
| Wheat | 2,839,000 | 22,712,000 bu. |
| Sorghum, grain | 6,474,000 | 148,818,000 bu. |
| Hay | 1,149,000 | 1,281,000 tons |
| Corn | 3,130,000 | 65,730,000 bu. |
| Oats | 1,386,000 | 27,027,000 bu. |
| Barley | 133,000 | 1,729,000 bu. |
| Peanuts | 490,000 | 330,750,000 lb. |

**Livestock.** Extensive grasslands made Texas a livestock region from the beginning of settlement by white men, and the prairies of south Texas were covered with wild cattle, strayed from Spanish herds, at the time of early Anglo-American immigration. Increase of cattle in Texas and demand in the North before means of transportation existed, led to the trail-driving era which culminated in the 1870's and 1880's, during which an estimated 12,000,000 cattle went from Texas up the Chisholm, Fort Dodge, and other trails.

The introduction of barbed wire ended the open range and initiated the era of large ranches, which in turn was succeeded in most parts of Texas by the crop farm and the small livestock farm. However, wide areas of west and southwest Texas, and some of the broken lands of the north central and northwest portions are best adapted to large-scale ranching; there were in 1949 a number of ranches of more than 100,000 acres each and in some wide areas the average was above 10,000 acres. Shorthorns and Herefords, crossed with Brahmas, are the predominant beef breed. Texas is the first-ranking state in number of sheep and production of wool and in number of Angora goats and production of mohair.

Total cash income from all livestock and livestock products in 1950 was $879,681,000. The United States Department of Agriculture gives the following estimate as to the number and value of livestock on Texas farms in 1951:

| *Kind* | *Number* | *Value* |
|---|---|---|
| Cattle, all | 9,260,000 | $1,314,920,000 |
| Milk cows only | 1,309,000 | 236,929,000 |
| Hogs | 1,786,000 | 43,578,000 |
| Sheep | 7,119,000 | 154,962,000 |
| Goats | 2,433,000 | 23,114,000 |
| Horses | 324,000 | 9,072,000 |
| Mules | 120,000 | 4,920,000 |
| Chickens | 25,884,000 | 29,767,000 |
| Turkeys | 755,000 | 3,775,000 |

**Manufacturing.** The refining of oil and the processing of heavy commodities close to point of production primarily for further fabrication characterize the manufacturing industry of Texas. Recent years have seen a rapid advancement in the production of consumer goods. There were 7,128 manufacturing establishments in Texas in 1947, with 297,053 wage earners receiving $755,411,000 in wages. The total value of manufactured goods in that year was $1,727,464,000.

LEADING TEXAS INDUSTRIES
(1947)

| | *Avg. No. of Persons Employed* | *Value Added by Manufacture ($1,000)* |
|---|---|---|
| Petroleum and coal products | 37,696 | 359,680 |
| Food and kindred products | 57,784 | 337,558 |
| Chemicals and allied products | 23,552 | 234,496 |
| Machinery, except electrical | 23,299 | 129,575 |
| Lumber and products, except furniture | 30,694 | 95,988 |
| Printing and publishing | 17,756 | 92,467 |
| Transportation equipment | 20,735 | 91,893 |
| Apparel and related products | 22,008 | 71,128 |

Other manufactures in Texas are fabricated metal products, primary metal processing, paper and allied products, lumber and fixtures, textile mill products, leather and leather products, stone, clay, and glass products, and electrical machinery.

**Transportation.** The wide area of Texas and the lack of navigable rivers have, from the beginning, confronted its people with problems of transportation and distribution. The first railroad began operation in 1853, but it was not until 1873 that the isolated Texas railway system was connected with that of the other states. In 1950, there were 15,559 mi. of main-line track in Texas. This made Texas the leading state in main-line mileage. There is constant traffic movement in the thirteen Texas deepwater ports, notably those of Houston, Galveston, Texas City, Beaumont, Port Arthur, and Corpus Christi.

Much of the transportation in Texas is carried on by highway. In 1950 the Texas Highway Department had control over 34,929 mi. of highway. In addition there were 164,707 mi. of roads subject to county control. More than 60,000 mi. of the country roads in Texas were classed as unimproved. Texas highways are financed by 75 per cent of the proceeds of a 4-cent gasoline tax, license fees, and Federal grants. In 1952 there were no toll roads that were under control of the Highway Department.

Warm climate and open terrain have favored aviation in Texas, and the Federal Government in World War I and World War II centered much of its military aviation training there. In 1951 eleven commercial airlines were operating in Texas.

## GOVERNMENT AND POLITICS

**Government.** The Texas state government is characterized primarily by the large powers given to the legislative branch, by a large and loosely integrated administrative system, and by a judiciary elected by popular vote. The state constitution is a document of 35,000 words and is characterized by a great amount of detail of statutory level. From its adoption in 1876 through 1952, the constitution has been amended more than 100 times. Peculiar features are its detailed bill of rights, its community-property provision giving husband and wife equal title in jointly acquired property, and its restriction on the placing of encumbrance upon a homestead. The constitution is similar to those of other states, but some of its provisions dealing with the public domain and with property rights were derived from Spanish law.

The administrative system is headed by the governor, who is assisted in his executive duties by a lieutenant governor, attorney general, comptroller of public accounts, treasurer, superintendent of public instruction, commissioner of agriculture, and commissioner of the General Land Office, all of whom are elected by popular vote for two-year terms. In addition there is the three-member Railroad Commission, which has jurisdiction over all transportation and oil and gas laws and is elected to six-year, overlapping terms. There were 130 operative officials, boards, and commissions as of Dec. 31, 1946. Most of the nonelective officials are appointed by the governor, in some instances with the advice and consent of the Senate and in some instances without such advice and consent. In 1952 the governor of Texas was Allan Shivers, Democrat.

The legislature consists of a House of Representatives of 150 members and a Senate of 31 members. It meets biennially the second Tuesday in January of odd-numbered years, and is limited to 120 days in regular session, with privilege of ex-

EWING GALLOWAY

tending the session indefinitely but with a pay cut from $10 to $5 a day. The governor may call extraordinary sessions of the legislature.

The judiciary is headed by a supreme court of nine members and a court of criminal appeals of three members, with an assisting commission of two members. The supreme court has final jurisdiction in civil cases and the court of criminal appeals has final jurisdiction in criminal cases. There are eleven courts of civil appeals in the state. These courts have jurisdiction, respectively, over the eleven districts into which the state is divided. The district court is the chief trial court. There are also a number of county courts and justice of the peace courts.

Texas has twenty-two representatives and two senators in the United States Congress. In 1953 the United States Senators from Texas were Lyndon B. Johnson and Price Daniel, both Democrats.

**State Finance.** During the fiscal year which ended Aug. 31, 1952, the Texas government had an income of $819,388,306.02. This total included $130,064,695.99 listed as "Non-Revenue Receipts." The largest items of state income included $155,985,609.28 from gross receipts and production taxes; $104,734,439.45 from the gasoline tax; $34,888,669.93 from the cigarette tax; $35,406,899.30 from automobile license fees; $24,256,967.15 from the ad valorem tax; $43,355,491.08 from land sales, rentals, and royalties; and $148,357,538.10 in county, Federal, and other aid.

During the same year total governmental cost was listed as $617,210,759.40, and there were in addition "Non-Cost" payments of $154,909,272.49. The chief items of governmental expenditure were: highways, $137,718,848.77; public schools, $200,254,107.02; public welfare, $120,053,141.73; and higher education, $41,861,548.59.

**Banks.** On Dec. 30, 1950, there were 442 national banks and 449 state banks operating in Texas. The national banks had resources of $6,467,275,000 and the state banks had resources of $1,427,679,000.

**Political Movements.** The dominant Democratic party has won all state elections from the beginning of statehood in 1845 through 1952 with the exception of the elections of the Reconstruction period, when suffrage was restricted, and the election of 1859, when the Know-Nothing party won with the aid of insurgent Democrats. The state has voted Democratic in presidential elections with the exceptions of 1928 and 1952. In 1928 the electoral vote of the state was cast for Herbert Hoover and in 1952 it was cast for Dwight D. Eisenhower.

**Military Activities.** The Texas state military activities are directed by the adjutant general, appointed by the governor. The Texas State National Guard had reassigned to it, after World War II, its historic Thirty-Sixth Division and, in addition, an armored division.

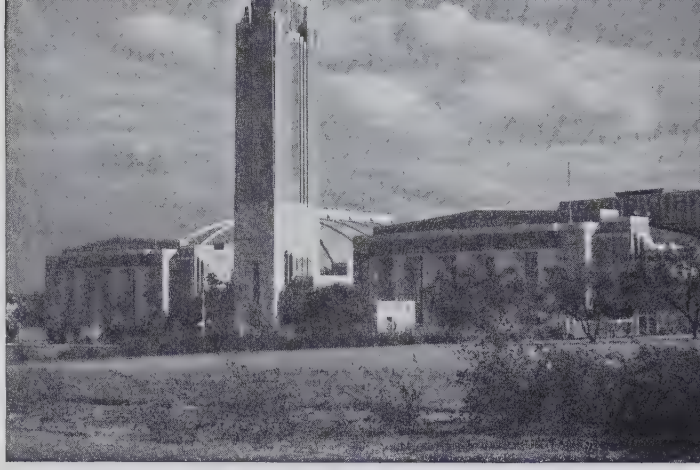
## SOCIAL AND CULTURAL INSTITUTIONS

Influencing factors in the educational and social conditions of Texas have been the wide dispersal of population over a great area, the relatively large rural population, the rapid economic development of the state, the great variation in local financial ability to support schools, and the appreciable population of substandard income groups in some areas, including Latin Americans along the border, the Negro population of east and central Texas, and the sharecropper tenants, both white and Negro, of the east, central, and south Texas cotton-growing areas.

**Education.** The state system of public education is headed by a state Commissioner of Education appointed by a Board of Education, consisting of twenty-one members. Education is compulsory in Texas for all children from seven to sixteen years of age inclusive; whites and Negroes are segregated in separate schools. In 1949-1950 there were approximately 2,500 school districts in Texas. Most of these were common, or rural, districts, but about 1,000 of them were independent districts. During that year the scholastic population was 1,557,798 and the average daily attendance was 1,151,960. The system employed more than 54,000 teachers in 1949-1950, and these received an average salary of $3,183.

An important factor in the early development of education in Texas was the allocation of large quantities of the public domain to the schools. Under the agreement by which Texas was annexed to the Union, the state retained all of its public domain, amounting at that time to considerably more than one half the area of the state. During the period of Republic and early statehood, a total of 49,518,332 acres were put aside for the benefit of common schools and higher education.

The state's largest institution of higher education is the University of Texas, at Austin. Other leading state educational institutions are the Agricultural and Mechanical College of Texas, at College Station; Texas Technological College, at Lubbock; Texas State College for Women, at Denton, and nine other senior state colleges. Until 1946, the principal higher educational institution for Negroes was the Prairie View Normal College at Prairie View. The Fiftieth Legislature (1947) established the Texas State University for Negroes at Houston, and converted Prairie View Normal College into an agricultural and mechanical college for Negroes. Principal church and private educational institutions of Texas include Rice Institute, at Houston; Baylor



CHARLES PHELPS CUSHING

*THE WILL ROGERS MEMORIAL, FORT WORTH, TEXAS*

University, at Waco; Southern Methodist University, at Dallas; Texas Christian University, at Fort Worth; and St. Mary's University and Our Lady of the Lake College, at San Antonio.

**Social Measures.** The state public welfare program is administered by the Department of Public Welfare. Funds used by this department are received in part from the state and in part from the national government. In May 1950, a total of 225,187 persons received pensions averaging $33.63. In the same month, payments were made to 53,608 dependent children in 19,123 families. The payments averaged $24.68 per family. Payments are also made to the needy blind, to Confederate veterans, and to the widows of Confederate veterans. The state maintains a number of eleemosynary institutions and grants assistance to about 300 Alabama and Coushatta Indians who live on a small reservation in Polk County. The prison system consists of the main plant at Huntsville and eleven prison farms.

**Cultural Activities.** The largest library is that of the University of Texas with over 1,000,000 volumes, notable for its special libraries, including the Latin American collection, the Wrenn Library of first editions, the Southern Collection, the Texas Collection, and the Stark Collection. Many historic documents are found also in the Texas State Library, which contains 225,000 volumes. The Browning Collection of Baylor University, Waco, is also notable. The state's principal museum is the Texas Memorial Museum at the University of Texas, Austin.

There are three major symphony orchestras in Texas: the Houston, the Dallas, and the San Antonio. In addition to

*STADIUM OF TEXAS CHRISTIAN UNIVERSITY, FORT WORTH*

*Centuries of erosion have produced these strange rock towers in Palo Duro Canyon State Park.*

giving an annual series of concerts, these organizations sponsor various activities, such as the commissioning of contemporary composers, the awarding of prizes for compositions of resident Texas composers, and the presentation of productions of grand opera.

The Fort Worth Civic Opera utilizes resident talent, importing well-known stars only if they are needed for particular productions.

The Little Theatre in Dallas is an outstanding nonprofessional group, and little-theatre groups are also found in Houston, Austin, and at the University of Texas, at Baylor University, at Southern Methodist University, and at other educational institutions.

## POPULATION

**General Statistics.** The Census of 1950 gave Texas a population of 7,711,194, or 28.8 per sq. mi. This was an increase of 20.2 per cent over the population of 1940. Texas ranked sixth among the states in population in 1950. In that year, 62.7 per cent of her people were classed as urban and 37.3 were classed as rural. A century earlier 96.4 per cent of the people had been classed as rural and only 3.6 per cent as urban.

**Ethnic Groups.** The Census of 1950 classes 88.5 per cent of the people of Texas as white and 11.5 as nonwhite. Most of the white population is of Anglo-American origin. There are, however, a large number of Latin Americans and numerous citizens of German, Italian, or Czech origin. Aside from many of the Latin Americans, there are very few Texans who can be classed as foreign born.

**Labor Statistics.** There were 5,600,000 persons 14 years of age and older in 1950. The total labor force numbered 3,006,000 (2,264,000 male and 742,000 female). The civilian labor force numbered 2,935,000, of whom 95,000 were listed as unemployed.

**Religion.** Most Texans who are church members belong to Protestant organizations. The Baptist, Methodist, and Presbyterian churches are the largest of the Protestant groups. There are also many Catholics in Texas, especially in the counties bordering Mexico.

## RECREATIONAL ASSETS AND HISTORIC SITES

Principal recreational regions are: (1) the Trans-Pecos Mountains; (2) the Edwards Plateau with its innumerable spring-fed streams; (3) the beaches of the Gulf Coast; and (4) the east Texas forest area. The Big Bend National Park, of 708,221 acres, was established in 1944 and, after a wartime delay, was under development in 1946. There are four national forests—Sam Houston, Davy Crockett, Angelina, and Sabine—totaling 661,700 acres in east Texas; these national forests have been set aside for both timber conservation and popular recreation. Under administration of the Texas State Parks Board are thirty-six developed parks, of which the Palo Duro Canyon State Park, of 15,103 acres, is the most extensive.

Notable points of historic interest are the Alamo, at San Antonio, "Cradle of Texas Liberty," and the San Jacinto Battlefield Monument near Houston, a 570-foot shaft. Most notable of Texas public buildings is the state capitol, which was built of pink granite that had been quarried near Austin; this building was one of the world's largest capitols at the time of its completion in 1888.

## HISTORY

**Exploration.** The first written record of the landing of the white man in Texas is that of the Pánfilo de Narváez expedition, which was shipwrecked in the vicinity of present Galveston Island in 1528, though it is probable that the expedition of Alvarez de Piñeda, skirting the gulf coast in 1519, made temporary landings. There followed the period of the conquistadores and the search for the Seven Cities of Cibola, during which Francisco Vásques de Coronado, Hernando de Soto, Antonio de Espejo, and other explorers crossed portions of the state. Other than searching for treasure, however, the Spanish gave little attention to establishing their sovereignty until the expedition of Robert Cavelier de La Salle in 1685 aroused suspicions of French designs. Beginning in 1689, a series of Spanish missions was established, and the Spanish effort continued intermittently until the secularization of the missions in 1793. The period, however, left a colony of only about 7,000 white persons, largely in the vicinity of San Antonio. The aboriginal Indian population of the state consisted of the crop-growing Caddo tribes, who lived on the rivers of the eastern area; the fierce, roving Comanches and the Lipan Apaches, who ranged over the western part of the state; and a number of fish-economy tribes, who had settled along the coast.

**Political Development.** Interest in Anglo-American colonization began with the petition of Moses Austin of Missouri to the Spanish government in 1820. His death that year left fulfillment of his responsibilities to his son, Stephen F. Austin, who, in 1821, renegotiated the agreement with the new independent Mexican government and established a colony on the Lower Brazos, which was followed by a number of other colonial enterprises which swelled the population of Texas to more than 20,000.

There was soon conflict, however, between the Anglo-American colonists and the Mexican authorities over the establishment of free schools, the levying of imposts by Mexico, and the maintenance of constitutional government. This culminated in the Texas revolution of 1835-1836, during

which the dictator, General Lopez de Santa Anna, was defeated at the Battle of San Jacinto, on Apr. 21, 1836, near present Houston, by the Texan army under General Sam Houston. Texas' independence was declared in a convention at Washington-on-the-Brazos, on Mar. 2, 1836, but was followed shortly thereafter by the tragic defeat and destruction of a small Texan force under Colonel William Barrett Travis by Santa Anna's forces at the Alamo, San Antonio, on March 6. The victory at San Jacinto was celebrated by the establishment of the Republic of Texas, which lasted from 1836 through 1845 and received the recognition of the United States, Great Britain, France, and some of the German states, though Mexico never relinquished its claim. The presidents of the Republic in succession were: David Burnet, provisional; Sam Houston; Mirabeau B. Lamar; Houston (second term); and Anson Jones. The period of the Republic was beset primarily by financial difficulties, the constant threat of invasion by Mexico, and a continuing struggle with the Indians.

The annexation of Texas to the United States as the twenty-eighth state, on Dec. 29, 1845, precipitated the Mexican War, which was ended by the Treaty of Guadalupe Hidalgo. By the terms of this treaty, Mexico relinquished its claim to Texas and also ceded New Mexico and California to the United States.

**Civil War Period.** Though Texas seceded to join the Southern Confederacy it saw little of military action except the capture and recapture of Galveston Island, the unsuccessful attack of United States troops on Sabine Pass, and two clashes in the Rio Grande Valley, where Federal attention had been drawn to Confederate cotton exports by blockade running. From the end of the war until Mar. 30, 1870, the date of readmission, Texas was under the administration of the Reconstruction governors, during which secessionist elements were barred from voting by the "ironclad oath." In the election of 1873, however, Richard Coke defeated the incumbent, E. J. Davis. Davis then attempted to have the election declared void, and for a few days the state capitol at Austin sheltered the armed camps of the two contenders. President Ulysses S. Grant refused to sustain Governor Davis, however, and the Reconstruction, or "carpetbag," rule was thus ended.

**Economic Development.** The subsequent history of Texas has been characterized primarily by economic rather than political and military developments. Railroad construction boomed during the seventies, eighties, and nineties, and the western area changed from the open range to the livestock range, while the farmer followed the cowman in the western advance. Momentous was the discovery of the first big oil field, Spindletop, near Beaumont, in 1901, inaugurating what might be called the oil era of Texas economy. The first two decades of the twentieth century were characterized by the rapid development of the High Plains and the Corpus Christi and Rio Grande Valley territories and the rapid commercial and industrial expansion which built the cities of Houston, Dallas, San Antonio, and Fort Worth and brought the excavation of the deepwater ports along the coast. Because of the basic nature of its frontier economy, the state suffered somewhat less during the economic depression of 1929-1934 than the more industrial areas of the country, and it revived even before the boom in war industries began in 1941.

**Political Controversy.** The first noteworthy political event of the post-Civil War period was the administration of Governor James Stephen Hogg, 1891-1895, which enacted railroad control legislation, including the establishment of the State Railroad Commission in 1891, the ouster of a large oil corporation and considerable legislation directed at outside monopoly control of Texas oil and other resources. In 1915 Governor James E. Ferguson was elected, but he was ousted in 1917 by impeachment. This began a long controversy over "Fergusonism," during which the ousted governor's wife was twice elected chief executive, in 1925-1927 and 1933-1935. Great political excitement was also aroused during the campaigns involving W. Lee O'Daniel and in the 1946 campaign, in which the candidates were Homer P. Rainey and Beauford Jester.

EWING GALLOWAY

**Military Participation.** Texas contributed notable military service in both World War I and World War II through its man power and the large number of aviation, ground

force, and navy training installations maintained in the state. In both wars the Thirty-Sixth Division (Texas National Guard) was mobilized in its home state. During World War I, Texas contributed nearly 210,000 men to the armed forces; during World War II, the state contributed 585,000 men and 9,704 women to the army, and 196,118 men and 3,150 women to the Navy. S. McG. and R. W. S.

**TEXAS, AGRICULTURAL AND MECHANICAL COLLEGE OF,** an accredited, state-controlled, and state-supported university for men, at College Station, Tex. The total university grounds include more than 8,300 acres, including branches at Stephenville and Arlington. The school is a land-grant college and was originally founded in 1862 under the provisions of the Morrill Act. Students were admitted in 1876.

The divisions of the university include agriculture, engineering, veterinary medicine, arts and sciences, graduate school, experiment stations, and forestry service. These branches offer the A.B. in arts and sciences; the B.S. in business, various engineering curricula, and agriculture; the D.V.M. (veterinary medicine); and the Ph.D. Courses in food technology and flight training have been recent additions. Courses in military science are required, and Army R.O.T.C. units provide this training. Dormitories and dining halls are available and there are no fraternities on the campus. Scholarship assistance is generous and a large fund has been established for loans to students. *For statistics see* Colleges and Universities. J. R. To.

**TEXAS, UNIVERSITY OF,** an accredited, coeducational, state-controlled institution occupying approximately 1,100 acres. The main campus is located at Austin, Tex., the Medical Branch at Galveston, the Dental Branch and the M. D. Anderson Hospital for Cancer Research at Houston, and the College of Mines and Metallurgy at El Paso. Cooperating with the Medical Branch are the Sealy and Smith Foundation, the John Sealy Hospital, the State Hospital for Crippled and Deformed Children, and the Galveston State Psychopathic Hospital. The university was organized by legislative act in 1881 and first instruction was offered in 1883, when the College of Arts and Sciences and the School of Law opened in Austin. The other divisions were founded as follows: School of Medicine, 1891; College of Pharmacy, 1893 (moved to main university at Austin, 1927); College of Engineering, 1894; College of Nursing, 1897; School of Education, 1906; Division of Extension, 1909; Graduate School, 1910; College of Business Administration, 1922; College of Fine Arts, 1938; Dental Branch, 1943; and School of Architecture (within the College of Engineering), 1948. The College of Mines and Metallurgy was made a branch of the university in 1919 by legislative act but has its own president and administrative officers.

The degrees offered include the A.B.; the B.S. in education, elementary education, and physical education, architectural, chemical, civil, electrical, and mechanical engineering, geology, home economics, medicine, nursing, and pharmacy; the B.J.; the B.Arch.; the B.B.A.; the LL.B.; the M.B.A.; the M.J.; the M.Ed.; the M.S.; the Ed.D.; the M.D.; and the Ph.D. Training for the armed forces is under the direction of the Navy R.O.T.C. and Army R.O.T.C. The local chapter of Phi Beta Kappa was founded at the University of Texas in 1905.

The university is one of four southern universities receiving the Carnegie Corporation grant for the five-year experimental program to develop permanent university centers for Latin American studies. Baylor, Rice, and the University of Houston are co-operating with Texas University in the establishment of the new Texas Medical Center at Houston. Extensive library facilities are available in the main library on the Austin campus and in the separate libraries operated for the various divisions. Featured are the Bieber collection of American poetry, the Texas collection, the Latin American collection, the archives collection, material on Southern history, and the Abraham I. Schechter collection of Hebraica and Judaica.

Scholarships offered include one to each accredited secondary school in Texas. There is a loan fund. Employment opportunities enable more than half of the students to earn part of their expenses. The sororities and fraternities also provide additional living accommodations. *For statistics see* Colleges and Universities. J. R. To.

**TEXAS CHRISTIAN UNIVERSITY,** an accredited, privately controlled coeducational institution, affiliated with the Disciples of Christ Church. The buildings and grounds occupy approximately 150 acres at Fort Worth, Tex. Five miles from the main campus is the affiliated Harris College of Nursing. The institution was founded in 1873 by Addison and Randolph Clark at Thorp Springs, Tex., under the name of Add-Ran Christian University. The charter was granted the following year. In 1895 the university moved to Waco, where it remained until the Fort Worth site was established in 1910. The name was changed to the present form in 1902.

Divisions include liberal arts, nursing, fine arts, education, business, evening college, graduate school, and the Brite College of the Bible. Special programs are given in engineering, home economics, and journalism. The degrees offered include the A.B., the B.S., the B.F.A., the B.D., the B.C.S., the M.S., and the M.A.

Undergraduate students from out of the city who are under 21 years of age must live in the university residence halls unless special permission for other arrangements is obtained. Graduate fellowship and undergraduate scholarship aid is generous, and there are opportunities for self-help. There are also some scholarships and fellowships covering tuition, fees, books, and so forth, which are administered specifically for foreign students in the university. *For statistics see* Colleges and Universities. J. R. To.

**TEXAS CITY,** an industrial city in southeastern Texas, in Galveston Co., situated on a channel to Galveston Bay, 30 mi. southeast of Houston. Located in a large natural-gas field, the city is largely industrial and has a land-locked inner deep-water harbor 875 to 1,100 ft. wide and 5,300 ft. long. Texas City was founded in 1821 by Jim Campbell, one of the retired lieutenants of the pirate Jean Lafitte. In 1892 a group of shipping men from the Great Lakes area arrived at the site and soon began developing the city and port. Texas City was incorporated in 1911 and has the commission form of government. In April 1947 the city was almost totally destroyed by fires which raged for three days. The fires were started on April 16 by an explosion on the freighter *Grandcamp,* containing ammonium nitrate, docked in the harbor. The fire spread to docks, oil tanks, and the Monsanto Chemical Company plant, which set off chains of fires and explosions throughout the area. On April 17 another freighter, *High Flyer,* also loaded with ammonium nitrate, exploded and the city was declared in a state of emergency. The fires were extinguished finally on the next day, with the result of an estimated property loss of $50,000,000, 512 known

dead, 3,000 injured, and approximately 300 missing. One year later, on April 16, 1948, with a single exception, the city's industrial plants were back in operation and the production figures were equal to or greater than those at the time of the tragedy. Manufactures include tin smelting, petroleum refining, and the production of chemicals. As a port, Texas City ships ore, tin, oil, potash, wool, grain, chemicals, and food products. Transportation is supplied by the Burlington-Rock Island, the Missouri-Kansas-Texas, the Missouri Pacific, the Santa Fe, the Southern Pacific, and the Texas City Terminal railroads. Pop. 1950, 16,620.

*Texas City under dense smoke from the blasts and fires caused by explosions of ammonium nitrate on a freighter in the harbor on April 16, 1947*

SOUTHERN NEWSPIX

**TEXAS COLLEGE OF ARTS AND INDUSTRIES,** an accredited, coeducational, state-controlled technological institution located on 451 acres in Kingsville, Tex. It was chartered as South Texas State Teachers College in 1917 and first instruction was offered in 1925. The name was changed to the present form with the granting of a new charter in 1929. The Industrial Arts Department was established in 1946. The Agriculture Department was expanded through the acquisition in 1947 of a lease on the 2,850-acre Kingsville Naval Auxiliary Air Station. The training center for citrus and vegetable courses is situated in the Rio Grande Valley, 106 mi. from the campus. The degrees offered include the A.B. and the B.S. in liberal arts; the B.S. in agriculture, home economics, elementary education, and secondary education; the B.B.A.; the B.Mus.; the M.S.; and the M.A. The B.S. is also offered in general, chemical, electrical, mechanical, and natural-gas engineering. Residence halls are maintained for students who do not commute. Some scholarship and loan assistance is available. *For statistics see* COLLEGES AND UNIVERSITIES. J. R. To.

**TEXAS FLY** or **TEXAS FRUIT FLY,** the common name of *Anastrepha ludens,* one of the fruit flies of the family Trupaneidae, or Trypetidae. This fly has long been a serious pest of citrus fruits in southern Texas. Great progress has been made in reducing the losses resulting from damage to fruit by the larvae, which somewhat resemble the maggots of the housefly. Many kinds of tropical and subtropical fruits are attacked by the Texas fly in Central America. *See also* FRUIT FLY. C. H. Cu.

**TEXAS STATE COLLEGE, NORTH,** an accredited, coeducational, state-controlled, and state-supported institution located on 150 acres in Denton, Tex. It was chartered as Texas Normal College in 1890, when first instruction was granted. It was made a state college and the name was changed to North Texas Normal College in 1901. The change to North Texas State Teachers College was made in 1923, and to the present in 1949. The Graduate Division was added in 1935. Under a recent reorganization the following divisions were set up: the College of Arts and Sciences and the schools of Business Administration, Education, Home Economics, and Music. A permanent program in health education with a full-time director has been added. Special courses are given in the training of teachers of handicapped children. Degrees offered include the A.B., the B.S., the B.B.A., the B.Mus., the B.S. in library service and home economics, the M.S., the M.Mus., the M.B.A., and the M.A. The library includes special collections on Latin America, children's literature, and rare Texas historical items. Scholarship aid is limited to small grants to high-school valedictorians. Dormitories and dining halls are available. *For statistics see* COLLEGES AND UNIVERSITIES. J. R. To.

**TEXAS STATE COLLEGE, WEST,** an accredited, coeducational, state-controlled, and state-supported teacher-training institution and school of liberal arts and business administration. It is located in Canyon, Tex., on a campus of 272 acres. The charter was originally granted to West Texas State Normal College in 1909 and first instruction was given in 1910. The name was changed to West Texas State Teachers College in 1923, and to the present in 1949. The four-year courses leading to the A.B. and the B.S. degrees were introduced in 1917. Courses leading to the M.A. were first offered in 1932, and in 1937 a curriculum was established leading to the M.B.A. The vocational and trade school was opened in 1947. Degrees offered include the A.B., the B.S., the B.B.A., the B.S. in education, the M.B.A., and the

M.A. Scholarships remitting the fees of the freshman year are available to high-school honor graduates. Additional financial aid is available in special cases. Dormitories and dining halls and some housing for married couples are provided. *For statistics see* COLLEGES AND UNIVERSITIES.

J. R. To.

**TEXAS STATE COLLEGE FOR WOMEN,** a state-controlled, accredited college of arts and sciences, occupying a 172-acre campus in Denton, Tex. It was founded in 1901 and first instruction was offered in 1903. The degrees offered include the A.B. and the B.S. in liberal arts; the A.B. and the B.S. in business administration; the B.S. in library science; and the M.A. Among the many departments in which majors may be taken are biology, chemistry, English, fine and applied arts, health and physical education, home economics, music, education, and speech. All students are required to reside in the dormitories or in approved student houses. Tuition scholarships are offered to high-school valedictorians of the state, and there is a student loan fund. Financial help in the way of campus jobs and assistantships is available to a substantial number of students. *For statistics see* COLLEGES AND UNIVERSITIES. J. R. To.

**TEXAS STATE TEACHERS COLLEGE, EAST,** an accredited, coeducational, state-controlled, and state-supported institution located on a 210-acre campus in Commerce, Tex. Established in 1894 as East Texas Normal College, it became a state institution in 1917. The name was changed to the present form in 1923. Degrees offered include the A.B., the B.S., the B.B.A., the B.Mus.Ed., the M.S., and the M.A. Majors and minors may be chosen in art, science, English, history, home economics, industrial education, library science, music, and physical education. Scholarship aid is limited, but there are some opportunities for students to earn part of their expenses. There is a student loan fund. Student housing must be approved by the deans of men and women. Dormitory facilities are limited in capacity. *For statistics see* COLLEGES AND UNIVERSITIES. J. R. To.

**TEXAS STATE TEACHERS COLLEGE, SOUTHWEST,** an accredited, coeducational, state-controlled teacher-training institution occupying 76 acres in San Marcos, Tex., about 30 mi. south of Austin. It was established in 1899 as Southwest Texas State Normal School. First instruction was given in 1903, and the four-year course leading to the bachelor's degree was offered in 1918. The name was changed to the present form in 1923. Graduate work leading to the master's degree was added in 1936. Courses in special education for handicapped children were introduced in 1945. The degrees offered include the A.B., the B.S., the B.B.A., the B.Mus., and the M.A. Scholarship aid in the form of a remission of freshman fees is offered to the honor graduates of the high schools in Texas. Opportunities for self-help enable a limited number of students to earn part of their expenses. All students must live in college dormitories, cooperative houses, or approved student homes. *For statistics see* COLLEGES AND UNIVERSITIES. J. R. To.

**TEXAS TECHNOLOGICAL COLLEGE,** an accredited, coeducational, state-controlled institution, offering courses in technology and in the arts and sciences. Established by legislative enactment in 1923, it occupies a campus of over 2,000 acres in Lubbock, Tex. First instruction was offered in 1925. The undergraduate divisions of agriculture, arts and sciences, business administration, engineering, and home economics date from the foundation of the college. The Graduate Division was established in 1936. Degrees offered include the A.B., the B.B.A., the B.S. in agriculture, home economics, education, and various engineering programs. Graduate degrees of M.B.A. and M.A. are offered. Training for the armed forces is under the direction of the Army R.O.T.C. Scholarships and student loans are available and there are opportunities for earning part of the expense of the college course. Dormitories are available for men and women. Other living quarters must be approved by the college. *For statistics see* COLLEGES AND UNIVERSITIES.

J. R. To.

**TEXCOCO** [tesko'ko], the largest of the five shallow lakes, irregular in shape and without drainage to the sea, which formerly occupied the Valley of Mexico in central Mexico. The Aztec capital, Tenochtitlán, now the site of Mexico City, was built on a system of islands and piles in the lake and connected with the mainland by three causeways, 2 to 5 mi. long. Drainage of the lake, begun by the Spaniards in 1607 and 1608, was completed in the twentieth century, leaving a small marshy area northeast of Mexico City's airport. The maximum depth of the lake was about 7 ft. Elaborate reclamation projects have been undertaken to wash the salts from the old lake bed soils. P. E. J.

**TEXEL** [tɛ'ksəl], largest, westernmost, and southernmost of the West Frisian Islands, lying off the northern coast of the Netherlands. It is 13 mi. long, 6 mi. broad, and 73 sq. mi. in area, and is separated from the mainland (province of North Holland) by the Mars Diep Strait, 1.5 mi. wide. The western part consists of dunes, the eastern of fertile cropland and excellent pasturage for about 35,000 sheep. Steamers from Den Helder on the far northern point of North Holland to Oudeschild on the southeast coast of Texel connect the island with the mainland. De Mok, a naval seaplane station, is at the south end on the inner side. The chief town is Texel (Den Burg op Texel), which has a sixteenth-century church. Koog is a west-coast fishing village and beach resort. Pop. 1952, 10,054.

S. Van V.

**TEXTILE FABRICS.** Textiles are lengths of woven or knitted cloth made of pliable fibers that have been spun into yarns. Textile fabrics are the most commonly used materials for clothing and many household uses. They date from prehistoric times.

**Types of Fibers.** Fibers may be either natural or synthetic, derived from animal, vegetable, or mineral sources. Common properties are strength, pliability, porosity, and adaptability to cleaning and to dyeing and other finishing. Animal fibers, protein in content, include wool, mohair, camel's hair, llama, alpaca, cashmere, vicuña, and silk, the last a product of the silkworm. Rabbit, beaver, and other fur fibers are used for felt, and sometimes combined with other fibers for apparel use. The vegetable fibers include cellulose, cotton, flax, ramie, and jute. Fibers such as hemp, raffia, and wheat are frequently utilized in the making of millinery braids or accessories, but are not considered textile fibers. Mineral fibers, until World War II not widely used for apparel, include asbestos and glass, both valuable because of their fire-resistant qualities. Asbestos, also highly absorbent, is combined with cotton for towels. Glass fibers in curtains and upholstery are used in theatres to reduce the fire hazard. Manufacturers give synthetic fibers various trade names that have no relation to the chemical or physical properties. Rayon is a generic term for synthetic fibers of cellulose or cellulose acetate content. Nylon is a class of synthetic fiber derived from coal products.

**Manufacturing Processes.** The essential processes involved in the manufacture of cloth have remained unchanged throughout history. With the exception of rayon and other synthetic yarns, the principal textile fibers, wool, flax, cotton, and silk, were familiar to ancient peoples. Fragments of wool unearthed from Swiss caves have been identified as dating from 15,000 B.C. Sheer hand-woven linens used for mummy wrappings in ancient Egypt are displayed at the Metropolitan Museum of Art in New York City in a remarkable state of preservation.

*Yarn.* Textile fibers, too short or fragile in themselves, are strengthened by spinning, which twists and binds them together. Still greater strength is imparted by throwing or further twisting the yarns together in preparation for cloth-making.

*Fabrics.* The steps followed in making cloth and other finished textiles are similar, regardless of the kind of fibers used. There are four basic methods: weaving, lacemaking, braiding, and rolling.

Cloth. Woven cloth, the commonest fabric, is made from a series of parallel yarns called warp through which another yarn—the filling, weft or woof—is interwoven. The warp yarns are set up in a loom consisting of a frame holding the heddles, wire strips with eyes for holding the yarns; a warp beam; and the cloth beam. In order to provide sufficient strength for the warp yarns, a gumlike sizing is applied. Then the warp yarns are threaded through the small heddles arranged lengthwise in the loom frame. The heddles raise and lower the desired warp yarns, making a shed through which the filling yarn is run. The shuttle, carrying the filling, interweaves it with the warp. Automatic looms throw the shuttle back and forth across the warp yarns with the heddles changing the arrangement of the yarns at high speed. Stronger yarns along the outer edge form the selvedge. The woven cloth is wound on the cloth beam at the opposite end of the loom.

Woven cloth can be distinguished from other fabrics in that it consists of yarns placed at right angles to each other. The quality of woven cloth is indicated by the "count," meaning the number of warp and filling yarns per square inch; the kind, size, and quality of the yarns; and the particular finishing method used. Narrow woven goods is used as ribbon or for the millinery trade; cloth exceeding 18 in. in width is known as broad silk or broad goods.

A new fabric is created when mill executives determine specifications, kind of fibers, count, weight, size of warp and filling, width, finishing, and approximate cost. Until the invention of artificial silk in 1885 by Hilaire de Chardonnet, cloth was made of wool, silk, linen, or cotton. Low-priced cloth combined wool and cotton or silk and cotton. While natural fibers make excellent fabrics, the high cost and other limitations exclude their use by many consumers. New fabrics combine the advantages of two or more fibers to effect a stronger or more desirable cloth at a lower price.

Lace. Lacemaking preceded the weaving of cloth; man made snares and nets before he conquered the intricacies of weaving. Lace is a meshlike fabric made of knotted yarns following a regular or definite pattern. The production of handmade lace was one of the most important industries of the Venetians during the Renaissance. The pattern, size, and quality of yarns distinguishes each of the various types of lace: Venetian, Chantilly, Rose-point, Alençon, Valencienne, Irish crochet, filet, and so on. Machine-made lace duplicates one or more of the traditional handmade lace patterns. Lace is used for such apparel as evening gowns, blouses, and veils, as well as for curtains, tablecloths, and bedspreads; narrow laces are used as insertions for lingerie, on hats, and in dresses. Knitting, crocheting, and tatting are forms of lacemaking.

Braided Textiles. Braiding is the intertwining of yarns in narrow widths to produce shoe laces, straw braid for hats or table mats, trimmings, etc.

Rolled Textiles. Rolling with steam and pressure or other means transforms fibers into an even, compact, opaque sheet. Felt is made in this manner from wool or fur fibers which become interlocked under heat and pressure. Rubber and plastic materials are also rolled, and in 1947 a process was perfected by which low-grade cotton fibers were made to adhere in an inexpensive paperlike substance. Such fabrics have a variety of uses in both the apparel and the home-furnishings fields.

*Finishing.* Fabrics are finished to remove foreign particles and sizing, and to improve the appearance. Finishing processes include chemical bleaching, dyeing, printing, mercerizing, sanforizing, crease-resistant finishing and finishes that produce a degree of water-repellency. Through these finishing processes yarns are improved in appearance and versatility. Low-cost yarns are made to resemble more costly fibers. Napping, the roughing up of the surface, is used on cotton or outing flannel and blankets. Mercerizing makes cotton stronger and imparts a silklike luster. Glazing adds a smooth, glossy finish to cotton chintz.

### COTTON AND LINEN FABRICS

Typical cotton and linen fabrics include the following:

Batiste: a soft, light, high-count combed cotton, used for infant's wear, blouses, and lingerie.

Bird's-eye or Diaper Cloth: a novelty weave used to produce a soft, absorbent material for diapers and towels.

Broadcloth: a plain weave fabric having a fine cross-wise rib and a count indicating approximately twice as many warp as filling yarns, as 120 by 64 used for shirts, children's and women's dresses.

Byrd Cloth: a plain weave, tightly woven fabric made from combed ply yarns. Developed for explorers under Commander Richard Byrd, it is used for windbreakers and raincoats.

Calico: a plain weave printed fabric, in small motifs, used for aprons and dresses. Originally all fabric from Calcutta, India, was classed as calico.

Cambric: a soft, light, plain weave cotton used for aprons and lingerie.

Canvas: a heavy, stiff, tightly woven cloth used for awnings, tents, sails, and tennis shoes.

Chambray: a plain weave, medium-weight fabric made with colored warp and white filling, desirable for shirts, dresses, blouses, and pajamas.

Chintz: a usually lustrous plain weave fabric, brightly printed or in plain color, used for dresses, curtains, and bedspreads. The frequent glazed finish is available in washable finish which is not destroyed by laundering.

Corduroy: a pile fabric, resembling velveteen, with lengthwise wales, made in various weights for children's play clothes, dresses, robes, upholstery, and sports wear.

Covert: a cotton fabric resembling wool covert which has a steep twill and a two-color warp, used for work clothing and children's overalls.

Crash: a plain weave cloth made from uneven and irregular yarns, used for dresses, tablecloths, or draperies.

Cretonne: a plain weave medium-weight fabric in bold print patterns used for curtains, draperies, and bedspreads.

Damask: cloth with a large Jacquard woven design com-

bining plain and satin weave in decorative effect used for dress goods, tablecloths, napkins, drapery, and upholstery. Damask is generally in one color while brocade is multicolor.

Denim: heavy twill weave cloth with colored warp and white filling, used for overalls and other work clothing and sports wear.

Dimity: a sheer crisp cloth having lengthwise or checkered self cords, used for dresses, blouses, and curtains.

Drill: a medium or heavy closely woven twill used for middies and work clothing.

Duck: a plain weave fabric used for tents, awnings, and couch covers, similar to but lighter in weight than canvas.

Flannelette and Outing Flannel: a soft napped fabric used for nightgowns, summer blankets, pajamas, and diapers.

Gabardine: a cotton fabric of medium weight of closely woven twill weave made to resemble wool gabardine, used for shirts, slacks, dresses, and summer sports wear.

Gingham: a characteristic yarn-dyed cloth of medium weight, identified by woven checks, stripes or plaids, used for clothing and draperies and bedspreads.

Grenfell Cloth: a tightly woven cloth made at the suggestion of Sir William Grenfell as an ideal low-price clothing, wind resistant and water-repellent.

Lawn: a high count, plain weave cloth woven of fine yarns with a crisp finish, used for dresses, blouses, and lingerie.

Madras: a yarn-dyed check, striped or plaid fabric originally from Madras, India, used for shirts, pajamas, and dresses. Hand-woven Madras in unusual color effects is used for neckwear, hatbands, etc.

Marquisette: a sheer, soft fabric of leno construction, used for curtains, blouses, and evening dresses. This cloth is now made with nylon or rayon for glass curtains, evening dresses, and lingerie.

Monk's Cloth: a coarse, heavy, loosely woven basket-weave construction used for draperies and couch covers.

Muslin: a plain weave, medium-weight cloth, coarser and of lower count than percale, used for sheets, mattress covers, and apparel. A typical construction in muslin is 64 x 64, 64 square, meaning 64 yarns are used in the warp and an equal number in the filling.

Nainsook: a semisheer of plain weave, soft fabric, heavier than batiste, and softer than organdy, used for blouses and infant's wear.

Organdy: a sheer, starched, plain weave fabric, used for dresses, curtains, and bedspreads. A permanent finish organdy retains its crispness after washing.

Osnaburg: an inexpensive plain weave heavy fabric with small flecks of cotton stalks remaining, used for sacking, also bedspreads and curtains.

Oxford Cloth: a soft shirting woven in a basket weave, generally solid color but also in stripe effects, used for shirts and sports clothing.

Pajama Checks: an inexpensive low-count medium-weight fabric with small checks made by weaving several warp or filling yarns together, used for men's underwear.

Percale: a plain weave medium-weight fabric of finer texture and count than muslin (80 by 80 is a typical construction), used for shirts, dresses, sheets, and sports wear.

Piqué: fabric of medium-weight having lengthwise cords or novelty honeycomb texture, used for dresses, men's shirts and sports wear.

Plissé: a plain weave fabric, solid color or printed, having an all-over puckered surface produced by chemical means. It is used for underwear, housecoats, and play clothes, and does not require ironing.

Poplin: a coarse broadcloth used for shirts, pajamas, and dresses.

Sateen: a cotton satin made with filling floats that produce a lustrous surface, used for draperies, bedspreads, and linings.

Seersucker: cloth with a permanent wrinkle effect produced by uneven tension in the warp yarns. Generally produced in colored stripes, and used for summer suits and sports wear.

Shantung: a cotton cloth similar to broadcloth with uneven slub filling yarns, used for dresses and children's wear.

Suiting: cotton or linen fabrics, heavier in weight than dress fabrics, generally made to resemble wool or worsted suitings in herringbone or twill weaves.

Swiss, Dotted: a sheer, crisp fabric covered with dots either woven or chemically applied, used for dresses, aprons, and curtains.

Terry Cloth: a looped pile fabric in a variety of patterns, used for toweling, rugs, and beach robes.

Theatrical Gauze: a plain weave open fabric made in linen, used for draperies and stage sets.

Ticking: tightly woven striped twill fabric of medium weight, used for mattress and pillow coverings and sports wear.

Velveteen: a cotton velvet, having short closely packed cut pile, used for dresses, coats, draperies, and upholstery.

Voile: a plain weave, two-ply fabric, semisheer, used for dresses, blouses, and curtains.

### SILK AND RAYON FABRICS

Typical silk and rayon fabrics include the following:

Brocade: a medium-weight silk fabric with multicolor decorative design in Jacquard weave, used for drapery, upholstery, dress, and tie fabrics.

Broché: a brocade fabric resembling embroidery, having distinct face and reverse side with long floats on the reverse.

Chiffon: a silk sheer of gossamer lightness used for dresses and lingerie.

Crepe: a fabric of many varieties, depending on the kind of yarn used for warp and filling, the count, and finish. These textures include sheer semitransparent chiffon, a sheer plain weave; georgette, slightly heavier in weight with crepe yarns used in both directions, warp and filling; crepe-de-chine, medium-weight, made from a characteristic yarn from China, generally washable; flat crepe, similar to taffeta, a plain weave having very little creped effect; romaine, heavier in weight and less creped than georgette; Canton crepe, the heaviest of all silk crepes, with a noticeable crosswise ribbed effect; and satin crepe, a reversible satin with close face, having a high count, tightly woven. Other crepe constructions are made with fine worsted wool filling.

Foulard: a twill weave, medium-weight fabric, generally printed in small motifs, used chiefly for ties and dresses.

Lamé: any material woven with a metallic or simulated metallic yarn. Brocaded designs are frequently used to display a decorative pattern for evening wear. Nontarnishable and washable aluminum yarn of various colors is combined with cotton, wool, or rayon for street and sports wear.

Lastex: a yarn made from rubber, covered with silk, rayon, or cotton, used either interwoven or for a puckered effect obtained by stitching; popular for bathing suits and other sports wear.

Pongee: a plain weave, medium-weight fabric, having irregular yarns and the characteristic tan color of wild silk. Pongee is generally washable, used for dresses, blouses, sleeping garments, and curtains.

Satins: made with a long float on the surface in an irregular twill weave, producing a highly lustrous face. Various types of satins include a light-weight washable satin used for blouses and lingerie; crepe-back satin, panne satin, high polished in the finishing; slipper satin, made with silk warp and cotton filling; ciré satin, a glossy finished satin, used for millinery in ribbon or broad goods.

Shantung: a plain weave fabric made in dress and suiting weights, with irregular nub yarns, not unlike pongee in texture and appearance.

Sharkskin: a heavy taffetalike rayon in suiting weights with a heavy crisp hand, used for sports wear and suits.

Silk Lace: a fragile and delicate type, made in various patterns, especially for veils and evening gowns. Silk and rayon are used for both hand-made and machine-made silk laces.

Surah: a twill weave silk or rayon fabric of fairly heavy weight, used for men's ties, women's tailored dresses and suits.

Taffeta: a plain weave, opaque silk fabric of medium-weight, used for ribbons, dress fabrics and draperies. Iridescent taffeta is made by using one color of yarn for the filling and another for the warp. The fabrics known as faille, grosgrain, bengaline, and gros de Londres are all variations of taffeta.

Tulle: a sheer transparent netlike fabric, used for veils and millinery.

Velvets: pile fabrics produced by interweaving through the warp and filling yarns a third set of yarns making the pile. Velvets are sometimes woven double and the pile cut after weaving. Others are made by having the pile looped around wires. Uncut velvet, like Brussels carpeting, has the pile in one continuous strand. The texture resembles a terry cloth towel. Velvets are made of various combinations of yarns with either a silk back and pile, as in all-silk velvet; a silk back with rayon pile, as a transparent velvet; and Lyon's type, medium to heavy weight, having an erect pile and stiff taffeta-like back. Chiffon velvet has a short, lustrous pile. Velour is similar to velvet with a long pile. Panne velvet has a lustrous surface produced by pressing the pile flat.

## WOOL AND WORSTED FABRICS

Typical wool and worsted fabrics include the following:

Albatross: a light-weight, soft, fine quality worsted cloth similar to sheer crepe, but having a more pronounced texture than challis; used for blouses, dresses, scarfs, and children's clothing.

Astrakhan: a coating made to imitate the fleece of the astrakhan or Persian lamb; a pile cloth with a distinctive curled finish.

Baby Flannel: a light-weight plain or twill weave washable flannel for blankets and infants' robes.

Barathea: originally a tie silk, with a pronounced broken filling effect, used for men's evening wear in fine worsted, now made in women's suiting and coating.

Basketweave: a loose-textured fabric having two or more yarns woven together, resembling basket work. Sometimes a bouclé yarn is used to obtain this effect.

Bedford Cord: a clear-finish worsted cloth, having longitudinal cords used for coatings, suitings, riding habits, and uniforms. It is a hard-finish, long wearing and durable cloth. The cord effects may be in different widths. Cotton piqué is made in a similar construction.

Bird's Eye: a clear-finish worsted suiting, marked by small woven indentations resembling the eye of a bird.

Blanket: the experimental fabrics woven by a mill in producing new color effects. Blanket cloth used for women's coats, generally woolen, is heavily napped and fulled.

Bouclé: from the French meaning "buckle" or ringlet; any cloth made from looped yarns.

Broadcloth: a napped and polished face-finish coating and suiting, generally in a twill weave.

Brushed Wool: any woven or knitted cloth that has been finished by being napped or teaseled. Coatings are made with long, shaggy effects.

Camel's Hair: dress fabric, suiting, or coating cloth or knitted goods made from the fibers obtained from the camel; the cloth used for polo coats, distinctive in color. A napped woolen is a favorite with American women.

Cashmere: cloth made from the downy fiber from the Cashmere goat. Light in weight, yet exceedingly warm, the material is rare and expensive.

Cassimere: medium-quality suiting, frequently in herringbone weave and made from a combination of wool and worsted yarns.

Cavalry Twill: a durable steep twill showing a double diagonal stripe; also known as élastique, used for army uniforms, as well as coatings and suitings.

Challis: a plain weave, light-weight woolen or worsted cloth, in solid color or printed in distinctive motifs, used for children's wear, dresses, blouses, robes, and scarfs.

Check: a pattern of regular woven squares, such as Shepherd's check, pin check, etc.

Cheviot: a suiting and overcoating made in a twill weave, closely woven, originally from wool from the Cheviot Hills in Scotland; made with stock-dyed or piece-dyed yarns, ideal for casual wear.

Chiffon: originally a silk sheer of gossamer lightness, but also a term meaning light in weight, as a chiffon worsted.

Chinchilla: a type of fur and also a coating made with a twisted curled pile; a durable, attractive cloth for children's coats and sports wear.

Chlorinated Wool: a treatment in the finishing of wool which decreases shrinkage.

Covert: a coating fabric with a steep twill in either worsted or woolen yarns. Generally two colors are used in the warp. Originally the fabric was used for hunting jackets, but now is considered desirable for both town and country wear.

Cravenette: a registered trade-mark name for a water-repellent finish used for rainwear.

Crepe: a worsted, light-weight dress goods made with tightly twisted yarns, generally having a clear finish. Crepe woolen, heavier weight cloth, also crinkled, used for coatings and suitings.

Cross-dyed Cloth: generally a material made with wool and silk, rayon, or cotton yarns that produce a contrasting color effect when dyed.

Diagonal: a twill weave cloth with a pronounced diagonal stripe. Generally twill weaves run from lower left to upper right on an angle of 45, 63, 70, or 75 degrees. A herringbone is a reverse twill.

Dobby: any cloth having a small woven motif in check, dot, square, or lozenge.

Doeskin: a finish used on suitings and coatings, producing a soft, slight nap, and a smooth face. Doeskin finish is used on various types of constructions. The nap is shorter and more compact and used for fleece-type coatings. The appearance resembles duvetyn, a napped spun-silk fabric with a close face. During pioneer days in America, real buckskin or doeskin was used for men's trousers and jackets.

Donegal: a type of tweed-like fabric generally made with

white wool, colored filling, and pronounced nubs in bright colors; it is usually woven in herringbone, but it also appears in plain weave. It is available in dress, suiting, and coating weights.

Dress Worsted: fine quality, face-finished suitings originally made for men's evening clothes, but now used for women's town and afternoon suits and coats, as distinguished from sports wear and casual fabrics.

Élastique: *see* Cavalry Twill.

Éponge: meaning spongy, generally a plain weave cloth loosely woven of soft novelty yarns.

Face-finished Fabric: coatings and suitings napped and otherwise treated to obtain a distinctive effect in contrast to clear-finished fabrics, which reveal the weave clearly. Face-finished fabrics include chinchilla, unfinished worsteds, fleece, saxony, and broadcloth.

Faille: a plain-weave fabric with heavy filling yarns that produce a cross-ribbed effect; generally made in silk or rayon yarns, but now available in all-worsted yarns for dress and suitings.

Fancy: any novelty-woven or textured fabric that does not conform to a recognized standard construction.

Felt: matted, compact material made with heat and pressure, causing woolen fibers to be interlocked into a firm opaque mass. Fine quality felts are also blended with beaver or rabbit fur. It is used for hats, women's sports wear, table coverings, etc. Cotton felt is made in very cheap grades.

Flannel: a twill weave wool-worsted or combination fabric made in various weights, either in stock-dye or piece-dye with a slight napped finish.

Fleece: overcoating and topcoating made with a napped surface, generally from a woolen yarn in a twill weave. All kinds of fibers are used, such as camel's hair, fine wool, and mixtures.

Fur Fabrics: materials made from yarns in which a certain percentage of beaver, rabbit, mink, or other fur fibers is used for a distinctive color and texture effect.

Gabardine: a twill-weave clear-faced worsted cloth made in a variety of weights from 8 to 16 oz. The yarns are tightly twisted, and the twill is generally at 63 or 70 degrees and shows a different appearance on the reverse side; one of the most costly, yet most popular, of worsted fabrics; the construction is copied in other kinds of yarns.

Granite Cloth: an irregular pebbled weave used in dress crepes and suitings; a variation of the plain weave.

Gun Club Checks: sports wear fabrics with three colors of yarn used in warp and filling, regularly spaced as 6 and 6 in each color, both warp and filling.

Heather Mixture: named for a small white-pink or bluish-pink flower from the Scottish highlands; multicolor effects in cloth, as blue and lavender, resembling the attractive appearance of the flower.

Herringbone: in weave, a reverse twill; also descriptive of sports wear fabrics, dress, suitings or coatings, either wool or worsted, which are generally yarn-dyed and given a natural finish.

Homespun: originally cloth made from yarns spun by housewives, generally irregular and coarse. Homespun fabric is generally rugged and sturdy in character, used for sports wear. Tweeds are of the same classification.

Honeycomb or Waffle Cloth: a novelty raised effect produced with an unusual arrangement of warp and filling, resembling the distinctive cellular comb of the honey bee or the iron form used for making waffles.

Jacquard: any fabric woven with a large decorative design, regardless of fiber content.

Jersey: a knitted cloth in plain stockinet or ribbed stitch, also the slipover sweater.

Kasha: a trade-mark name for a twill-weave woolen fabric decorated with dark goat hairs.

London-shrunk: a type of finish used on worsteds in which the cloth is subjected to both hot and cold water, steam and pressure. The finish removes excess shrinkage.

Melton: an overcoating in quality yarns that resembles a heavy, dull-finished broadcloth. It is tightly woven, and the finish is napped, then sheared.

Merino: fine-quality worsted wool.

Metallic Cloth: any fabric woven or knitted with metal, gold, silver, or aluminum, yarns or simulated metal. Originally real gold was used for luxurious cloths for ecclesiastical vestments and altar hangings. Aluminum yarns are now used with wool or worsted yarns, both woven and knitted, for dresses, coats, and suits.

Mohair: cloth made from the hair of the angora goat; popular for tropical worsteds, and also used for upholstery.

Nap and Napped Fabric: the finish used in fabrics produced by raising the surface of protruding fibers to gain additional warmth. Typical napped fabrics include fleece, coatings, so-called unfinished worsteds, and blanket cloth.

Nun's Veiling: a sheer, light-weight, worsted fabric in plain weave, generally of a solid color, especially woven for religious dress, but sometimes used for dress goods.

Overplaid: a distinctive plaid effect that appears to be a double plaid; a large open-work plaid covering a small check. The Glen Urquhart is typical.

Oxford Cloth: fabric made from a mixture of black and white yarns which produces various effects in light or dark greys. The fiber is blended in the stock.

Palm Beach: a trade-marked summer-weight suiting generally containing mohair yarn. Tropical worsted is a light-weight cloth, in plain or twill weave, made of worsted yarns. Because of its popularity, it has been copied in less expensive yarns, which must be identified.

Rabbit Hair: rabbit fur which is sometimes combined with wool and worsted fabrics to produce a soft, lustrous finish, particularly desirable for dress goods.

Ratiné: cloth made from curled yarns similar to bouclé.

Saxony: high-grade wool produced in Germany, popular in suiting and coating weights, made in herringbone or twill weaves, or resembling tweed.

Serge: a closely-woven, clear-finished worsted cloth having a 2 up and 2 down 45-degree twill, one of the most durable of all worsted fabrics, noted for long wear. It is usually piece-dyed and made in all weights. Blue is the favorite color.

Sharkskin: a tighty-woven worsted fabric with a small, indistinct color effect produced with both warp and filling of contrasting colors. Rayon sharkskin is a plain-weave heavy cloth with an irregular surface.

Shepherd's Check: a small, all-over regular checked effect in dark color with white, generally worsted with four black alternating with four white yarns, both warp and fillingwise.

Shoddy: remanufactured wool obtained from worn garments pulled apart by a garnetting machine. Generally shoddy contains both wool and cotton yarns.

Velour: a napped finish used for felt of fine quality; also a closely-napped, soft, tightly-woven wool fabric of fine quality. This is a face-finished cloth used for luxurious coatings.

Venetian: a closely-woven, steep twill, lustrous fabric, generally used for suitings and coatings, said to be originally from Venice, which excelled in the production of fine quality cloth.

VICUÑA: fibers from the vicuña, an animal living in the high mountains of Peru, Bolivia, and Ecuador. The fibers are exceedingly fine and soft, strong, resilient, and golden chestnut to rich fawn in color; one of the most costly fibers used in the textile market.

VIRGIN WOOL: new or unused wool, as distinguished from reworked or reprocessed wool.

WOOL: fibers from the fleece of the sheep and animals of the so-called specialty fiber group, including the angora and cashmere goat, the camel, llama, and vicuña.

WOOL PRODUCTS: any cloth containing wool either new, reprocessed, or reused, that must be clearly identified as to content.

WORSTED: cloth made from long-staple choice stock, closely woven; used as dress fabrics, suitings and coatings. The finish may be either clear, natural, or face-finished. It is one of the most durable and attractive of all wool fabrics. *See also* CELLULOSE; COTTON; DYES, TEXTILE; FLAX; SILKWORM; SYNTHETIC FIBERS; WOOL. B. G. C.

**THACKERAY, WILLIAM MAKEPEACE** [thæ'kəri] (1811-1863), English novelist, was born July 18, 1811, at Calcutta, India. His father, a wealthy official, died four years later, and in 1817 the boy was sent to England to be educated. Loneliness and the rough conditions of boarding schools soon caused him to mask his sensitive feelings with comedy and sarcasm. At Charterhouse School, London, from 1822 to 1828, he was too lazy to study hard, but became popular for comic drawings and verses. He attended Trinity College, Cambridge, for more than a year, but had no clear plans for a profession and seized the first excuse to withdraw.

After some months in Germany he began legal studies in London; but when he came of age and inherited his patrimony he went to Paris as an art student. Extravagant habits and card-playing were eating into his funds, and he lost money by buying and editing a literary weekly, *The National Standard,* which failed in less than a year. Finding that he was unlikely to become a good painter, he made efforts to get commissions as an illustrator of books, and began to write sketches for magazines. In August, 1836, he married seventeen-year-old Isabella Shawe. At this time he became Paris correspondent for *The Constitutional,* a new Liberal daily in which his stepfather was a shareholder. Later for a short while he was managing editor, but in June 1837, the paper collapsed, financially ruining Thackeray.

As a book reviewer for *The Times* and a contributor of humorous tales and essays to *Fraser's Magazine* and other periodicals, Thackeray contrived to earn a living, but no literary reputation, as his identity was concealed under such pen-names as Charles James Yellowplush, Major Goliah Gahagan, and Michael Angelo Titmarsh. A pirated edition of his *Yellowplush Correspondence* was printed in Philadelphia in 1838. His first book of any size was *The Paris Sketch Book* (1840), soon followed by *Comic Tales and Sketches.* Both were collections of his magazine contributions, illustrated with his own drawings.

Three daughters had been born between 1838 and 1840, the second dying in infancy. After the birth of the third, Mrs. Thackeray developed mental illness, and had to be kept under restraint for the fifty-four years which remained of her life. About this time Thackeray had attempted longer works of fiction as serials in *Fraser's Magazine,* but both *A Shabby Genteel Story* and *The Great Hoggarty Diamond* were handicapped by his family troubles. In 1842 he toured Ireland to get material for *The Irish Sketch Book,* a pleasant travel book, which was followed by *From Cornhill to Grand Cairo* (1846), a similar record of a trip to the Near East. Both books showed impartiality and good sense on controversial issues.

From 1842 onward he was a regular contributor to the recently-founded comic weekly *Punch,* winning particular success with *The Snobs of England* and *Punch's Prize Novelists* (parodies of contemporaries). By these latter, as well as by outspoken criticisms of books and art exhibitions, he made some enemies through his indiscreet satire. Though still unknown to the general public, he was by now a familiar figure among the journalists and hack writers. Humorous poems in *Punch* showed another side of his talents. A historical novel, *Barry Lyndon,* appeared in *Fraser's* during 1844; and in January, 1847, he began to publish in monthly installments his first long novel, *Vanity Fair,* which soon caused him to be bracketed with Dickens as the leading novelist of the day. While some readers complained that he was digressive and cynical, others admired his easy, unpretentious style, his wide knowledge of upper-class life in England and on the Continent, his satiric wit, and his sudden bursts of sympathy.

Burdened with the support of his wife and young children, and aware of permanent impairment of his health, he became obsessed with a determination to earn money equivalent to the inheritance he had lost. Living irregularly in clubs and lodgings, eating and drinking unwisely, he found his chief happiness and encouragement in the friendship of two persons—a college comrade, W. H. Brookfield, and Brookfield's beautiful wife. The success of *Vanity Fair* enabled him to establish a home for his daughters and made him popular in London society. He enjoyed aristocratic circles so frankly that some colleagues accused him of snobbishness.

His second novel, *Pendennis* (1848-1850), was largely based on his own early career. In hope of further profit from his new fame, he undertook a series of public lectures on *The English Humorists,* which he delivered successfully throughout England and Scotland, though he suffered torments before an audience. His next book, *Henry Esmond* (1852), a historical romance, was tinged with melancholy arising from complications in his relations with the Brookfields.

The winter of 1852-1853 was spent in a lecture tour of the United States, where he was happy and made many friends. Upon his return to England he wrote *The Newcomes,* another novel embodying family and personal experiences. On a more extensive American tour in 1855 his lecture topic was *The Four Georges,* and he later gave these lectures widely in his own country.

Suffering increasing pain from his chronic ailment, and always hoping to escape from the drudgery of authorship, he applied at various times for appointment in the postal department, in the foreign service, and as a London magistrate. In 1857 he was Liberal candidate for the House of Commons at an election at Oxford, and was narrowly defeated.

*The Virginians* (1857-1859), his last long novel, was a sequel to *Henry Esmond.* In 1860 he became the first editor of *The Cornhill Magazine,* and its success brought the full prosperity he had long sought. Two short novels, published serially in the magazine, showed a decline in his powers, and he was happier in a monthly series of informal essays, *The Roundabout Papers.* After two years he resigned the editorship and applied himself to another historical novel, *Denis Duval.* It was unfinished at his death, which occurred Dec. 24, 1863. *See also* HENRY ESMOND; NEWCOMES, THE; PENDENNIS; VANITY FAIR; VIRGINIANS, THE. L. St.

**THAILAND.** *See* Siam.

**THAÏS** [ta·i's], a French historical and philosophical novel by Anatole France (1844-1924), published in 1890. It retells in a graceful and poetic style the legend of the conversion of the famous courtesan of Alexandria, Thaïs, by the desert monk, Paphnutius. At the end of the novel she retires from the world to become a hermit saint in the desert. Both parties to the conversion had been deluded: Thaïs had mistaken a promise of eternal salvation for one of eternal beauty, while Paphnutius discovered that he had been more interested in the beauty of Thaïs' body than in that of her soul.

The symposium in the famous banquet scene at the home of Thaïs presents the views of the various schools of philosophy in Alexandria in their clash with Christianity, the Christian faith being represented in the person of the ignorant monk, Paphnutius. France's own skepticism and his dislike of Christian asceticism permeate the discussion. Both critics and scholars have praised the accuracy of the novel's evocation of the historical period, and it has also been the most widely read of France's works. The libretto of Massenet's opera *Thaïs* is based upon the novel. J. F. M.

**THAKUR.** *See* Asiatic Tribes (*Indo-Iranian*).
**THALAMUS.** *See* Brain.

**THALES** [the'liz] (c. 624-546 B.C.), Greek philosopher and founder of the Ionian school, was born in Miletus in the latter half of the seventh century B.C., perhaps of Phoenician stock. He is known as the father of Greek philosophy and was numbered among the Seven Wise Men of Greece. Thales achieved fame as an astronomer for predicting an eclipse of the sun calculated to have occurred in May 585 B.C. He was also an able statesman and tried to unite the Ionian cities in a defensive confederacy against the Persians. A military engineer in the service of Croesus, he is said to have diverted the course of the Halys River, and as an astute man of affairs, he at one time established a monopoly in olive oil. Tradition claims that he introduced abstract geometry, knowledge of which he had acquired during a stay in Egypt, to the Hellenic world.

No authentic writings of Thales are extant, and knowledge of his doctrines is based entirely on secondary sources, especially on the account given by Aristotle (*Metaphysics* I, 3). Thales asserted that water was the origin of all things, that is, that it was that out of which everything arose and into which everything resolved itself, basing his inference, according to the conjectures of Aristotle, on the observation that many elements essential to life (nourishment, heat, seeds, and so forth) contained moisture. Aristotle also attributed to Thales the sayings that "all things are full of gods" and that "the magnet has a soul because it attracts iron." The general doctrine of animism inherent in Thales' philosophy—that is, the belief that matter is imbued with life and has a soul (sometimes termed hylozoism)—was a tenet common to all the earlier Ionians and does not necessarily imply that Thales believed in the existence of a world soul. Thales' claim to be the father of Western philosophy lies in the fact that he faced the problems of philosophical inquiry squarely, basing his conjectures on observations that were both scientific and methodical. C. W. D.

**THALIA.** *See* Graces; Muses.

**THALLIUM** [thæ'liəm], symbol Tl, atomic number 81, at. wt. 204.39, density 11.85, m.p. 303.5° C., b.p. 1,650° C. Thallium (Greek *thallos,* budding twig) is the last member of Group III-B of the periodic table. It closely resembles indium and gallium and is more distantly related to aluminum and boron. The atom of thallium has five completed shells of electrons (2, 8, 18, 32, 18) with an outer shell of three. It is a typical metal, with valences of 3 and 1. Thallium is a white metal with a bluish tint, soft enough to leave a mark on paper; it lacks ductility and elasticity, and is only slightly malleable. Its thallous compounds resemble the compounds of alkali metals; they are highly ionized in solution. The thallic salts are stable only in the presence of acids and are considerably hydrolyzed in solution. Thallium compounds are cumulative poisons and as such are used for exterminating rodents. B. S. H.

**THALLOPHYTES** [thæ'lofaits], one of the four main divisions of the plant world; this group embraces all of the flowerless plants that have no vascular system. The algae, fungi, and lichens, some of which are wholly microscopic, are included in the thallophytes; their method of reproduction is usually by spores, although some variations occur. These plants have no roots, leaves, or stems; the plant body is usually a thallus, the most familiar example of which is the seaweed. *See also* Algae; Fungi; Lichens. F. J. S.

**THAMES** [tɛ'mz], the principal river of England. It rises at Thames Head in the Cotswold Hills of Gloucestershire and follows a winding easterly course 209 mi. to the North Sea. The river is tidal up to Richmond, and the fall of 365 ft. to sea level is controlled by 44 locks, enabling barges to navigate as far as the junction of the River Colne at Lechlade in Gloucestershire. The Thames forms boundaries for Gloucestershire, Oxfordshire, Buckinghamshire, Middlesex, Essex, Wiltshire, Berkshire, Surrey, and Kent, and is believed originally to have formed part of a great river system reaching far into the western Midlands. There are nine main tributaries; the Colne, Leach, Windrush, Evenlode, Cherwell, Thame, Kennet, Wey, and Medway. Of the canals connecting the river with other waterways, the Grand Junction and the Union are the most important.

Scenically, the most beautiful reaches are between Oxford and Cliveden, near Windsor. Narrow from its head to Oxford, the Thames Valley widens to 21 mi. at Oxford, narrows to 1 mi. at Goring, then broadens into the great basin 100 mi. long and averaging 30 mi. wide, of which Greater London is the center. The estuary commences at Tilbury, and extends to the Nore lightship off Shoeburyness. In addition to London, the principal towns and cities on the banks are Oxford, Abingdon, Wallingford, Reading, Henley-on-Thames, Marlow, Maidenhead, Windsor, Staines, Kingston, Richmond, Greenwich, Gravesend, and Tilbury.

The use of the Thames is controlled by two official bodies, the Thames Conservancy Board, whose authority extends from the headwaters to Teddington, and the Port of London Authority, which controls the remainder. The conservancy board controls the navigation, use, and conservation of the river water, its pollution, flood prevention, and fishing, and is associated with the drainage board of the catchment area. B. Su.

**THAMYRIS** [thæ'mɪrɪs], in Greek mythology, a Thracian bard who presumptuously challenged the Muses in a contest of song. When defeated, he was deprived by them of his sight and of the power of singing. *See also* Muses. G. E. D.

**THANATOS** [thæ'nətɒs], in Greek mythology, the personification of death, the son of Night and brother of

Sleep (Hypnos, or Somnus). When Thanatos carried off Alcestis, Heracles forced him to give her up and return her to her husband Admetus. *See also* ALCESTIS. G. E. D.

**THANKSGIVING DAY.** *See* HOLIDAYS AND HOLY DAYS.

**THAR DESERT** or **INDIAN DESERT** [t·hʌr; tɑr], a desert 100,000 sq. mi. in area in northwestern India, between the Aravalli Range on the east, the Indus River on the west, the Sutlej River on the west and north, and the Gulf of Cutch and the Arabian Sea on the south. It is a sandy area with a few hills and waterless valleys and no vegetation except for a few patches of xerophytic plants. The rainfall is approximately 3 in. a year, increasing to 10 in. on the outer edge of the desert. The mean annual temperature is about 80° F., and during the summer daytime temperatures frequently reach 100° F. The desert cannot be irrigated because it is too far from the Indus River. Jaisalmer, one of the few towns in the desert, is the center of the camel routes across the heart of the desert. J. E. F.

**THÁSOS** [thɑ′sɔs; the′sɒs], the name of a Greek island and its chief town, in the northern part of the Aegean Sea, in northeast Greek Macedonia, 16 mi. southeast of Kaválla, and separated from the mainland by the Thásos Strait. It has an area of 170 sq. mi. The chief products of the island are olive oil, tobacco, maize, wine, honey, and timber; and there are marble quarries and fisheries.

The earliest known inhabitants of the island were the Phoenicians, attracted to Thásos by its valuable gold mines. They were led by Thásos, son of Phoenix, from whom the island derived its name. The island was afterward colonized by the Saians, a Thracian tribe, and in the eighth century B.C. by Greek settlers from Páros. The Greek colony rapidly rose in power and wealth and exploited the even richer mines on the adjoining mainland. In 492 B.C., Darius the Great compelled the Thasians to pull down their fortifications and to surrender their ships; and in 463 B.C. the Athenians, after a siege of two years, again exacted a heavy tribute and forced the Thasians to surrender their mainland possessions. After the battle of Aegospotamos in 405 B.C., Thásos passed into the possession of the Lacedaemonians. In the Roman wars in Greece, Thásos submitted to Philip V of Macedon, but received its freedom after the battle of Cynoscephalae (197 B.C.). The island was later held for a short time by the Venetians. The Turks conquered the island in 1462 and held it until 1912, when they were compelled to cede it to Greece. It is now a part of Kaválla District. The ancient city of Thásos on the north coast is now in ruins. Pop. 1951, 15,208. C. W. D.

**THATCH PALM,** common name of a genus, *Thrinax,* of small palms, natives of southern Florida, the West Indies, and Central America. Of about 10 species, four are found in dry and sandy places in southern Florida. The fan-shaped leaves are 2 to 4 ft. across, and are used widely for thatch and for making hats, baskets, and small cordage. The slender trunks, 20 to 30 ft. high, are used for piles in building small wharves. The wood is light and soft. J. C. Wis.

**THAYER, ABBOTT HANDERSON** (1849-1921), American painter and author, was born in Boston, Mass., Aug. 12, 1849. He studied at the National Academy of Design and later in Paris with Jean Léon Gérôme. Especially known for his idealized compositions of women and children, Thayer also painted landscapes and portraits in a wide variety of techniques. His many years of research on the subject of protective coloration in animals resulted in several publications. Thayer died in Monadnock, N. H., May 29, 1921. E. B. S.

**THEA** [thi′ə], in Greek mythology, a Titaness, daughter of Uranus and Gaea. Wedded to the Titan Hyperion, she became the mother of Helios and Selene. *See also* TITANS. G. E. D.

**THEATRE,** from the Greek verb *theasthai,* which means "to see," a place where dramatic performances are produced and viewed.

**Oriental.** All legends point to the fact that the theatre evolved from ritual festivals and dances. Here lie the roots of the passion and coronation plays of ancient Egypt. China has her Pear Garden legend, which connects the origin of her theatre with the worship of the moon. Japan knows of sacred dances before the Heavenly Cave of the Ancestral Goddess, and Brahma was prompted by divine guidance to invent the drama in India. In all oriental cultures two theatrical strains are easily distinguishable, the aristocratic and the popular. In either instance, the theatre of the East makes an appeal to the unlimited power of imagination. It is a suggestive theatre, its stage frankly presentational, making no attempt to be realistic. The actor's gestures are symbolic, his costumes, masks, or make-up conventional; his voice has an artificial quality, and his movements are controlled by the rhythm of music. Everything is tuned towards the creation of a highly stylized world of beauty, which guarantees the oriental mind an absolute escape into the realm of art, an experience rarely accorded to the occidental.

**Ancient Greece.** When the tyrant Pisistratus assumed power over Athens (561 B.C.), the Athenians celebrated a number of yearly festivals in honor of Dionysus. One of these festivals, the Great or City Dionysia, featured lyrical contests in which hymns in praise of the god (dithyrambs) were sung. Pisistratus decided to make dramatic performances (such as could be seen in the Icarian peasant theatre of Thespis) part of the Dionysus celebration. Thus he stimulated dramatic production and laid the foundation for the flowering of Greek drama in the fifth century, when, at each spring festival, three dramatists competed for the first prize in the annual dramatic contest. Each playwright entered the competition with three tragedies and one satyric

play. The management of the drama festivals lay in the hands of the Athenian chief magistrates, who, assisted by curators, chose the playwrights, appointed the choral producers (*choregi,* wealthy citizens who paid for the training and the costumes of the chorus), and engaged the actors. The Greek playwright was restricted in the number of actors at his disposal. Thespis is credited with setting up the first actor, who carried on a dialogue with the spokesman for the chorus. Aeschylus introduced the second actor, Sophocles the third. The early Greek dramatists were their own stage directors and supervised the chanting and dancing of their actors and chorus. Later, special coaches were in charge of the training of the chorus. Originally, the tragic chorus consisted of fifty members. Aeschylus reduced their number to twelve, and Sophocles increased it again to fifteen. The chorus in comedy consisted of twenty-four members. Aristotle gave Aeschylus credit for having invented the tragic costume.

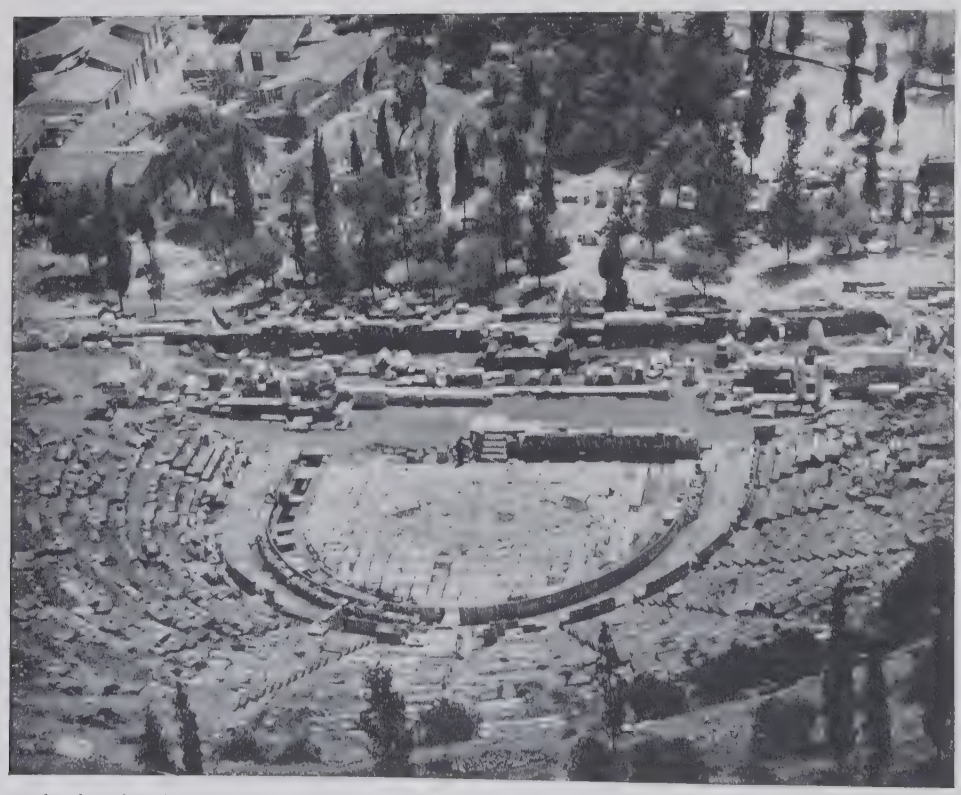
**Roman.** The stages upon which the plays of Plautus and Terence were originally performed were long wooden platforms erected for special occasions in the Forum or in the arena of a circus.

Plays could be seen in Rome only on festive occasions in connection with the games (*ludi*), which were a combination of circus games, theatrical performances, and variety shows. During the course of the Republic these games grew more and more numerous, and a Roman playwright therefore had many opportunities to see his plays produced. The official in charge of a particular game hired professional companies which were owned by managers to whom the playwright sold his plays. Thus, in contrast to the Greek theatre, the Roman theatre was frankly commercial. These professional acting companies performed not only in Rome but also toured the provinces, visiting those Italian cities which had games of their own and permanent theatres which were, in a number of instances, older than those of the capital.

The majority of Roman actors were slaves and regarded as nothing better than vagabonds. Not until the art of acting reached its height in the first century B.C. was it possible for a prominent actor to acquire social prestige, such as was attained by the great comedian Quintus Roscius and the no-less-famous contemporary tragedian, Clodius Aesopus. Both actors acquired huge fortunes and trained their own students. It is probable Roscius introduced the mask on the Roman stage, and we gather from Cicero that the older generation did not particularly care for this innovation. In the original performances of the plays of Plautus and Terence the actors seem to have used make-up instead of masks. Women's parts on the stage of the Roman Republic were played by men. Under the emperors the interest in comedy



*THE THEATRE OF DIONYSIUS SEEN FROM THE ACROPOLIS*

CHARLES PHELPS CUSHING

and tragedy declined. The chief interest of the Romans was focused on the sensations of the circus, and in order to be able to compete with the spectacles in the amphitheatre, the stage also had to strive for sensationalism. Circus elements invaded the legitimate theatre. Animals, chariots, and armies of supernumeraries represented the empty splendor that attracted the masses, and the pantomimes of Bathyllus and Pylades tickled the palates of the connoisseurs.

**The Middle Ages.** The earliest medieval drama, the liturgical drama, was performed in the church itself. As secular elements, such as humorous incidents and prankish devils, forced themselves into the religious plays, the plays had to leave the church and were produced in front of it (Adam Play) and still later in market squares (Lucerne and Frankfort Passion Plays). The medieval stages were multiple stages; i.e., the various localities required in the play were represented simultaneously on the stage. These independent scenic units are known as mansions, e.g., Paradise, Hell, and Purgatory mansions. In the case of processional plays, such as flourished in England (York, Chester, and Coventry), Italy (Florence and Milan), and Spain (in all major cities in connection with the Corpus Christi festival), itinerant stages and pageant-cars rolled through the principal streets of the city and halted at predetermined points, where a scene of the (usually cyclical) play was enacted. The responsibility for the equipment of these pageants was in the hands of the local guilds, with the result that the performance of a mystery play became the affair of the entire community. Royalty attended the performances, and with them arrived the swarms of courtiers. The clergy, high and low, were always in the foreground, while the middle class and the country folk made up the colorful background for these true festivals of the people. During the later Middle Ages the mystery plays (liturgical dramas) grew more and more spectacular and sensational. There was a growing interest in the techniques of Biblical tortures and executions, an interest, however, which at no time precluded a most tender feeling and the flow of tears at the sight of the sufferings of Christ and the martyrs. For the medieval populace the religious drama was a most exciting and stirring reality.

**The Renaissance.** The Renaissance theatres were modifications of the theatres of antiquity. Information concerning the ancient playhouses was obtained by Italian architects from a treatise, *On Architecture,* which the Roman architect Vitruvius Pollio wrote in the time of Augustus. At the end of the fifteenth century, Vitruvius' study was rediscovered, and the story of the Renaissance theatre is a compromise between classical ideas, inherited from Vitruvius, and the overwhelming interest in the new art of perspective painting.

**Improvised Italian Comedy.** The term *commedia dell' arte* (also the older terms *commedia a soggetto* and *commedia all'improviso*) refers to the improvised comedy which flourished in Italy during the sixteenth, seventeenth, and eighteenth centuries. Leaving aside the highly controversial subject of the origins of improvised comedy, we can turn to certain features of the *commedia dell'arte* which had become standardized by the end of the sixteenth century. First, the characters were conventionalized to such an extent that we can distinguish certain stock personages who, under a variety of names and with certain local modifications, were seen again and again on the stages of the strolling players. Such stock characters were Pantalone, the doctor, the captain, the clowns (as a rule, two, one extremely clever, the other a booby), the young lovers, and the maidservant. Not only the types became standardized, but also their speeches and comic business. It would be wrong to assume that Italian improvised comedy was all improvisation. Each player was supposed to have at his or her command a sufficient amount of premeditated material, stock speeches in character, for instance, which could be used wherever the basic scenario (*soggetto*) required it. The impromptu players were, under the management of a *capocomico,* organized into traveling companies. Such major troupes as the Gelosi and Fedeli enjoyed the backing of aristocratic patrons, among them the Dukes of Parma, Mantua, and Modena, in whose castles they often had opportunity to perform. The minor companies, unrecorded by history, moved from town to town and erected their primitive trestle stages in the central squares for the entertainment of the populace. While the major companies had at their disposal the paraphernalia of courtly stages, the minor ones had to perform with a minimum of costumes before a crudely painted backdrop.

**Tudor England.** From the beginning of the sixteenth century the English mystery cycles fell into increasing disuse, as a result of the Reformation, the impact of the Renaissance, and the distintegration of the guild system. But part of the medieval heritage lived on in farces and morality plays, which were performed by strolling players in the yards of the carriers' inns. These early inn-yard playhouses became the model for the first London playhouse, The Theatre, built at Shoreditch, just outside London, by James Burbage in 1576. And as one playhouse after the other was built in and around London—the Curtain, the Rose, the Swan, the Globe, and the Fortune—they followed with minor changes the pattern which Burbage had set. English actors had finally achieved legal status (1572), provided they were organized into companies under the license of an aristocratic patron. Elizabethan acting companies were business organizations in which the guild system—with its masters, hired men, and apprentices—prevailed. The apprentices, attached to the full-fledged master members of the company, played the female parts. The hired men, receiving weekly wages, had to play minor roles and work backstage as propertymen or prompters. The full-fledged actors were shareholders in the company. They were cast along "type" lines. There were specialists for clowns, for distinguished gentlemen, for notorious villains, and for the young gallants. Shakespeare himself seems to have played the old men, their smaller parts giving him an opportunity to see to his duties as a stage director. He wrote his title parts for Richard Burbage, the star of the Lord Chamberlain's Men, later the King's Men. In the rival troupe of the Admiral's Men, Edward Alleyn held the corresponding position, most successfully in the title parts of Marlowe's plays. The acting style of the great Elizabethan actors must have been a formal or stylized one, and their gestures were of a conventional rather than realistic nature. Indeed, conventional was the whole production style on a platform stage that was on almost three sides surrounded by the spectators standing in the yard.

**Restoration in England.** The Restoration theatre was shaped by two companies, the Duke of York's Players and the King's Servants. The first was managed by Sir William Davenant, the second by Thomas Killigrew, courtiers of Charles II to whom he granted a monopoly for theatrical productions. The Duke's company played in the Duke's Theatre, first at Lincoln's Inn Field, later in Dorset Garden, London; the King's company's home was the Theatre Royal in Drury Lane. In 1682, the two companies merged into one, a union which lasted until 1695. Most prominent among the Duke's players were Thomas Betterton and Mrs. Eliza-

beth Barry, while Killigrew offered such players as Charles Hart, John Lacy, and the captivating Nell Gwyn. Regarding the use of costumes, only such characters as Falstaff and Richard III were dressed in the Elizabethan style, while the majority of characters, Hamlet among them, wore the fashionable dress of the day. Classical or oriental characters

*SIR WILLIAM DAVENANT*

CULVER SERVICE

were garbed in fanciful costumes. Nor was there any pretense to historical accuracy in the costumes exhibited by the actresses who, as Cleopatra or Portia, looked at their best in the elaborate dresses of the Stuart court. Only for the sake of travesty did Restoration players dress in character, and Nell Gwyn was always successful when she did so.

**Classical France.** Classical French drama was cradled in buildings that resembled tennis courts. In this group belong the two rival houses of the seventeenth century, the Hôtel de Bourgogne and the Marais Théâtre (where the première of Corneille's *Le Cid* took place in 1637). During the first third of the century, various itinerant companies occupied these theatres for a while. By the middle of the century two permanent companies were associated with these two playhouses, which received brisk competition from a company headed by Molière (Jean Baptiste Poquelin), who from 1658 to 1673 played in the Petit-Bourbon and the Palais-Royal theatres in Paris. In 1680, all French troupes were united into one French company by a royal decree, which is generally considered the birth certificate of the Comédie Française. While lavish *mise-en-scène* was bestowed upon the production of opera, French legitimate drama, subject to the rule of the unity of place, required only a minimum of scenery. The revolt against this scenic dearth in spoken drama came in the eighteenth century, when Voltaire clamored for more spectacle and the removal of the spectators from the stage. The latter were banned from the stage of the Comédie Française in 1759, and from then on there was an ever-increasing demand for more scenic illusion. Denis Diderot, encyclopedist and philosopher, and Pierre Augustin Caron de Beaumarchais, dramatist, author of *Le Barbier de Séville* and *Le Mariage de Figaro,* took up the pre-Revolutionary fight for a theatre that was to be closer to everyday life. They anticipated the drawing-room atmosphere which, a century later, was to become the standard scenery for the naturalistic playwrights. The French Revolution abolished the monopoly of the Comédie Française, and scores of new theatres were opened, in fact so many that Napoleon had to restrict their numbers in 1807, when four principal playhouses were licensed and four secondary ones, the latter limited to the productions of vaudeville and melodrama.

**Eighteenth-Century England.** During the eighteenth century two major theatres were built in London. In 1705, the Haymarket Theatre was opened. Originally destined to be the home of the Duke's company, it became in 1710 the permanent home of opera. In 1732 the Covent Garden Theatre was built. Covent Garden and Drury Lane were designated as the two patent theatres, which had the exclusive right for the production of legitimate drama. There were a few minor houses which, in contrast to the two major ones, were forced to specialize in the field of musical satire. It was on the stage of one of these minor theatres that David Garrick (1717-1779) made his London debut. The emergence of Garrick in 1741 marked a milestone in English theatre history, and there is justification in dividing the eighteenth century into three periods, the pre-Garrick era (from the death of Betterton in 1710 to the appearance of Garrick), the Garrick epoch (until his retirement in 1776), and the post-Garrick period. As an actor, Garrick strove for greater naturalness, which contrasted sharply with the pseudo-classical style in which Barton Booth and James Quin had employed in the pre-Garrick era. Nor did Garrick stand alone; his rival, Charles Macklin, had likewise embarked upon a course of greater truthfulness to nature. As a manager, Garrick introduced a series of reforms. In 1763, he barred the spectators from the Drury Lane stage (as had Voltaire in France in 1759) thus doing away with a convention that had been accepted on the English stage since the days of Elizabeth. The removal of the spectators from the acting area opened the path for greater

*CHARLES MACKLIN*

FROM AN ENGRAVING BY W. READ

CULVER SERVICE

realism in acting. Another of Garrick's reforms concerned the lighting of the stage. He had the chandeliers removed in 1765 that until then had illuminated not only interior scenes, but exteriors as well. From then on, the chief sources of light were the candles (or oil lamps) which were placed behind the wings in front of reflectors. Footlights were probably used from the early days of the Restoration. The reform of lighting was but another step towards realism. The stage was now free for the painter, who was to revive the forgotten craft of perspective scene painting, and for the mechanical devices for "transformation" scenes and atmospheric effects.

**Early American.** The beginnings are rather hazy, and it is hard to draw a line between amateur and professional play-producing activities. But Williamsburg, Va., Charleston, S. C. (the Theatre in Dock Street, 1736), New York, and Philadelphia, Pa., were the early focal points. The first

colonial acting company of any stature was that of Thomas Kean and Walter Murray, playing in converted warehouses and public halls in Philadelphia and New York. But this Virginia Company of Comedians was soon to be overshadowed by Lewis Hallam's company, which arrived from London in 1752. After Hallam's death, his widow with her second husband, David Douglass, carried on the fight of the American Company against Puritan intolerance. Douglass built the Southwark Theatre in Philadelphia (1766) and the John Street Theatre in New York (1767). After the Revolution, Lewis Hallam, Jr., was old enough to look after the affairs of the company which, in 1791, had to face the dangerous competition of a rival troupe, organized by Thomas Wignell, the builder of the Chestnut Street Theatre in Philadelphia (1794). The American Company met the challenge by erecting the Park Theatre (1798), which was to become the outstanding theatre of New York for the next fifty years. By the end of the eighteenth century even Boston had two playhouses, the Federal Street Theatre (1794) and the Haymarket (1796).

CULVER SERVICE

**Towards Realism.** The two major English houses, Drury Lane and Covent Garden, had the monopoly for the production of legitimate drama in London until 1843, when, through the Theatre Regulation Act, freedom of the theatres was granted. This made it possible for managers like Samuel Phelps (Sadler's Wells) and Charles Kean (the Princess's Theatre) to stage their pretty Shakespearean revivals. On the stage itself, realism made steady progress. While the apron was in process of shrinking, the actors withdrew behind the proscenium frame; and the proscenium doors, which had formed the background for many a grandiose gesture of Mrs. Siddons, were abolished. Gas lighting was introduced in 1817-1818. There was also progress in the field of stage management. In 1831, Madame Vestris became manageress of the Olympic Theatre, where she advocated drawing-room realism in scenery and did away with the grotesque in burletta costumes and acting. In association with her husband, Charles James Matthews, she had a production style ready for a new English comedy of manners, which failed to appear. More successful in this respect was Marie Wilton (later Lady Bancroft), who managed the Prince of Wales's Theatre and discovered T. W. Robertson, whose "cup and saucer" comedy flourished under the Bancrofts. When they gave their last performance at the Prince of Wales's, the first translations of Ibsen's plays began to circulate in London, although Victorian society was not yet ready for the shock, and the Norwegian "dynamite" had to be handled in private performances.

**Naturalism.** Theatrical history was made one night in March, 1887, when, in a small wooden hall on Montmartre, Paris, André Antoine, in daytime a clerk in the gas company, opened his Théâtre Libre in protest against the conservatism of the Comédie Française and in defiance of the mercenary boulevard theatres and their well-made plays. Antoine had been inspired by Emile Zola and other apostles of naturalism, and while he was unable to carry out all the principles of naturalistic production on the first stage of his Théâtre Libre, he dreamed up a playhouse which would meet the requirements of the new art. It would be a playhouse of perfect scenic illusion, with no footlights and with actors oblivious of the timeworn stagy attitudes. One year later, Konstantin Stanislavsky returned to Russia from Paris and, disgusted with the staleness of Russian theatrical life, dreamed the very same dream. Stanislavsky (in association with Vladimir Nemirovich-Danchenko) finally realized his naturalistic ambition when the Moscow Art Theatre opened its doors in 1898, and each new play by Chekhov became for its director another stepping stone towards the final goal—the truth in the theatre. Antoine's Théâtre Libre had found imitators all over Europe; in Berlin a Free Stage had been launched in 1889 by Otto Brahm and nine other intellectuals, who deplored the fact that the economic expansion following the Franco-Prussian War of 1870-1871 had not been accompanied by any artistic advance. In 1894, Brahm became the manager of the Berlin Deutsches Theater, where he continued to stage plays by Henrik Ibsen and Gerhart Hauptmann in a naturalistic fashion. As a director, Brahm saw his goal in a psychological interpretation of character. Like Antoine and Stanislavsky, he asked of his actors moderation, restraint, and simplicity as well as complete submission to the ensemble idea. Scenically he followed to the letter the lengthy stage directions in which the naturalistic playwrights habitually indulged. He saw in shabby interiors a perfect expression of the dreariness of everyday life.

**Continental Impressionism.** At the turn of the twentieth century, the naturalistic revolution in the theatre was over, and there was knocking at the gates a new generation of playwrights, poets, and romantics with a longing for beauty, color, and music; also a new generation of playgoers, who were bored by Brahm's drab naturalism. Thus, it became the mission of Max Reinhardt to restore to the theatre its forgotten glamor and magic. Brahm had started out as a scholar, but Reinhardt came from Austria and had in his blood all the elements of the baroque theatre. He created

*MAX REINHARDT*

CULVER SERVICE

an impressionistic style of colorful brilliance. His task was greatly facilitated by certain discoveries which the Swiss designer, Adolphe Appia, had made in Bayreuth, where he became disappointed by the representational, realistic production style which Richard Wagner had adopted. But while Reinhardt never subscribed to Appia's theory of an abstract plastic setting, he shared Appia's belief in the expressive potentialities of light. Another symbolist designer and director, Gordon Craig, likewise revolted against the naturalistic theatre and tried, more successfully in theory than in practice, to translate the spiritual demands of poetic drama into scenic values. Craig, too, had the highest regard for light as the greatest painter of scenes. But while Craig showed little interest in the actor, in Reinhardt's theatre the actor always reigned supreme. Reinhardt directed in circus arenas and market squares, in churches and imperial ballrooms; he made theatre for thousands and for the few invited guests of a dinner party. But he treated his spectators always as participants in a festival. Brahm had been a literary director; Reinhardt often ran into the danger of overemphasizing the scenic elements at the expense of the literary values.

**Expressionism and Constructivism.** After World War I, Reinhardt had the feeling that Berlin no longer understood him. New directors with new styles were taking the capital by storm. One of them was Leopold Jessner, who had taken over the Prussian State Theatre in 1919. Jessner did away with illusionistic scenery, on which Reinhardt had relied. He rediscovered the stage space and found new possibilities for the physical play of the actor's body and the arrangement of groups. In almost all of his productions stairs were very much in evidence, the so-called *Jessner-Treppen* style, which in combination with neutral practicable platforms served as foundation for the burning dynamic intensity of Jessner's actors. Jessner was the chief exponent of the expressionistic style of production. Despite the temptation of a politically aroused time, Jessner never succumbed to the lure of political agitation. Erwin Piscator's theatre on the other hand, had its very starting point in the conscious propagation of the class-struggle theme. Like Jessner's, Piscator's stage was a functional acting platform. As a rule, Piscator's scenery consisted of a skeleton frame in the style of Russian constructivism. He used mechanical devices (motion pictures, globe segments, the treadmill) excessively, although he was serious hampered by the technical inadequancy of his Nollendorfplatz Theater. Walter Gropius' designs for an ideal Piscator theatre (*Totaltheater*) remained in the blueprint stage.

**American Stars, Manager, and National Schemes.** The American theatre of the nineteenth century was ruled by the star system. The first English stars to appear in America were representatives of the romantic school of acting, such as George F. Cooke, Edmund Kean, and Junius Brutus Booth. Next came William Charles Macready, who added domestic touches and realistic by-play to the romantic background. The Macready fever coincided with the emergence of the Philadelphian, Edwin Forrest, the successful rival of Macready. Soon after, other native stars were able to hold their own against the transatlantic guests—the great tragic actress Charlotte Cushman, Joseph Jefferson III (*Rip van Winkle*), and Edwin Booth, America's greatest actor, who had a position similar to that of Henry Irving in England. New managers arose, who built new theatres and had new ideas about stage direction. In this group belong James William Wallack and Lester Wallack, Laura Keene (the American Madame Vestris), Edwin Booth, Augustin Daly, and the great pioneer Steele MacKaye. No other American manager and stage director, however, commanded greater attention than the showman David Belasco, whose stage and, above all, lighting effects became the talk of the town after 1902, when he opened the remodeled Republic Theatre in New York. The wish to have a theatre of his own was chiefly prompted by the fact that in 1896 a group of sixteen theatre men had formed what became known as the Theatrical Syndicate. This trust controlled the leading theatres all over the country and dictated their terms to the producers, playwrights, and actors. In 1911, the syndicate was finally broken and Belasco must be given credit for this outcome of the struggle against monopoly. Belasco's photographic realism had lost its appeal by the end of World War I, when Arthur Hopkins and Robert Edmond Jones joined forces for a theatre of imagination against Belasco's illusionistic tricks. The greatest impetus which the American postwar theatre received came from experimental co-operatives, such as the Provincetown Players, the Washington Square Players, the Theatre Guild, and the Group Theater. In order to help unemployed artists, the Federal Government, under the Works Progress Administration, asked Congress to subsidize, among the other arts, the theatre. The Federal Theater Project (1935-1939) had potentialities of becoming the basis of a national theatre, but was not given the time to develop from a sociological into an artistic institution. In 1935, a group of drama-minded citizens obtained from Congress a charter for the founding of The American National Theatre and Academy (ANTA) which, having been rather dormant for several years, after World War II sponsored performances of new plays in its Experimental Theatre. The community and university theatres of America are represented in the National Theater Conference, an organization which functions as a stimulus for theatrical amateur activities throughout the nation. *See also* COSTUMES; PLAYHOUSES; STAGE.

**THEATRICAL AND FESTIVE MASKS,** two of the best known types of masks worn by man. Varying in size from great headpieces to tiny dominos, or half masks, they have been used in dramatic presentations and on festive occasions for centuries.

**Theatrical Masks.** *Greece.* The theatrical mask was used by the Greeks as an essential part of their theatrical entertainments. Just as they were the first to have a theatre for public performances, so were the Greeks the first to use the mask as an important adjunct to a completely theatrical

presentation. The more-than-life-sized masks they used completely covered the head, and had front and side hair attached. They were made of painted canvas with openings for the eyes and the mouth.

The Greek theatrical mask served a three-fold purpose. Since only three male speaking actors were permitted on the Greek stage, the use of a mask permitted each one of the three to double or triple the number of roles he could assume in one play. It enabled him to play female parts, to appear in various stages of manhood, and to sustain and intensify extreme characterizations when the role demanded them. The second function was to help the spectators to recognize characters more easily, for the open theatre was vast, even larger than some of our modern stadiums, and the spectators, of which there were often tens of thousands, were necessarily far removed from the stage. A definitely characterized and familiar mask, such as one of tragedy or comedy, helped to identify the character, even when seen from a great distance. A third purpose of the mask was to amplify the voice; the mouth was equipped with a brass device similar to a trumpet which projected the words spoken by the actor to the farthest reaches of the theatre.

Some use of the theatrical mask was made by the Romans, but with the growth of Christianity it was labeled pagan and fell into disuse.

*Japanese Nô masks made by Iwao Kongow.* (Left) *Male;* (Right) *Female.*

*Japan.* The theatrical mask has been used in Japan since the seventh or eighth centuries. Its use in *Bu-gaku,* or court masked dances, is said to have been introduced from China. These functions, performed by nobles in palaces and temples, called for the use of large and elaborate masks. They were the forerunner of the *Nô* plays, a form of drama which came into being about the fourteenth century and is in existence, unchanged, today.

The *Nô* plays, of which 210 are still in existence, are short, lyrical tales based on Japanese religious folklore, with which practically all Japanese are familiar. At first presented only by nobles, as were the court dances, for members of their own class, they eventually became a cherished national pastime. Only males are allowed to appear in them and the actors' costumes are carefully prescribed, as are the masks worn by the principals. Because of this, the audiences instantly recognize the characters as they appear. About 120 named varieties of masks are used in the *Nô* dramas and are classified in five types: old person, male, female, god or goddess, and devil or goblin. These masks cover only the face but head-dresses are generally worn with them. They are made of wood which is carved, given a coating of plaster, and then lacquered. Some specimens, still in use, are of great antiquity and are highly valued for their sculptural qualities. The subtlety and refinement of the modeling in the *Nô* masks, and their infinite variety, demonstrate the great ability of the Japanese artists to observe and reproduce the wide range of human facial expression as it typifies the traditional characters of their folklore. It is said of the masks, in fact, that they appear to change in expression when seen in movement on the stage.

*Modern.* Theatrical masks are seldom seen in contemporary dramatic productions. From time to time they have appeared, as they did in the nineteen-twenties, when the talented maker of masks, W. T. Benda, succeeded in reviving them for use in drama, dance, and pantomime. The followers of E. Gordon Craig, the stage designer, have shared his enthusiasm for masks, and they were part of such productions as *Oedipus Rex* and *The Great God Brown,* where they were used to suggest the alter ego of an individual. On the whole, however, the appearance of the mask as an adjunct to present-day theatrical presentations is so isolated that it must be concluded that it is no longer vitally needed in the theatre.

**Festive Masks.** The festive mask, made for traditional holidays, is the most widely used descendant of the ceremonial and theatrical masks. Its history, too, is long. In Siam, Java, and Burma, and all through the Orient, the religious mask gradually lost its early meaning and frequently appeared only as an elaborate piece of decoration. Although morality and miracle plays made some use of religious masks in medieval Europe, a more conspicuous use of them was made in such seasonal festivals as the "Feast of Fools" and "The Boy Bishop," which were dominated by an almost pagan spirit of revelry. These and similar festivals were eventually banned by the Church in the fifteenth century.

The Commedia dell'arte flourished in Italy from the fourteenth century to the seventeenth and produced the still-famous masked characters of Harlequin, Pulcinella, and other classic figures. While the mask was a featured part of these improvised plays, its dramatic use was superficial in nature. However, the domino half-mask and the masquerade balls, which are still part of our festive occasions, are derived from this source.

The comedy theatres of France adopted the manners of the Commedia dell'arte and used the mask in many of their sophisticated comedies and their pantomimes. Pierrot and Pierrette became the counterparts of Harlequin and Pulcinella; their vogue, and also that of the mask and masquerade, persisted in France, as it did in Italy, throughout the eighteenth century. Its penetration into social modes and manners was marked by the liberties in human behavior

*SWISS CARNIVAL MASK*

COURTESY OF THE BROOKLYN MUSEUM

during traditional holidays that have long been indulged in by wearers of masks.

Swiss carnival masks, used in connection with certain of their festive seasons, are lively and humorous. Deft characterizations and an ingenious and interesting use of materials make these masks among the most expressive in contemporary use.

Another present-day use of the festive mask is seen each year in New Orleans during the Mardi Gras celebration, which reaches its climax on Shrove Tuesday, the day before Ash Wednesday, the beginning of Lent. The origin of this Shrove Tuesday festivity is somewhat obscure, but masked parades have for a long time been one of its most important features.

On the whole, the children of today are the most ardent wearers of the festive mask. Christmas, Thanksgiving, Hallowe'en, animal, and character masks are a regular part of their little celebrations. Wearing these masks, the children, even as their primitive ancestors, lose their identities and take on those represented by the masks they wear. *See also* RELIGIOUS MASKS. O. L. R.

**THEBAID, THE** [thi'beid], an epic poem by Publius Papinius Statius, in ten thousand hexameters and twelve books. Derived from the popular Greek story, the *Thebaid* describes the rivalry of the brothers Polyneices and Eteocles for the throne of Thebes. Exiled by his brother, Polyneices enlists allies at Argos, but Thebes is successfully defended from his attack and all of Polyneices' allies are killed. In fulfillment of the curse of their father Oedipus, Polyneices and Eteocles then proceed to kill each other in single combat. Creon assumes the throne and prohibits the burial of Polyneices and other invaders. Jocasta, Oedipus' mother and wife, stabs herself, and Oedipus is dissuaded from suicide and saved from exile only by the intercession of his daughter Antigone. G. McL. H.

**THEBES** [thi'bz], the best-known archaeological site in the Upper Nile Valley, is situated on the banks of the Nile River about 300 mi. south of Cairo. The name Thebes, first known from the *Iliad,* was given the city by the Greeks, possibly because, like Greek Thebes, the city was renowned for its gates. Its Egyptian name was Waset. The site of a part of ancient Thebes is occupied today by Luxor, with 24,118 inhabitants, and Karnak, with 10,865, both on the east bank of the Nile, but ancient Thebes also included a large area on the low land of the west bank, extending up into the foothills, which was mostly devoted to tombs and funerary temples.

During the Old Kingdom (c. 2850-c. 2052 B.C.), Thebes was an inconspicuous provincial capital, ruled by semi-independent princelings who are represented now only by a few rock-cut graves. After an interim of disturbances, their successors began a struggle for the unification of Egypt and finally brought the country under the House of Thebes in the Middle Kingdom (c. 2052-c.1778 B.C.), which marked the beginning of Theban prosperity. Although the great temple-building activity of the New Kingdom has obscured most of the original buildings of this period on the east bank, on the west bank the tombs of some of the rulers, notably that of Mentuhotep II of the Eleventh Dynasty (c. 2052-c.1991 B.C.) at Deir el-Bahri, are still to be seen. During part of the Middle Kingdom, the capital was shifted north to Memphis for administrative reasons, but the kings were still of Theban origin. Toward the end of the Middle Kingdom, when internal strife impaired the unity of the country, the kings of the Thirteenth Dynasty re-established their residence at Thebes. Some modest rock-cut tombs were laid out for them, and inscriptions record their donations to the temple of Amen at Karnak.

Thebes stagnated during the foreign rule of the Hyksos (c. 1670-c. 1570 B.C.), a people of disputed origin from Western Asia, but it was from Thebes that the war to drive out the Hyksos was successfully undertaken. Ahmosis, the first king of the Eighteenth Dynasty (c. 1570-c. 1345 B.C.) finally defeated the invaders, but it was his older brother, Kamose, the last king of the Seventeenth Dynasty, who laid the foundations for this defeat by consolidating Upper Egypt. The royal cemetery of the Seventeenth Dynasty had already been plundered in ancient times, yet some of the splendid funerary equipment has survived; elaborately wrought weapons decorated with inlay work were especially common in tombs of this period.

With the Eighteenth Dynasty, the New Kingdom (c. 1610-715 B.C.) begins, a period of tremendous prosperity for Thebes and its chief god Amen and the Golden Age of Egypt as well as Thebes. It remained for many centuries the chosen residence of the pharaohs and the treasure house for the rich tribute garnered from conquered lands. The wealth of Amen doubled and redoubled, and the power and influence of his priests, who numbered some of the foremost men of Egypt, grew with their wealth.

The great temple structures which rise on the east bank of the Nile are, outside of the pyramids, the most imposing remains in Egypt today. The temple of Amen at Luxor, like its greater counterpart at Karnak, was not built at any one time, as is evident from its plan, which includes a complex and reduplicated series of pylons, colonnaded forecourts, and hypostyle halls. This temple was begun by Amenhotep III (c. 1413-c. 1377 B.C.) on the site of an earlier sanctuary and was considerably altered and enlarged in later years, particularly by Rameses II (c. 1301-c. 1234 B.C.), the greatest builder of all the pharaohs, who added a large new colonnaded court and flanked the entrance with enormous pylons, in front of which stood colossal statues of himself. One of the better-preserved statues is approximately 55 ft. high, which gives an indication of the vast scale of the temple. In Christian times, part of the temple was used as a church, and at present a tiny mosque still stands in its northern section.

At Karnak, the temples to Mut, Amen's spouse, his son Khons, and the war god Mont, impressive as they are, are dwarfed by the Great Temple of Amen which, as it stands today, is over a fifth of a mile long. The core of the temple goes back at least as far as the Twelfth Dynasty of the Middle Kingdom, and beginning with Thutmose I, early in the New Kingdom, it was constantly remodelled and enlarged by the addition of a succession of courts, colonnaded halls, and pylon after pylon. Of the individual parts of the temple, the great hypostyle hall of Rameses II is perhaps most notable; its size is such that the entire cathedral of Notre Dame could be placed within it. These temples are all embellished, both without and within, with reliefs and inscriptions, most of them relating to the accomplishments of the various pharaohs.

The tombs of these pharaohs, with few exceptions, were placed in the "Valley of the Kings," a spot more difficult of access than the earlier cemeteries which had been so consistently plundered. Since the valley did not offer enough space for the increasingly grandiose funerary temples, a line of majestic mortuary structures began to rise along the west bank. An exception is the great terrace-temple of

EWING GALLOWAY

*REMAINS OF THE NORTHERN PART OF THE HYPOSTYLE HALL OF THE RAMESSEUM AT QURNA IN ANCIENT THEBES*

Queen Hatshepsut (c. 1501-c.1480 B.C.) at Deir el-Bahri, next to that of Hatshepsut's Middle Kingdom predecessor Mentuhotep.

The court of Amenhotep III (c. 1413-c. 1377 B.C.) in the latter part of the Eighteenth Dynasty surpassed in luxury anything previously seen in Egypt; his funerary temple is still marked by two of the colossi which fronted it—the "Colossi of Memnon" so much admired by Roman travelers, many of whom inscribed the record of their visits on the statues themselves. Of other funerary temples along the west bank, the best-known is the so-called Ramesseum of Rameses II.

Under Amenhotep IV (Ikhnaton), the capital was temporarily removed to Amarna. It was returned to Thebes by his son-in-law Tutankhamen, the discovery (in 1922) of whose unrifled tomb in the Valley of the Kings stirred the world. All the funerary equipment of Tutankhamen's tomb is preserved, including the king's mummy in its golden coffin, and its wealth suggests the magnificence of the lost offerings from the larger and more important royal tombs near by.

With the rise of the Twenty-Sixth Dynasty (Saïte period, 663-525 B.C.), the political center of Egypt again shifted north, and the ancient capital lost its political significance; but it remained an important religious center, and after the conquest of Egypt by Alexander the Great it momentarily recovered its independence. The earlier Ptolemies continued to increase the size and beauty of the temples and even to build anew, but the last Theban revolt ended in the destruction of Thebes as a city about 30 B.C. Strabo (24 B.C.) found there only scattered villages, but until late Imperial times the magnificent ruins attracted numbers of sightseers, as indeed they do today, while with the rise of Christianity the temples and tombs became churches and monasteries devoted to the worship of the new God. *See also* EGYPTIAN ARCHITECTURE, ANCIENT; KARNAK, TEMPLES OF; LUXOR.

J. H. Y.

**THEBES** (Gr. Thívai), a city in Boeotia, in central Greece. The town of Thebes lies in well-watered and fertile rolling country which has been inhabited since prehistoric times. Thebes was reportedly founded by the legendary Cadmus, a Phoenician who introduced the alphabet to the Greeks. The story may preserve a rememberance of the writing of Mycenaean times, for Thebes was the principal Mycenaean city in Central Greece. She does not appear in the Catalogue of Ships in the *Iliad,* having been destroyed by the Argives, according to tradition, but in the sagas of the Heroic Age the Theban cycle was second only to the Homeric.

In Classical times, Thebes was the foremost city of Boeotia, normally dominating the loosely organized Boeotian League. She was one of the "Medizing" Greek states in the Persian Wars and temporarily lost this dominance as a result. During most of the fifth century she was engaged in intermittent wars of rivalry with Athens, but after the decline of Athenian power at the end of the Peloponnesian War she occasionally allied herself with Athens against the Spartans. For a brief period in the early fourth century, Thebes, at the head of the Boeotian League, was the chief city-state in Greece. With Epaminondas as her leader, she was at the height of her power when she defeated the Spartans at the Battle of Leuctra in 371 B.C. Epaminondas was killed at the Battle of Mantinea in 362, and thereafter Theban power quickly declined.

Philip of Macedon was educated at Thebes, and this training stood him in good stead in his aggression against the Greek city-states. Thebes, together with Athens, was disastrously defeated by Philip at the Battle of Chaeronea in 338 B.C., and her famous "Sacred Band" was annihilated. Her revolt against Alexander in 335 caused him to raze the city, sparing only the temples and the house of the much earlier Theban poet, Pindar. Although rebuilt by Cassander not long afterward, Thebes never again regained her importance in antiquity.

Parts of ancient Thebes have been excavated, particularly the temple of Ismenian Apollo and areas of the Mycenaean city and palace.

During the Middle Ages, Thebes was an important center for silk-making and dyeing and was the capital of the

Frankish Duchy of Athens. Under Turkish occupation, she again sank into an obscurity from which she did not emerge until modern times. Pop. 1951, 12,582. *See also* CADMUS; EPAMINONDAS; SEVEN AGAINST THEBES, THE. J. H. Y.

**THECLA OF ICONIUM, ST.** [thē'klə] (first century), Christian saint, "protomartyr among women and equal to the Apostles," is known from the apocryphal *Acts of Paul and Thecla.* Converted by St. Paul, she dedicated herself to virginity. Condemned to death for her faith, she was miraculously preserved and retired to Seleucia. Her feast is September 23. W. C.

**THE DALLES** [thə dæ'lz], a city in northern Oregon, the county seat of Wasco Co., 70 mi. east of Portland, situated on the south bank of the Columbia River, at the mouth of Mill Creek. The completion of the Bonneville Dam and the locks make the city a Pacific Coast port with a 200-mi. waterway to the ocean. Pine timber is abundant in the region, and 11 mi. eastward up the Columbia are Celilo Falls where the Indians fish during the salmon run. The Dalles is the trading center for an agricultural area. Lewis and Clark visited the site in 1805. The first white settlement in 1838 was abandoned after the Whitman Mission massacre in 1847. Fort Lee was built in 1849, and a town grew around it. Fort Dalles received its city charter in 1854 and shortly changed the name to Dalles City, but the Post Office Department called it The Dalles, which was adopted by the city. The city is governed by a council and manager. Points of interest include the Federal Building, the county courthouse, the parade ground of old Fort Dalles, and a mint which was erected in 1868 by the Federal Government but never used to coin money. The Union Pacific Railroad and the United Air Lines serve the city. Industrial establishments comprise railroad shops, flour and lumber mills, and salmon fisheries. Pop. 1950, 7,676.

**THE HAGUE.** *See* HAGUE, THE.

**THEISM,** belief in God; specifically, belief in one eternal, personal God, who is both immanent and transcendent. God's immanence means that he is in the world of persons and things as their creative ground and sustainer. His transcendence means that his personality and purposes include more than is evident in the world. Theism is contrasted with polytheism, which is the belief in many gods; with deism, which excludes God's immanence; and with pantheism, which excludes God's transcendence. Theism is the opposite of atheism. The term theism is frequently used as a synonym for natural theology, in contrast with revealed theology.

**History.** The word theism was used as early as 1678. Originally synonymous with deism, it has come to have its distinctive meaning since the close of the eighteenth century. Monotheistic belief arises in the development of most of the higher religions, often following a polytheistic stage. This rise may be observed in religions of China, India, Egypt, Greece, and Rome, as well as in the Judaeo-Christian religion. The theistic God is not only an object of religious worship, but also, in some systems of philosophy, a principle of philosophical thought. The number of such systems includes those of Plato, Aristotle, Ramanuja, St. Thomas Aquinas, Locke, Berkeley, Descartes, Kant (a modified theist), Lotze, modern neoscholastics, personalists, and religious realists. H. N. Wieman and certain other philosophers of the second quarter of the twentieth century who reject the personality of God speak of themselves as naturalistic theists.

**Theistic Arguments.** Many arguments intended to prove the existence of God have been advanced in the course of history, eight of them sufficiently well known to warrant special mention. (1) The cosmological argument holds that the world as dependent and conditioned requires an independent and unconditioned first cause. (2) The teleological argument holds that the signs of adaptation and purpose in the world require God as an original purposer. (3) The ontological argument holds that the very idea of God as a perfect being implies his existence, either because perfection includes and requires existence (Anselm's view), or because an idea of perfection requires a perfect cause (Descartes' view). St. Thomas did not accept the ontological argument, and Kant subjected the cosmological and teleological arguments to searching criticism. (4) Kant's moral argument holds that moral law presupposes God as ground of the moral order. This moral argument and the four which follow have been specially emphasized in post-Kantian times. (5) The axiological argument holds that the total experience of value—logical, moral, aesthetic, and religious—points to God as a personal source of value. (6) The argument from interaction holds that the causal interaction of things presupposes a unitary and personal ground of interaction. (7) The idealistic or personalistic argument holds that conscious personality is inexplicable as a result of unconscious forces, and requires a cosmic person as its explanation. (8) The argument from religious experience holds that religious (particularly mystical) experience is a direct awareness of God or of co-operation with him.

**Theistic Belief in the Twentieth Century.** The development of science, the evolutionary theory, naturalistic philosophies, and positivism, combined with increasing secularism and the pessimism aroused by World Wars I and II, have produced a climate of opinion unfavorable to theistic belief. Prominent thinkers like Bertrand Russell, John Dewey, and George Santayana have rejected traditional theism. Positivism, with its rejection of all propositions that cannot be expressed in a physicalistic language and verified by the senses, is hostile to theistic belief. But no essentially new antitheistic arguments have arisen; and many physical and biological scientists, as well as a number of eminent philosophers, including A. N. Whitehead, W. E. Hocking, James Ward, B. P. Bowne, and J. E. Boodin, have found some form of theism acceptable. *See also* ANTHROPOMORPHISM; ATHEISM; DEISM; PANTHEISM; POLYTHEISM.

E. S. B.

**THEME,** in music, a sequence of tones that serves as the basic idea or subject of all or part of a musical composition, filling the same function as the text of a sermon or the subject of a debate. Broadly speaking, the theme belongs to purely instrumental music, the melody to vocal music. The differences between the two, which are not always distinct, therefore arise from the differences between their respective media: a melody tends to be a well-rounded, self-contained unity so bound by the limitations of the human voice as to be "singable"; a theme is often short, lacking a clear-cut physiognomy, entailing leaps and rapid progressions playable only on an instrument, and existing more as a potentiality for development than as an entity. More specifically, the theme includes the brief figure or motive that abounds in Baroque music, the well-defined subject of the fugue, and the underlying ideas in sonata form.

Between 1600 and 1900, themes became increasingly tangible and more melodic in shape and character, and their significance in musical form increased proportionately. The Classical theme is sometimes only a germinal idea as in the

"fate" motive of Beethoven's Fifth Symphony, but it ordinarily differs from the Baroque motive in both its completeness and its contrasts within itself. During the Romantic period there was wide variation in theme, from the brusque, angular themes of Richard Strauss to the leisurely, song-like melodies of Schubert, but many modern composers have reverted to the motival theme of the Baroque era. W. S. N.

**THEMIS** [thi′mɪs], in Greek mythology, the personification of justice, who presided over the assemblies of gods and men. She was a Titaness, the daughter of Uranus and Gaea, and was beloved by Zeus, to whom she bore the Hours and the Fates. *See also* TITANS. G. E. D.

**THEMISTOCLES** [thəmɪ′stokliz] (c. 514-c. 450 B.C.), Athenian statesman. The son of an Athenian father and a foreign mother, Themistocles attained political leadership at Athens through talent alone. His influence was always resented by the Athenian aristocrats, who had reigned supreme in the councils of Athens before his time. If it had not been for the crisis precipitated by the Persian invasions, birth instead of worth might have continued to be the criterion for high office at Athens.

**Triumph over Aristides.** The fundamental policy of Themistocles was based on his theory that Athens must become a sea instead of a land power. It is believed that as early as 493 B.C., when he held his first archonship, he began the building of a naval base at Piraeus. Then, in the decade following the Battle of Marathon in 490 B.C., Themistocles carried on his campaign for a big navy, against the conservative followers of Aristides, who favored a large army. The question was finally decided in 483 B.C. when Aristides was ostracized. In the following year, Themistocles was able to persuade the Athenians that they should use the new revenues from the silver mines at Laurium to build a fleet of two hundred triremes to meet the inevitable invasion which Xerxes was preparing.

**Victory over Persians.** When the Persian invasion began in 480 B.C., it was Themistocles who forced the Greeks to make a stand at Salamis and fight it out with the Persian fleet there instead of withdrawing to the Peloponnesos, as the Spartans and many others wished to do. As the Greeks wavered and considered fleeing from Salamis before they could be trapped by the Persian fleet, Themistocles sent a message to Xerxes that the Greeks were planning to flee and that the Persians would do well to attack immediately. As a result, the Persians were drawn into a narrow, unfavorable strait where the lighter, swifter Greek ships could outmaneuver them. This was the essential strategy of the great victory at Salamis in 480 B.C.

**Decline and Exile.** When Athens was reoccupied and the Athenians wished to rebuild their walls, they were opposed by the Spartans, who wanted to keep Athens an open, undefended city. Themistocles then went to Sparta and kept the Spartans occupied with negotiations while the Athenians rebuilt their walls. When the Spartans sent envoys to Athens to discover what the Athenians were doing, they were held as hostages for the safe return of Themistocles. Themistocles was probably responsible for the creation of the Delian League, which placed Athens at the head of a large naval force and helped to counterbalance the land strength of Sparta and the Peloponnesian League. After the formation of the Delian League in 477 B.C., political influence at Athens passed to the great military and conservative leader, Cimon, and the power of Themistocles waned. He was ostracised in 471 and soon thereafter was involved in the scandal which brought the downfall of the Spartan general Pausanias. Hunted as a traitor who had held treasonable correspondence with the Persians, Themistocles at last fled to Persia about 464 and was well received by Artaxerxes, who had just come

*THEMISTOCLES*

CULVER SERVICE

to the Persian throne. Themistocles died in Asia Minor, perhaps as a suicide, about 450 B.C. T. B. J.

**THEOBALD** or **TEDBALDUS** [thi′obɔld, tɪ′bəld; tɛdbɔ′ldəs] (d. 1161), archbishop of Canterbury, was of Norman descent. He became a Benedictine monk of the abbey of Bec sometime between 1093 and 1124, was made prior in 1127, and abbot in 1137. In 1138 he was elected archbishop of Canterbury and consecrated the following year. In the long struggle between King Stephen and the Empress Matilda, Theobald loyally adhered to the King, whom he crowned, though his sympathies lay with the Angevin Party. He was for several years involved in difficulties as a result of the appointment of the Bishop of Winchester as papal legate, causing a division of authority in the Church of England. Although the latter's commission expired with the death of Innocent II in 1143, Theobald did not receive legatine authority until 1150. Despite Stephen's interdict, he attended the council of bishops summoned by Eugenius III at Reims in 1148, and there saved the King from excommunication. In 1152, acting on papal authority, he refused to crown Eustace, the King's son, and as a consequence was forced into exile, but was recalled by Stephen at the end of the year. When Henry of Anjou was in England in 1153, Theobald reconciled him to the King, making possible the treaty of Wallingford (1153), which ended the civil war. On Stephen's death the following year, he crowned Henry II. Theobald attached to his household many young men of outstanding talent, chief among whom were Roger de Pont l'Evêque, Thomas à Becket, and John of Salisbury. He was also the first to introduce the study of civil law into England, and founded a law school at Canterbury, where the famous Italian jurist Vacarius lectured on Roman law. Theobald died on Apr. 18, 1161. C. W. D.

**THEOBALD, LEWIS** [thi′obɔld; tɪ′bəld] (1688-1744), English dramatist, translator, and editor, was born in the early part of April 1688 at Sittingbourne, Kent. He early made translations from the works of Classical writers: Plato (1713), Sophocles (1714-1715), *The Odyssey* (1716), and Aeschylus (unpublished). He also wrote for the stage, bring-

ing out tragedies, including an adaptation of Shakespeare's *Richard II* (1719), and many pantomimic and operatic pieces. His major work, however, was his editing of Shakespeare. In 1726 he published *Shakespeare Restored,* a criticism and correction of Alexander Pope's edition of Shakespeare (1725), and in 1734 printed his own edition of Shakespeare in seven volumes, a work which went through three editions between 1734 and 1757. Theobald's importance as an editor of Shakespeare lay in his good sense, his application of the spirit and method of modern scholarship to Shakespearean problems, and his elevation of English literature to more serious study by giving it the careful, scholarly attention which had previously been accorded Classical authors. Theobald died in London, Sept. 18, 1744. E. L. A.

**THEOCRACY** [thiɒ'krəsi], literally "rule by God," a term applied to any state the government of which is devoted primarily to the achievement of religious ends or is markedly subject to an organized priesthood. The term includes forms in which a supernatural being is conceived directly to exercise sovereign power, as well as those in which divine power is wielded through human intermediaries. Common among Oriental monarchies, theocratic characteristics were displayed in the Papal States, in Calvinist Geneva, and in America in Puritan Massachusetts, Mormon Utah, and Paraguay. F. V. C.

**THEOCRITUS** [thiɒ'krɪtəs] (fl. third century B.C.), Greek bucolic poet, a younger contemporary of Callimachus, was born at Syracuse near the end of the fourth century B.C. We learn from an epigram that his parents were Praxagoras and Philina. Early in his career he lived in Cos, an island

*THEOCRITUS*

CULVER SERVICE

with which his mother's family may have had some connection. In Cos he met the poets Philetas and Asclepiades, among others, and probably began a lifelong friendship with the doctor-poet Nicias. Returning to Sicily about 280 B.C., he sought unsuccessfully the patronage of Hiero, tyrant of Syracuse. Ptolemy Philadelphus of Egypt proved more receptive, and from 274 to 270 Theocritus enjoyed the hospitality of Alexandria. He apparently returned to Cos for some years and may have visited Miletus, the home of Nicias. His best period must have been 275-260 B.C., and he must have reached a reasonably old age, since he speaks of gray hairs in Idyll xxx and Statius refers to him as *"Siculus senex"* ("the elderly Sicilian"). This scanty account is largely derived from Theocritus' own writings, since there is little evidence that even the ancients knew much about the poet's life. The surviving body of works traditionally ascribed to Theocritus consists of thirty idylls (short poems) and more than twenty epigrams. The authenticity of the epigrams is difficult to estimate though many are worthy of Theocritus; of the idylls only twenty-two can fairly be regarded as genuine. The catalogue of lost works, which includes hymns, heroines, dirges, elegies, and iambics, bears testimony to the poet's versatility.

Theocritus is generally regarded as primarily a poet of pastoral life, but only one-third of the preserved collection of his idylls consists of pastoral poems. Such poems are, in fact, only part of a larger category of dramatic pictures of both country and city life, sometimes in monologue form, sometimes in dialogue. A regular feature of the dramatic poems is the inserted song, whether assigned to one or to alternating voices. Such songs may be found in the *Thyrsis, Serenade, Herdsmen, Goatherd's Song, Harvest Home,* and *Reapers,* all poems of country life; they enter into city scenes in the *Spellbinders* and the *Syracusan Women.*

Independent lyrics and poems of a similar character form a second group of idylls. Two love poems, Aeolic in dialect and meter, owe their inspiration to the lyric tradition of Lesbos; a third Aeolic poem was sent with Theocritus' gift of a distaff to the wife of Nicias. Another love poem, *The Beloved,* is written in the Ionian dialect instead of Theocritus' usual Doric. Two court poems, the *Graces,* addressed to Hiero, and the *Panegyric of Ptolemy* add little to the writer's reputation.

The third group of idylls is composed of short poems treating epic subjects in various fashions. The *Cyclops* and *Hylas* are addressed to Nicias; both consist of mythological love stories within a letter-like framework. The former tells how Polyphemus soothed his love pangs by singing to his beloved Galatea; the second suggests that even the strongest of men, Heracles, could be overcome by love. The *Wedding Song of Helen* may have been inspired partly by Stesichorus, partly by Sappho's *Wedding Songs;* the *Hymn to the Dioscuri,* a typically Alexandrian modification of an old form, is half dramatic, half narrative; the *Infant Heracles* is notable for its picture of domesticity; and *Heracles the Lion-slayer* seems to be an incomplete sketch made up of three unrelated episodes.

Theocritus' pastoral poems, rooted in the Sicilian songs he knew so well, have a freshness and vigor—in spite of their artificial form—which all his successors lack; the vividness of such dramatic scenes as *Syracusan Women at Adonis' Festival* owes much to the Sicilian tradition of dramatic representation of humble life established by Epicharmus and Sophron. The example of Stesichorus may have aided Theocritus in his Hellenistic modifications of epic themes. The frigid hand of Alexandria hardly touched him except in his *Panegyric of Ptolemy.* At his best he offers a unique combination of the nature lover and the artist, of realism and convention; at his worst his sympathetic humor and sense of aesthetic propriety give him gracefulness.

The bucolic tradition which Theocritus established owes much to his influence, direct or indirect. Moschus and Bion followed him in Greek; in Latin Vergil's indebtedness is apparent, and Vergil passed on the tradition to Calpurnius and Nemesianus. In the sixteenth century, through original text, translation, and adaptation, Theocritus' influence began to spread over western Europe and England, and has persisted to influence American writers as well. C. M. D.

**THEODORA** (c. 508-548), wife of the Roman Emperor Justinian. Most of the information now available about Theodora comes from a hostile source, the historian Procopius. Theodora, whose father is said to have been a bear-keeper at the Hippodrome, first rose to fame as an actress who had more personality than talent. Like many other

professional entertainers of antiquity, Theodora was a courtesan. In this capacity she attracted the attention of Justinian. They were married about A.D. 523, and when Justinian became emperor in 527 Theodora sat beside him on the throne as empress. In this exalted position she strove for respectability. She took a great interest in charities and established an institution for fallen women; she also extolled the virtues of marriage and arranged a number of matrimonial alliances at the court. In the field of imperial affairs, Theodora exercised great influence over Justinian. She is supposed to have determined his policies even to the point of giving orders to his generals. The suppression of the Nika riots of A.D. 532 was the direct result of Theodora's courage and steadfastness at a time when Justinian himself might have jeopardized his throne through lack of a firm policy. Naturally the influence of Theodora was resented by various factions at the court. Her love of Oriental ostentation, as well as her support of the Monophysite sect, offended many people, but her domineering personality alone would have been sufficient to arouse considerable hostility. T. B. J.

**THEODORE** (Rus. Fyodor or Feodor), the name of three tsars of Russia.

**Theodore I** (1557-1598). The son of Ivan IV, the Terrible, and Anastasia Romanovna, Theodore I succeeded his father in 1584. As he was physically and mentally unstable, the real power of government was vested in his brother-in-law, the boyar Boris Godunov, who succeeded to the throne on Theodore's death in 1598. Theodore was the last of the Rurik Dynasty.

**Theodore II** (1589-1605). The son of Boris Godunov, Theodore II was proclaimed tsar on the death of his father, Apr. 13, 1605. On July 10 of the same year he was murdered, as the result of a boyar conspiracy to nip the Godunov Dynasty in the bud.

**Theodore III** (1656-1682). The son of Tsar Alexis I and Maria Miloslavsky, Theodore III Alexeyevich succeeded to the throne at the age of 15 and, until he became of age, ruled under the regency of his elder sister Sophia. His relatives, the Miloslavskys, who clung to the ancient traditions of Russia, on Theodore's accession seized the opportunity to banish the boyar, Matviyeyev, who had attempted to introduce Western ideas. Though an invalid, Theodore was a vigorous monarch and, among other administrative and cultural reforms, abolished one of the worst abuses of the Russian nobility, the *miyestnichestvo,* a system of precedences and privileges among the boyars, according to elaborate and carefully preserved Books of Rank. He also founded an academy at Moscow at which Greek and Latin were taught, as well as Slavonic. On his death, on Apr. 27, 1682, he was succeeded by his brother Ivan V. C. W. D.

**THEODORIC THE GREAT** [thiɒ′dorɪk] (454-526), King of the Ostrogoths, was born in 454 in Pannonia, a Roman province in the region of modern Hungary and Yugoslavia. His father was the Ostrogothic King Theodemir. As a boy Theodoric spent ten years as a hostage at the Byzantine court at Constantinople. He gained his first military experience as a general when the Ostrogoths invaded Moesia and Macedonia in 473. As king of the Ostrogoths and a Byzantine vassal, Theodoric invaded Italy and attacked Odoacer in 488. After defeating Odoacer in 493, Theodoric ruled Italy for thirty-three years until his death in 526. The Italians remembered his reign as a period of peace and prosperity such as the peninsula had not known for over a century. The only unpleasantness occurred when Theodoric, an Aryan, permitted the execution of the Catholics, Symmachus and Boethius. T. B. J.

**THEODOSIUS I** [thi′odo′shiəs] (c. 346-395), called the Great, Roman emperor, was born in Spain about 346, the son of Theodosius, one of Emperor Valentinian's generals who was executed in 376. The younger Theodosius served with his father in Britain in 368 and in 374, and defeated the Sarmatians who had invaded Moesia. After the death of his father he lived in Spain, but was summoned to court by the youthful Emperor Gratian after the death of his colleague, Valens, at the Battle of Adrianople on Aug. 9, 378. Theodosius was invested on Jan. 19, 379, with the Empire of the East, comprised of Thrace, Asia, and Egypt. In 379 he defeated Gothic invaders, receiving their capitulation on Oct. 3, 382; he then made 40,000 of his former enemies *foederati,* and settled them along the borders of the empire. In 383 he had Arcadius, his eldest son, proclaimed Augustus. By the murders of Gratian and his successor, Maximus, Theodosius became in 388 sole head of the empire. In 389 he entered Rome, where he lived for the next three years. Having embraced Christianity and been baptized in 380, he decreed that all his subjects become Christians. He vigorously attacked superstition and idolatry, and promulgated numerous severe edicts against heretics. In 390 he ended a revolt in Thessalonica by a bloody massacre. Soon afterwards, Arbogast, Theodosius' agent in the West, revolted and advanced to the borders of northern Italy. His army under Eugenius almost destroyed Theodosius' troops, but on Sept. 6, 394, Theodosius was completely successful. He went to Rome, had his younger son Honorius proclaimed emperor of the West, and then retired to Milan, where he died on Jan. 17, 395. His empire was divided after his death between his sons, Honorius and Arcadius. Theodosius II (401-450) succeeded his father, Arcadius, in 408 as emperor of the East. The Theodosian Codex of imperial constitutions was completed in 438. He died in 450. T. R. H.

**THEOGNIS** [thiɒ′gnɪs] (sixth century B.C.), Greek elegiac poet, was born at Megara in Greece and probably resided in exile at Megara in Sicily. On the evidence of the political situation reflected in his poems, his chief productive period may be set between 550 and 545 B.C. Of the 1400 lines preserved under his name it is known that some were written by Tyrtaeus, Mimnermus, Solon, and Euenus. These probably constitute a group of independent collections of aristocratic precepts and songs, fairly representative of sixth- and fifth-century elegy. However, the passages addressed to a young friend, Cyrnus, are certainly by Theognis. Uncompromisingly bitter toward the commoners who expelled the aristocrats, and toward those nobles who betrayed their class by marrying into new but wealthy families, Theognis instructs Cyrnus in the behavior of the true aristocrat in politics and in society. The last 160 lines, forming a kind of appendix, consist largely of erotic verse. C. M. D.

**THEOGONY** [thiɒ′goni] (*Genealogy of the Gods*), a Greek didactic poem written by Hesiod (probably eighth century B.C.), which is an attempt to organize into a coherent system the legends concerning the origins of the world, the gods, and their descendants. From Chaos and Earth arose such deities as Night, Day, Heaven, Mountains, Sea, and Sky (Uranus)—that is, the various aspects of Nature—and others, including the Titans and Giants. Uranus remained preeminent until he was overthrown by his son, Cronus, who, with Rhea, established another dynasty. The descend-

ants of Cronus included, among others, Demeter, Hera, Hades, Poseidon, and Zeus. Cronus was replaced by Zeus, who by marriage with various goddesses created the third generation of gods. This account is followed by a list of the goddesses who married mortals and of their children. At some time later than Hesiod, perhaps, there was added the *Eoeae,* a catalogue of women who bore children to gods; apart from a number of scattered fragments, there is preserved only a transitional passage which was put at the end of Hesiod's poem to make the *Theogony* and *Eoeae* a continuous work. *See also* HESIOD. C. M. D.

**THEOLOGICAL EDUCATION,** or training for the religious ministry. This falls into four fields of study among Protestants: (1) theology, the rational explanation of the intellectual content of religion; (2) Biblical literature, including its concomitant study of Greek and Hebrew; (3) Church history, containing the historical and biographical details of the development of the Church and of the leaders in it from its beginning; and (4) practical theology, which includes the preparation and delivery of sermons, the organization and administration of the Church on both a local and national level, the art of ministering to the ill in the role of pastor, and other studies. The Roman Catholic Church makes a somewhat similar division of theological education, but under the following studies: ascetical theology, dogmatic theology, moral theology, mystical theology, natural theology, pastoral theology, and positive theology. In addition to theology, Biblical literature, Church history, and practical theology, studies in Jewish seminaries include such subjects as rabbinics, rabbinical literature, and Hebrew literature (medieval and modern).

The Roman Catholic Church divides its theological education into two parts. The preparatory seminary carries the candidate approximately to completion of Junior college. Then follows the major seminary education, two years being spent in the study of philosophy, and four in theology.

A. W. S.

**THEOLOGY** [thiɒ'loji], the systematic study of God and his relation to man. The word theology is derived from two Greek words, θεός, "God," and λόγος, which may be translated "science." Theology is thus properly defined as the science of God, but it is more adequately described as the science of God and his relation to man.

The word *theologian* was originally used to designate a man whose special task was to exalt the deity. In Greek literature Homer is described as a theologian because he wrote about the gods. Among the Romans the theologian was placed in the class of poet laureate, and it was his task to praise the deified emperor. The early Christians looked upon the theologian as the defender of Christ's deity. John, the author of the book of Revelation, is sometimes called John the Divine, that is, John the theologian, ostensibly because throughout Revelation he exalts Jesus as Lord. Theology, then, was looked upon in early times as a formal act of worship on the part of a writer on religious subjects. In the course of time, *theology* became the accepted technical name for the study of God and his concern for man.

Theology must be distinguished from the science of religion, which is concerned with the fundamental principles at work within man's religious life and is the study of man in worship rather than the study of the object he worships. Theology, on the other hand, is the study of the object of worship, God. In theology, then, God is central and man is considered only as the worshipper of God.

Theology is also to be distinguished from the philosophy of religion. These two disciplines are related to one another in much the same way as are questions and answers. The philosophy of religion asks such questions as the following: Is the universe meaningful? Does it have a purpose? Is the universe friendly toward the religious man? Is God as the supreme being the origin and end of dependent beings? Theology supplies the dogmatic answer to the profoundest questions of religion, replying that God is the first and originating cause, who brings into being all other existing things as dependent creatures, and that God as the supreme being is friendly toward man.

**The Content of Theology.** Within the science of theology the distinction is made between theology proper in the narrow sense and theology as it concerns God's special relation to man. Theology proper is the study of God with respect to his existence, nature, person or persons, purpose, and especially his relation to evil. Theology as including the relations of God to his creatures is divided into the following departments for special study: Anthropology, which is the study of man as to his origin, constitution, and destiny; Christology, which is the study of the person, the natures, and the purpose of Christ; Soteriology, which is the study of the application of salvation as obtained by Christ in his ministry through the operation of the Holy Spirit upon the redeemed individual; Eschatology, which is the study of the end of this present world and the nature of the new heaven and the new earth; Ecclesiology, which is the study of the Church as the divine institution; and Moral Theology, which concerns human acts as related by reason and faith to an ultimate supernatural end. In each one of these special fields the theologian begins with an empirical study of available material in order to discover the place of God in the life of man, God being the central object of study both in theology proper and in its several departments.

Theology recognizes three different ways of coming to a knowledge of God. Reason is the first way. Through his senses man comes into relationship with the physical world, and through his reasoning faculty he infers the existence of nonphysical being as the cause of the physical world. He then infers that God exists as the creator and sustainer of the natural world and that He is the first, necessary cause of all that exists. A theology constructed on this way of knowing God is called natural theology because it draws its data from natural reason. The second way of knowing God is by means of an immediate experience of God, which comes to man in much the same way as does experience of the physical world—not through the five physical senses, but through the so-called "spiritual sense." This spiritual experience is referred to under a variety of names, such as *feeling, intuition,* and *insight.* Theology constructed on knowledge of this kind is called mysticism. The third way of knowing God is through the compelling action of God, God revealing or disclosing himself to man by this action much as one person compels the attention of another. Theology established on this way of knowing God is called revealed theology; it questions in no way the validity of the other types of knowing, but it insists that a knowledge of God that springs from divine compulsion comes prior to all other knowledge concerning him.

**Christian Theology.** Christian theology differs from other theologies in its emphasis upon the revelation of God in Jesus Christ. According to Christianity, God has encountered men in various ways and at different times, but the unique and final revelation was made in the historic Jesus who lived in Palestine at the time of Pontius Pilate. This revelation is interpreted and attested by the prophets

and apostles in the Scriptures. Whereas other theologies are centered in God, Christian theology is centered in God and in Christ; it is also centered in the Bible, as containing the word of God.

From the very beginning of the history of Christian theology, theologians assumed that the authentic text of Church doctrine was to be found in the canonical writings delivered to the Church by the Apostles. The Church opposed every attempt to set this apostolic legacy aside, and the ecumenical Church of the fourth and fifth centuries accepted without question the apostolic authority. During these years and the centuries following, the Church called her councils to formulate her official doctrines—such as those of the Trinity, the Person and Natures of Christ, Grace and Free Will, and other disputed subjects—with the intention of expressing the teaching of the apostles in the language of the day. The teachings of the Church Fathers were subject to Scriptural verification; furthermore, when these teachings contained contradictions, as Abelard and others found that they sometimes did, the Scriptures were assumed to be an authentic test of the truth of the conflicting statements. The Protestant Reformers insisted that they were in agreement with the Fathers in so far as the latter were in accord with the Scriptures, but they firmly opposed certain practices and doctrines of the Church of their time because they believed them to be not in accord with the Scriptures. The validity of this belief was attacked, in turn, by the theologians of the Counter Reformation.

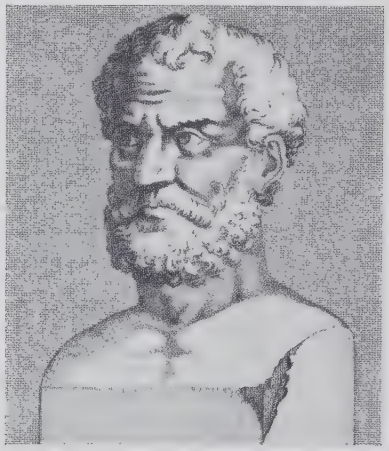
The father of the modern Protestant school of theology, F.E.D. Schleiermacher (1768-1834), under the influence of the scientific method, formulated a new conception of theology within Western Christendom. He substituted the individual's Christian experience for the Apostolic testimony as the source of theology. Man took the place of God at the center of study; psychology supplanted theology; the unchanging Christ gave way to the changing Christian experience. Thus theology was deprived of all objective truth in history. The followers of Schleiermacher were not slow to realize the implications of this conception of theology, and in succeeding generations they reduced Christian theology to an interesting ideology rooted and grounded in Christian culture.

This diversion of modern theology from the traditional genius of Christian theology was of only short duration. Within one hundred years of Schleiermacher's revolt against tradition, Karl Barth in 1919 published the first edition of his commentary on the epistle of Paul to the Romans, in which he urged the Church to turn back to the Scriptures as testifying to the revelation of God in Jesus Christ. Since the appearance of Barth's work there has been a general return on the part of Protestant theologians to the Word of God as the objective revelation of God. Theology must conform to the Word, *the Word* signifying God's encounter with man in the historic Christ. Contemporary trends in the Protestant churches are indicative of the popularity of this conception of Christian theology.

Roman Catholic theologians draw a sharp distinction between positive and speculative theology. Positive theology, thus distinguished, has as its aim to establish clearly which are the truths that God has revealed to man. Speculative theology has as its aim the understanding of revealed truths. A combination of the two is found in the scholastic theology of the Middle Ages, notably in the teachings of St. Thomas Aquinas (1225-1274).

There are in general four ways in which contemporary theologians express the genius of Christian theology. First, there are the traditionalist theologians, who teach that the meaning of the word of God is to be found in the writings of the great ecclesiastical tradition. The Roman Catholics turn primarily to Thomas Aquinas as a representative of this tradition; the Protestants hold the great Reformers, notably Martin Luther and John Calvin, in special regard. A second group are the Biblicists, who teach that the Word of God is found in the Bible alone. For these theologians the tradition must itself be checked as secondary to the Scriptures. The third group are the dialectical or crisis theologians, who emphasize the Word of God as God encountering man in Christ through the Scriptures, an experience attested by the Holy Spirit within the individual. The fourth group, to whom no name has become attached but who might be called the Churchmen, emphasize that it is the living Church of today which proclaims the Word of God to man. Theology, for this fourth group, becomes a criticism of, and a reflection upon, the utterances of the present-day Church as the voice of God in contemporary society. All four of these groups agree that God has revealed himself in Jesus Christ. They differ as to the form by which this revelation is declared to modern man, but they join with the Church Fathers in affirming that the heart of Christian theology is the revelation of God in Christ as confirmed by the Apostles in the Biblical record. *See also* BRAHMANISM; BUDDHISM; CHRISTIANITY; DOGMA; ISLAM; JUDAISM; RELIGION; THEISM. C. M. DeB.

**THEOPHRASTUS** [thi'ofra'stəs] (c. 370-287 B.C.), ancient Greek philosopher and scientist, was born in Eresus, Lesbos. He studied under Plato in Athens, then under Aristotle, whose close friend he became and whom he succeeded as head of the Peripatetic school in 323 B.C. His work paralleled Aristotle's in scope and scientific character. He wrote on metaphysics, logic, physics, zoology, botany, psychology, ethics, politics, civilization, religion, music, rhetoric, and education; and the specificity of his interests is indicated by titles that vary from Fire, Stones, Dizziness, and Intoxication, to Modes of Life, Piety, and Marriage. Most of his work is lost, but occasional large fragments provide a clear conception of its nature. His writings on plants, which remain, represent his most original scientific inquiry, the product of large-scale collection of materials, careful classification, and detailed study. Most popular of his surviving works is his *Characters,* a collection of thirty sketches of types such as the pretentious man, the arrogant, the distrustful, the surly, each delineated with masterful use of illuminating incident. The mean man, for example, when he goes abroad on public service, leaves at home the money given him by the state and



THEOPHRASTUS

CULVER SERVICE

borrows from his fellow-ambassadors; he keeps his sons home from school during February, which has many festivals, so that he can save the school fee.

Theophrastus worked essentially within the confines of the Aristotelian system, to expand the area of detailed knowledge. His spirit is critical, not slavish. In his analysis of nature and soul he is more naturalistic than his master; for example, he is more conscious of the difficulties in establishing a teleological view of nature. His ethics advocates the mean in conduct, happiness, friendship, and the intellectual life, and stresses the role of external factors as threats to peaceful contemplation. His life and character indicate that scientific activity was his supreme concern. A. E.

**THEORIES OF LANGUAGE ORIGIN.** The problem of the origin of language has occupied the minds of a great many eminent thinkers, from Plato and Aristotle to Ernest Renan and Otto Jespersen. The question was reexamined in full as late as 1946 in a book by G. Révész entitled *Ursprung und Vorgeschichte der Sprache,* but most twentieth-century linguists are inclined to regard the subject as wholly speculative and hypothetical or at least to dismiss it as lying outside the realm of linguistic science.

Until the end of the eighteenth century, three main theories on the origin of language divided the field of investigation: the traditional theological theory, based on the famous chapter of Genesis (xi) that describes the construction of the tower of Babel; the logical or conventionalistic theory, attributing the origin of language to an agreement among learned men to give a certain meaning to a certain word; and the theory of the "fantastic" origin of language, vaguely presented by Francis Bacon (1561-1626) and fully developed by G. B. Vico (1688-1744). G. B.

The theories discussed in more recent times can be roughly divided into two great classes, the biological and the anthropological. This division is fundamentally connected with a discussion once conducted among Greek philosophers, on the point of whether language existed by nature (*φύσει*) or by convention (*θέσει*). Adherents of the biological theories seek the origin of language in the tendencies and characteristics of the animal world; adherents of the anthropological theories, starting from the assumption that language is a purely human phenomenon, look in the history of language itself for its most archaic constitutive elements and concentrate especially on the speech of "primitive" tribes.

**Biological Theories.** The principal biological theories fall into two classes:

1. The theory of "expressive gestures and sounds" derives language from the "natural movements that express passions" (Descartes). Since interjections supply important evidence for this view, it is sometimes called the "interjectional" theory and sometimes, jocularly, the "pooh-pooh" theory.

2. The theory of "animal sounds" seeks analogies to the origin of the human language in the sounds emitted by animals, especially in those that can be observed in the study of apes.

**Anthropological Theories.** The principal anthropological theories are more numerous:

1. The "imitation" or "onomatopoeia" theory holds that all human language derives from the imitation of natural sounds (thunder, rain, cries of animals, etc.). This theory is sometimes called derisively the "bow-wow" theory.

2. The "babble" theory seeks the origin of language in the spontaneous babbling of children. Words like *daddy, mammy, pop, mom,* and many others are adduced in support of this view.

3. The "reflex" or "response" theory regards language as originally the emission of sounds in immediate, mechanical response to special external stimuli. It is frequently called the "ding-dong" theory.

4. The "song" theory, accepted by most of the ancient Greek philosophers and by many moderns, holds that singing was the original form of language.

5. The "disposition" or "function" theory assumes that man must have had some special disposition to speak before he began speaking and asserts, as one consequence of this assumption, that the capacity for logical thinking must have preceded language.

6. The "gesture-language" theory, which is one of the most popular, postulates that for countless ages before language came into existence man communicated through gestures alone. J. J. A. van Ginneken, the Dutch linguist, dates the beginning of oral language at 3500 B.C. at the earliest, maintaining that up to that time men expressed themselves by gestures or by the interjectional "clicks" which still exist in South African languages. In support of this theory it is argued that the higher apes learn gestures easily, that some primitive tribes express themselves better through gestures than through oral language, and that a gesture-language exists in actuality, namely, the language of mutes.

7. The "symbolical" theory, advanced by Suzanne K. Langer (*Philosophy in a New Key,* 1948), regards language as a form of symbolism. In this view, values are attached to objects, pictures, and sounds, and these values are symbolically expressed in language.

8. The "utilitarian" theory maintains that language originated from the practical necessities of human co-operation. This theory, which was defended by the Roman poet Horace, now has no important support among linguists or philosophers.

9. The "deception" theory is presented by E. H. Sturtevant in *An Introduction to Linguistic Science* (1947). Observing that voluntary communication can scarcely have been called upon except to deceive, Sturtevant concludes that "language must have been invented for the purpose of lying." This theory has been criticized as ruling out the factor of emotional stress in human utterances.

10. The "contact" theory, proposed by G. Révész, emphasizes the relation of the individual to a social unity. It regards language as the result of an innate trend in all social creatures toward reciprocal approach, contact, and understanding.

**Philosophical Theories.** The philosophical theories on the origin of languages may be divided into two main classes; the nativist and the empiricist, a division which corresponds roughly to that between the biological and the anthropological theories. The nativist theories maintain that the capacity of speaking is innate in man and therefore precedes experience; among the principal adherents of this view are W. von Humboldt, Max Müller, and Ernest Renan. The empiricist theories attribute the decisive influence, even in the first stages of language, to human experience, will, and thought; this is the view of Condillac, Hobbes, and Darwin, among others. The nativists incline to make of language an inevitable product of human tendencies, whereas the empiricists consider it a product of conscious choice. The nativists concentrate their attention on the way in which language originated; the empiricists stress the way in which it developed.

The issue between nativists and empiricists might be settled if there were enough evidence regarding persons who have grown to maturity without any contact with human

speakers. Four important cases have been recorded: Peter, "the Wild Boy," who was found in Hannover, Germany, in 1723; Victor, "the Savage of Aveyron," who lived alone in southern France at the end of the eighteenth century; and two girls, Amala and Kamala, who were found near Midnapur, India, in 1920. None of these spoke in isolation a language of any kind, and Victor never learned to speak at all, though he succeeded in mastering the alphabet of the deaf mutes.

**Theological Theories.** The theological theories of the origin of language maintain that language is a gift from God, or that it is the product of a wisdom inherent in nature through the will of God. Among the most famous followers of these theories may be mentioned Abelard, Duns Scotus, Jacob Grimm, and W. D. Whitney. For those who define language as a system of signs that express ideas, or as a logical structure, or as a way of thinking, a theological explanation of the origin of language is especially useful in order to bridge the gap that exists, in their conceptions, between the animal world and the world of humans. Those on the other hand who believe, with Croce and Vico, that language is expression, regard it as a product of natural tendencies.

**Methods of Study.** Several methods of study are open to the student of language origin. Some study the language of children, seeking in their utterances the most primitive forms of language, just as Darwinists try to reconstruct the history of the human and animal species in the successive transformations of the fetus. Some seek the early stages of speech in the "archaic" languages of primitive tribes; their studies have resulted in valuable discoveries, but it is probable that even the most primitive languages have a long history behind them. Others look to the careful study of languages in general for light on the origin of language; the study of Indo-European languages, for example, shows that the linguistic categories of the article and the adjective, and probably also the adverb and the conjunction, are of late creation, whereas nouns, verbs, and interjections are very old. Still others study the language of aphasiacs, applying the principle that sufferers from aphasia lose the elements of language in an order inverse to that in which they acquired them. Adherents of the biological theories of language origin enter still another field in their investigation, studying the gestures and utterances of the animal world. G. B.

**THEORY,** in music, basically the rudiments or elements of music, starting with the study of notation, key signatures, scales, musical terms, solfeggio, and sight-singing. The next step in order of difficulty is harmony, which consists of exercises in part-writing, correlated work at the keyboard, and harmonic analysis. Later comes the study of the polyphonic style in counterpoint, followed by a study of the canon and the fugue, an analysis of musical form and composition in homophonic forms for piano or small ensemble, and orchestration, including both analysis and scoring. A knowledge of all these elements is necessary to advanced composition for full orchestra. J. M. Ba.

**THEOS.** *See* Antiochus.

**THEOSOPHY** [thiɒ'sofi] (fr. Gr. *θεός*, God, and *σοφια*, wisdom), the name of a body of teachings, offering an explanation of the source and purpose of life. Its survey includes both anthropogenesis and cosmogenesis, linking into an orderly scheme of evolution, governed by absolute law, all of life, both material and spiritual. The concepts of theosophy may be traced in philosophical writings such as those of Plato, Plotinus, and the Christian Gnostics, and more directly in the scriptures of the world's great religions, particularly those of India, China, and Egypt. Theosophy is sometimes referred to as the Ancient Wisdom, or the Wisdom Religion.

The following concepts are basic to Theosophy: (1) there is postulated a First Cause which is eternal, unborn, and undying; it is the boundless and immutable principle, the infinite reality within which all manifestation has its being; (2) the primordial Source mirrors itself in the created universe, thus becoming the manifested God, or Logos; (3) from the causeless One Cause, the universe appears as cosmic Ideation from which proceeds the duality, spirit-matter, thence the trinity of spirit, matter, and the relationship between the two, or consciousness; (4) existing within the manifested consciousness, yet differentiated, are the myriad units of consciousness, each of which is a Divine Son, or Monad; (5) the cosmic purpose of the Monads is to evolve innate powers of conscious divinity by experiencing the limitations and mastering the environments of denser matter in the mineral, vegetable, and animal kingdoms of life; theosophy conceives that there is an evolution of consciousness paralleling the evolution of form, and that upon reaching the human stage, the Monad's destiny can be more swiftly accomplished as intelligent co-operation is awakened; (6) the Monad is man's immortal element of consciousness whose potentialities are being gradually released through cycles of reincarnation; (7) reincarnation is perceived as an orderly, periodic withdrawal and reappearance of man's Higher Self into mortal vestures; these vehicles of mind, emotion, and physical body afford further opportunity for experience and growth; (8) the cyclic recurrence of man's spirit in material form is determined by Karma, the law of action and reaction governing with perfect justice all events in the universe; and (9) the fruition of human experience is the illumined realization of the One Life, the recognition of which constitutes spiritual wisdom and provides the basis of ethics which guarantee that the awakened powers will be used to forward and not obstruct the evolutionary process; beyond that stage of fulfillment the destiny of man's spirit is infinite progress in the perfection of his divine nature.

The modern revival of theosophical thought began with the establishment of The Theosophical Society in New York City on Nov. 17, 1875, by Helena Petrovna Blavatsky, Colonel Henry Steel Olcott, William Q. Judge, and others. Colonel Olcott became the Society's first president and Mme. Blavatsky its first recording secretary. Though numerically small at first, the Society has grown into an international body organized in over fifty countries, with international headquarters at Adyar, Madras, India. The Society has developed an extensive literature, chief among which is Mme. Blavatsky's *The Secret Doctrine*. Succeeding Presidents Annie Besant (1907-1933), George S. Arundale (1933-1945) and C. Jinarajadasa (1946- ) have contributed further important works. The three objects of the Society are: (1) to form a nucleus of the universal brotherhood of humanity, without distinction of race, creed, sex, caste, or color; (2) to encourage the study of comparative religion, philosophy, and science; (3) to investigate the unexplained laws of nature and the powers latent in man. J. S. P.

**THEOTOKOPOULOS, KYRIAKOS.** *See* Greco, El.

**THE PAS.** *See* Pas, The.

**THERAPEUTAE** [therəpyu'ti], a religious sect which flourished in the first century of the Christian Era and is

described, among contemporary sources, only in Philo's *De vita contemplativa.* Strictly ascetic, the Therapeutae lived in separate cells where they spent the day in prayer, meditation, and study. They ate sparingly and only in the evening. Virgins were admitted to the group, but they sat apart in the dining quarters and did not mingle with the men. On the Sabbath the members met for a communal meal and discussion. A feature of their observances was a nocturnal celebration, at which they spent the whole night singing religious songs; it is not clear, however, whether this celebration was held every seven weeks or only on the principal Jewish festivals (Passover, Pentecost, and the Feast of Tabernacles). The Therapeutae had much in common with Christian monastic orders, and some scholars have suggested that they may have been Christians, but most maintain that they were a strictly Jewish sect, akin to the Essenes, from whom they may have separated. H. Bl.

**THÉRÈSE OF THE CHILD JESUS, ST.** [te′rɛ′z] (1873-1897), French virgin saint, was born Marie Françoise Thérèse Martin at Alençon in Normandy. At the age of fifteen she entered the Carmelite convent at Lisieux, where

ST. THÉRÈSE OF THE CHILD JESUS

BROWN BROTHERS

she later held for a few years the office of mistress of novices. Her autobiography (*L'Histoire d'une âme*) combines a delightful freshness of outlook with great depth of spiritual insight. Though professing herself "a very little soul, who can only offer very little things to our Lord," Thérèse Martin was generally acclaimed a saint shortly after her early death. She was beatified in 1923 and canonized in 1925. Her deathbed promise, "I will spend my Heaven in doing good upon earth," has been seen fulfilled in numberless miracles attributed to her intercession. Patroness of foreign missions, she is commemorated October 3; in her honor have been dedicated many churches and shrines throughout the world, often under the title of the "Little Flower." W. C.

**THERMOCHEMISTRY,** a study concerned with heat accompanying chemical change.

**Kinetic Nature of Heat.** At absolute zero, there is practically no motion of molecules, or of atoms within them. As the temperature is raised, the atoms begin to vibrate. At still higher temperatures, rotation and eventually translation of the molecule through space takes place. Energy is also stored up within the particle as electronic energy by having its electrons in certain excited energy levels. The sum of these energies makes up the temperature of the particle. In other words, heat is a form of motion, and the Kinetic-Molecular theory postulates that the kinetic energy of a particle varies directly as the temperature, i.e., $\frac{1}{2}mv^2 \propto T$, for a particle of mass $m$, moving with velocity $v$, at absolute temperature $T$. From this is deduced the gas law expression for $n$ molecules that: $PV = kT = \frac{1}{3}\ nmv^2$.

**Endothermic and Exothermic Reactions.** Chemical reactions either liberate heat (exothermic) or consume it (endothermic). Reactions of the former type are far more abundant. The first example below shows that when 2 moles of gaseous hydrogen (2 x 2.016 grams) combine with 1 mole of gaseous oxygen (32 grams) to give 2 moles of liquid water (2 x 18.016 grams) sufficient energy is liberated to raise 136,828 grams of water one degree.

*Exothermic Reactions:*

$$2H_2(g) + O_2(g) \longrightarrow 2H_2O(l) + 136{,}828 \text{ cals.}$$

$$C(s) + O_2(g) \longrightarrow CO_2(g) + 94{,}400 \text{ cals.}$$

$$HCl(aq) + NaOH(aq) \longrightarrow NaCl(aq) + H_2O(aq) + 13{,}880 \text{ cals.}$$

$$Fe_2O_3 + 2Al \longrightarrow 2Fe + Al_2O_3 + 198{,}800 \text{ cals.}$$

*Endothermic Reactions:*

$$H_2 + I_2 \longrightarrow 2HI - 12{,}000 \text{ cals.}$$

$$N_2 + O_2 \longrightarrow 2NO - 43{,}000 \text{ cals.}$$

At one time, Thomsen and Berthelot (1854) wrongly postulated that exothermicity was an index of how fast a reaction would occur. Such a theory left no possibility of endothermic reactions; it was eventually disproved.

**Heats of Combustion.** The heats of reaction between a great many organic compounds and oxygen have been carefully measured; these have thrown much light on the forces binding atoms together. Heats of combustion per mole at 18°C. are 783,400 cals. for benzene, 1,349,600 cals. for cane sugar, and 170,900 cals. for methyl alcohol.

**Hess's Law of Constant Heat of Reaction.** Hess enunciated, in 1840, that the heat evolved in changing from state $A$ to state $B$ is the same irrespective of the mode of change. This law enables one to utilize heats of formation of substances in calculating their heats of reaction. For instance, heat of combustion for $2Al$ is 389,500 cals., and for $2Fe$ is 190,700 cals. From this it is seen that the reaction $Fe_2O_3 + 2Al \longrightarrow 2Fe + Al_2O_3$, which involves, first, the breaking of the iron-oxygen bonds (-190,700 cals.); then the formation of aluminum-oxygen bonds (+ 389,500 cals.) should give a heat of reaction of (389,500 — 190,700) = 198,800 cals. *See also* HEAT AND THERMODYNAMICS. H. N. A.

**THERMOCOUPLE.** *See* ASTRONOMICAL INSTRUMENTS (*Astrophotography*); HEAT AND THERMODYNAMICS (*Measurement of Temperature*).

**THERMODYNAMICS.** *See* HEAT AND THERMODYNAMICS.

**THERMOMETRIC TITRATION.** *See* ANALYTICAL CHEMISTRY (*Physicochemical Methods*).

**THERMOPYLAE** [thərmɒ′pili], a famous pass between Thessaly and Locris in ancient Greece which was the main

gateway from the north to central Greece. In antiquity the pass was long and narrow, with the sea on the east and high cliffs along the opposite side. It was here in 480 B.C. that the Spartans under Leonidas and their Greek allies made their historic ten-day stand against a numerically superior Persian force, only to be overwhelmed when a traitor guided a portion of the Persian army around Thermopylae by a little-known mountain road. A similar battle for the pass occurred in 279 B.C., when the Gauls under Brennus defeated the defending Greeks just as the Persians had done in 480. In the next century, Antiochus III, the Seleucid king, attempted to hold the pass against the Romans (191 B.C.), but on this occasion the Romans were successful in forcing the pass by a frontal attack. In modern times the pass has been considerably widened, and its appearance is quite different from what it was in the days of Leonidas. T. B. J.

**THERMOSTATS,** self-operating devices for controlling temperatures, applied first to gas water heaters in 1897 and then to gas ovens in 1915. Soon, thereafter, similar devices were used for the control of house heating and were applied to safety pilot burners (thermostatic safety pilots).

The principle of operation involves the differential expansion of two metals, as the bimetallic strips and "rod in tube", or of liquid in a metal bulb and tube. In the former, the movement is applied directly to the valve mechanism regulating the fuel; in the latter, the force of the expanding liquid is transmitted through a metallic bellows to the mechanism. F. Wi.

**THERSITES** [thərsai′tiz], in Greek legend, an ugly and insolent warrior in the Greek forces at Troy and the son of Agrius. He bitterly attacked Agamemnon in the assembly following Achilles' withdrawal from fighting and was chastised for this behavior by Odysseus. Later he mocked Achilles for mourning over Penthesilea's death, and Achilles slew him in anger. *See also* TROILUS AND CRESSIDA. G. E. D.

**THESEUS** [thi′sus], in Greek legend, the great hero of the Athenians, the son of Aegeus, king of Athens, and Aethra, daughter of King Pittheus of Troezen. Theseus was born when Aegeus, being childless, visited Pittheus, who arranged for him to have intercourse with his daughter. Another version relates that Theseus was the son of Aethra and the god Poseidon, and modern writers suggest that Aegeus was a local form of Poseidon himself. Theseus grew to maturity at Troezen and set out for Athens, taking the sword and sandals left behind by Aegeus. On the way he destroyed many robbers and monsters, his deeds recalling the more illustrious ones of Heracles. Theseus' adventures included the killing of four notable malefactors: the brigand Periphetes; Sinis, who tied people to two pine-trees bent together and tore his victims apart by releasing the trees; Sciron, who kicked people into the sea; and Procrustes, who fitted his victims to a bed by stretching or cutting off their limbs.

When Theseus arrived at Athens, Medea, his father's wife, attempted to poison him, but Aegeus, recognizing the sword as his own, acknowledged the youth as his son and successor. Theseus' next exploit was to capture the fire-breathing bull of Marathon, which Heracles had brought from Crete. Then he went to Crete as one of the groups of youths and maidens offered each year to the Minotaur. On the way, Minos, who was conducting them, threw overboard a gold ring and challenged Theseus, if he were really the son of Poseidon, to jump overboard and bring it back; Theseus not only returned with the ring, but also brought back a golden crown which he had received from Amphitrite. At Crete Theseus slew the Minotaur with the assistance of Ariadne, the daughter of Minos, and fled with her by sea, deserting her later on the island of Naxos. He had promised Aegeus to hoist a white sail if he returned safely; but he forgot his promise as he approached Attica, and Aegeus, perceiving the black sail and believing that Theseus had perished, hurled himself from a rock to his death. Theseus thus became king of Athens.

The hero took part in numerous legendary exploits, the voyage of the Argonauts, for example, and the Calydonian hunt. He also made an expedition against the Amazons, carrying off their princess, Antiope, and defeating the Amazon invasion of Attica which followed this exploit. By Antiope Theseus had a son, Hippolytus, and after Antiope's death he married Phaedra, another daughter of Minos. He formed a firm friendship with Pirithous, king of the Lapithae, and aided him in a fight against the Centaurs. With Pirithous he visited Sparta and carried off Helen, who was later rescued by her brothers Castor and Pollux, and he joined Pirithous in a trip to the underworld when the latter desired to abduct Persephone. Both heroes were imprisoned in the lower world, but Theseus was later rescued by Heracles.

During Theseus' absence from Athens, Phaedra fell in love with Hippolytus, who had devoted himself to Artemis and a life of chastity. When her love was repulsed, she committed suicide and left behind a false accusation of Hippolytus. On his return Theseus accordingly cursed his son, and, since Poseidon had granted him the fulfillment of three wishes, the curse was effective: Hippolytus was dragged to death by his horses, which were frightened by a monster sent by Poseidon from the sea. Theseus, unable to re-establish his authority after his return, went to Scyros, where he was slain by King Lycomedes. The Athenians believed that their dead hero reappeared and aided them at the Battle of Marathon. *See also* AMAZONS; ARIADNE; MINOTAUR; PIRITHOUS. G. E. D.

**THESPIS** [thɛ′spɪs], Greek dramatist, reputed father of Attic tragedy, was born in Icaria, a village in Attica, and flourished in the sixth century B.C. No part of his works is extant. He is supposed to have created tragic drama by introducing an actor with a speaking part, impersonating a legendary or historical character, into a performance which had previously been rendered by a chorus alone. According to one ancient authority, Thespis took the actor's part himself. He is also credited with having initiated the use of linen masks on the stage. It may be, as Horace suggested, that he took his plays about on wagons to local festivals. It is possible that he gave his first performance at Icaria, and probable that he gave performances at Athens before dramatic competitions were organized there. His first performance at Athens may have been as early as 560 B.C. He is supposed to have won his first victory in the competitions at Athens in 534 B.C., probably at the Great Dionysia festival. S. D. At.

**THESSALONÍKI** or **SALONIKA** [thɛ′sɑlɔnyi′ki, sæ′-lɔni′kə], the capital and chief port of the department of the same name in Greek Macedonia on the Gulf of Thessaloníki, east of the Axiós River delta. The center of convergence for some of the most important routes crossing the Balkan Peninsula, it has suffered from many invasions. St. Paul visited the city and addressed to converts there his Epistles to

the Thessalonians. Thessaloníki was taken by the Saracens in 904 and by the Normans in 1185. During the Middle Ages it was part of the Byzantine Empire and in the thirteenth century was capital of the kingdom of Thessalonica created by Baldwin I, Emperor of Constantinople, for Boniface III, Count of Montferrat, who ruled Greece and Macedonia. It was under Turkish rule from 1430 to 1912, when it became part of Greece. An Allied base in World War I, the city was destroyed by fire in 1917 and was rebuilt by refugees. Reclamation of neighboring marshland was begun in 1935. During World War II, the city was occupied by the Germans from April 1941 to October 1944. The port has free-trade facilities and the city is an important industrial center. The manufacture of carpets, textiles (cotton, silk, and wool), flour, jute sacks, machinery, leather goods, and tobacco are the major industrial enterprises. Pop. 1951, 217,049.

The department of Thessaloníki, with an area of 2,436 sq. mi., is bounded by Yugoslavia and Bulgaria on the north, the Aegean Sea on the south, and by the departments of Sérrai on the east, Lárisa on the south, and Flórina and Kozáni on the west. The Khalkidhikí Peninsula lies southeast of the city of Thessaloníki. Pop. 1951, 458,271. S. Van V.

**THESSALONÍKI (SALONIKA), GULF OF,** or **GULF OF THERMAIKOS,** in the northwestern part of the Aegean Sea, between Thessaly and the Khalkidhikí Peninsula. The gulf is about 30 mi. wide in the south, but narrows to 10 mi. near the harbor of Thessaloníki. The northern shore is the low, malaria-infected delta of the Axiós (Vardar) and Alíakmon (Vistritsa) rivers. Thessaloníki, the chief seaport of Greek Macedonia, is situated at the head of the gulf.

**THESSALY** [thɛ'səli], a division of ancient Greece, located on the east coast and bounded on the north by Macedonia, on the west by Epirus, on the south by Doris and Locris, and on the east by the Aegean Sea. Although Thessaly contained much rugged and mountainous country, there were also large fertile plains. The country was not politically unified during the Classical period until it came under the influence of the Macedonians in the fourth century B.C.; two centuries later, it became a Roman province. The Thessalians were slow to become civilized; although the agricultural output of Thessaly must have been considerable, the region was chiefly known for horses. Modern Thessaly roughly corresponds to the ancient division and includes the departments of Lárisa, Kardhítsa, Magnisía, and Tríkkala. It was ceded to the Greek kingdom in 1881. T. B. J.

**THETFORD MINES** [thɛt'fərd], a city in Megantic Co., Quebec, Canada, situated on Highway 1, about 70 mi. south of the city of Quebec. About 85 per cent of the world's supply of asbestos is mined in the environs, as are considerable quantities of talc and chromic iron. Thetford Mines has several industrial establishments, including foundries and asbestos, sash and door, and cement-block factories. The city was incorporated in 1912, and is served by the Quebec Central Railway. Pop. 1951, 15,095. D. F. P.

**THETIS** [thi'tɪs], in Greek mythology, a sea goddess, the daughter of Nereus and Doris. Like the other Nereids she dwelt in the sea. Both Zeus and Poseidon wooed her until they learned that her son was fated to be mightier than his father. Thetis was then wedded to Peleus, after he had managed to hold her through a series of rapid transformations. It was at their wedding celebration that Eris threw the golden apple among the assembled gods. The famous son of Thetis was Achilles. *See also* ACHILLES; PELEUS; TROJAN WAR. G. E. D.

**THIARD (or TYARD) PONTUS DE** [tya'r] (1521-1603), French poet, was born in Bissy, Saône-et-Loire, France, in 1521. His first book of poems, *Les Erreurs amoureuses* (1549), appeared just before Du Bellay's *Deffense et illustration de la langue françoyse,* which served as the rallying point about which the Pléiade was formed, and Thiard was immediately adopted as a member of that group. While most of the other members belonged to the Loire region and Paris, Thiard's literary activity centered around Lyon, where interest in philosophy was strong. The Platonists were especially influential, and Thiard was drawn into this school of philosophical writing. In 1551 he translated a curious book, of Platonic inspiration, by a Portuguese Jew writing in Italian; this book, under the title of *Leon Hébrieu de l'amour,* Thiard dedicated to the king. Following this, he wrote six *Discours philosophiques* between 1552 and 1556, describing his theory of poetical frenzy and the then popular concept of an alliance between poetry and music. His later work includes *Nouvelles oeuvres poetiques* (1573) and *Douze fables des fleuves et fontaines* (1585).

In his middle years Thiard had already begun to move away from poetical writing, and in this evolution from a nearly pagan Renaissance attitude to a Christian spirituality he anticipated one of the trends of the coming Classical period. In 1552 he had become canon of St. Vincent Cathedral in Mâcon, and in 1578 he became bishop of Chalon-sur-Saône, where he died in 1603, the last survivor of the Pléiade. His poetry, much admired in his day, now seems obscure and artificial. H. F. M.

**THIBAULT, JACQUES ANATOLE.** *See* FRANCE, ANATOLE.

**THIBODAUX** [tɪ'bodo'], a town in southeastern Louisiana, the parish seat of Lafourche Parish, situated on Bayou Lafourche, in a flat section surrounded by lakes and bayous, 45 mi. southwest of New Orleans. Natural local resources include oil, gas, and timber. Thibodaux was founded in 1801 by Henry Schuyler Thibodaux, after whom it was named, and it was incorporated as a town in 1830. The local government is the commission type. Thibodaux is on the site of the old Spanish Trail. Of historic interest are the Rienzi Plantation, established in 1796 by Queen Maria Louisa of Spain, and the Acadia Plantation, used during the Civil War as a camp for Federal forces. The town is the birthplace of Edward Douglass White, Chief Justice of the United States Supreme Court from 1910 to 1921. Transportation is supplied by the Southern Pacific and the Texas and Pacific railroads. Sugar cane, the chief crop of the surrounding farm area, has determined the town's principal industries: sugar refining and the manufacture of farm machines, particularly those used for cane harvesting. Pop. 1950, 7,730.

**THIEF RIVER FALLS,** a city in northwestern Minnesota, the county seat of Pennington Co., situated at the confluence of the Thief and Red Lake rivers, about 75 mi. northwest of Bemidji. It is a distributing center, handling groceries, fruit, poultry, and dairy products for the surrounding farm area, and its manufactures include butter, cheese, and soft drinks. It was incorporated in 1896. The city is governed by a mayor and city council. Thief River Falls was once called Rockstad. In City Park at the junction of the Red Lake

and Thief rivers, are the ruins of an old Indian settlement. The city is served by the Great Northern and the Minneapolis, St. Paul & Sault Ste. Marie railroads. Pop. 1950, 6,926.

**THIEL COLLEGE** [ti'l], an accredited, coeducational, privately controlled college of arts and sciences affiliated with the United Lutheran Church in America. It was founded in 1866 and the charter was granted in 1870. The 34-acre campus is located in Greenville, Pa. The degrees offered include the A.B. in liberal arts and the B.S. in business administration. Some dormitories have been provided for men and women. Additional living accommodations for men are provided by fraternities. Scholarships are available, and there is a small loan fund. Opportunities for self-help enable some of the students to earn part of their expenses. *For statistics see* COLLEGES AND UNIVERSITIES. J. R. To.

**THIERS, LOUIS ADOLPHE** [tyɛ'r] (1797-1877), French statesman and writer, was born in Marseille, Apr. 16, 1797. He studied law at Aix and was admitted to the bar in 1821. In 1822 he began to direct the Paris newspaper, *Constitutionnel,* and in 1829 helped to found the *National,* a paper that helped to foment the Revolution of 1830. Thiers was elected to the House of Deputies in 1830 and two years later became minister of the interior. He was elected to the French Academy in 1833 and in 1836 became premier, but clashed with the king, Louis Philippe, and as a consequence resigned. He resumed his campaign of parliamentary opposition and became president of the council and minister of foreign affairs four years later, but was again forced out of office. He spent the next two decades in virtual retirement, including a brief period of imprisonment and exile after the *coup d'état* of 1852 by which Louis Napoleon became Emperor Napoleon III. Thiers returned to politics in 1863, was elected to the House of Deputies, and for the next seven years led the small party of anti-Imperialists.

The rise of Germany prompted Thiers to counsel moderation until France could acquire sufficient strength to risk a conflict. When Napoleon's defeat at Metz and his surrender at Sedan were followed by the establishment of the Third French Republic, Sept. 4, 1870, Thiers was chosen to be the first president of the new republic. The Paris Commune later opposed him and seized the capital, and only after considerable fighting were the forces of the National Assembly, directed by Thiers, able to reassert governmental authority. Thiers then agreed to the humiliating German peace treaty. Despite his efforts to restore order and prosperity, he met considerable opposition and in May 1873 was forced to resign and retire to private life.

Thiers' literary fame rests on two works. The pro-Napoleonic *Histoire de la révolution française* (10 vols., 1823-1827) was published before he was thirty. His *Histoire du Consulat et de l'Empire* (20 vols., 1845-1861) was written in the years of his retirement from public life. Thiers died in Paris, Sept. 3, 1877. T. R. H.

**THIRD ESTATE.** *See* ESTATES GENERAL.

**THIRD INTERNATIONAL (COMINTERN)** [kɒ'mɪntɜ'rn], an organization of Communist parties founded in Moscow in March 1919 and formally disbanded in May 1943. Its predecessors were a short-lived International Workingman's Association, established in 1864, and the Second, or Socialist, International, formed in 1889. The latter, a federation of the socialist and labor parties of many countries, wielded considerable influence in European politics until it was disrupted by internal conflicts over the question of participation in World War I. The Communist International, or Comintern, was created by the Bolsheviks, led by Lenin, when they found they could not dominate efforts to revive the Second International. The Comintern displayed the central authoritarianism that characterizes the Russian Communist Party. To a large extent it was supported financially by the Soviet government, and its leadership was almost wholly the same as that of the Soviet Union. The Comintern was conspicuously less representative of the proletariat than of the revolutionary-minded intelligentsia. Only briefly was the Comintern devoted overtly and primarily to the cause of promoting proletarian revolutions in other countries. Its major effort, which took place in China in the 1920's, failed. During most of its existence it was almost exclusively an instrument of Russian foreign policy. Communists in other countries were instructed to join trade unions and other organizations so as to influence their actions, as desired by the Soviet Union. That the control of Russian Communists over the Communist parties of other countries relaxed after World War II was confirmed in October 1947 by the formation of the Communist Information Bureau, or "Little Comintern," to co-ordinate the activities of European Communist parties. V. B. Z.

**THIRTY-NINE ARTICLES OF THE ANGLICAN CHURCH, THE,** a confession of faith, related to various other confessions of faith, among them the Helvetic, the French (Gallic), the Belgic, and the Scottish. All of these, prepared in the sixteenth and seventeenth centuries, set forth, as against Rome, what the churches of the Reformation believe and teach. The Thirty-Nine Articles, called in the Prayer Book the "Articles of Religion," were drawn up in 1563, the fifth year of Elizabeth's reign; they were a careful revision of the articles, forty-two in number, which had been prepared largely by Archbishop Cranmer in 1552, during the reign of Edward VI, which were in turn a revision of articles of the same number prepared by Cranmer two years earlier. Charles Hardwick, in his *History of the Articles of Religion,* shows conclusively that Cranmer was greatly influenced by the Augsburg Confession; the Thirty-Nine Articles reflect the same dependence, though in matters upon which the two enumerations differ, the Thirty-Nine Articles are apparently more influenced by the Confession of Württemberg. Finally, the Thirty-Nine Articles, though they largely reflect Lutheran doctrine, on the question of the Lord's Supper favor rather the position of the Reformed Church.

The first five articles are concerned with the Holy Trinity. Articles Six and Seven define the inspiration of the Scriptures, and list the books of the Old and New Testaments and the Apocrypha. Article Eight affirms the acceptance of the Nicene, the Athanasian, and the Apostles' creeds. Articles Nine through Eighteen deal with various aspects of the working of God's saving grace, with original sin, free will, justification, good works, works of supererogation, the sinlessness of Christ, sin after baptism, predestination and election, and salvation only by the name of Christ. Articles Nineteen through Thirty-Six are concerned with the Church and its authority, the sacraments, the ministry, general councils, purgatory, the marriage of priests, excommunication, traditions in the Church, homilies, and the consecration of bishops and ministers. The last three articles concern the relation of Church and State, maintaining that the Queen's Majesty "hath the chief power" in matters civil and ecclesiastical; that the holding of private property is Christian; and that the tak-

ing of oaths ("when the magistrate doth require") is lawful for a Christian.

While the articles definitely repudiate Romanism, approving, for example, the marriage of priests, denying transubstantiation, rejecting the authority of tradition, and strongly asserting that "the Bishop of Rome hath no jurisdiction in this Realm of England," they equally firmly assert that the Church of England is a product of historical Christianity, and that, in fact, it adheres to the primitive faith of the Church and is in no way revolutionary. While the manner of wording of those articles on predestination and election allows of a Calvinistic interpretation, an Arminian would have no difficulty in reconciling himself to their teaching. The articles are strongly on the side of law and order, repudiating vigorously the communistic leanings of Anabaptism. Nothing is said in the articles about the doctrine of apostolic succession; Article Thirty-Six asserts that the ordination of all those in clerical orders who were consecrated according to the rites laid down in Cranmer's Prayer Book in the third year of Edward VI is both valid and regular.

The outstanding characteristic of these articles is their moderation. The Church of England is Protestant, but definitely catholic too, not in the Roman sense, but catholic in that it makes up a continuous part of the long history of the church universal. It therefore can make its appeal to the moderates of both groups, Roman Catholic and Protestant alike. M. J. H.

**THIRTY YEARS' WAR,** the term applied to the conflict originating within the territory of the Holy Roman Empire in 1618 and ultimately involving almost all of the Continental powers. The war perpetuated the disunity and chaos characteristic of Central European politics since the sixteenth century and made permanent the split between Protestant and Catholic Europe originating in the Reformation. France emerged as the leading Continental power, while Spain relinquished the military supremacy she had enjoyed for over a century.

The character of the war, with its strange admixture of political and religious motives, is clearly foreshadowed in its origins. Bohemia, which had been ruled by the Hapsburgs since the sixteenth century, was in the midst of a national and religious revival under the leadership of the strongly Protestant and fiercely patriotic local nobility. The latter refused to elect Ferdinand of Austria to the Bohemian throne and offered it instead to the Protestant Count Palatine Frederick. The latter accepted the offer and thus precipitated a war involving the member states of the Holy Roman Empire. Catholic Germany, in conjunction with the armies of Hapsburg Spain, succeeded in defeating the Bohemians at White Mountain in 1620. As a result the Bohemian crown was conferred on the Emperor, and it seemed as if the war were about to end. At this point, however, began the first of the foreign interventions which were to keep the conflict raging for another twenty-five years. First Christian IV of Denmark invaded Germany in 1625 as the protector of Protestant interests, but the Imperial armies under Tilly and Wallenstein inflicted a series of reverses on the Danish army, and by 1627 it seemed that the Holy Roman Emperor was about to re-establish a new and unified German state. His unfortunate policy of restitution and restoration of Church lands, however, led to alarm among the hitherto neutral Protestant princes and drew Gustavus Adolphus of Sweden into the conflict as the champion of the Protestant party. From 1631 to 1632 the Swedish army marched victoriously over Germany, defeating the best troops of the Emperor and giving new strength to the Protestant cause, but with the death of Gustavus Adolphus at the Battle of Lützen in 1632 the Protestant fortunes suffered a heavy and seemingly irreparable loss.

At this point France, then under the guidance of Richelieu, entered the war on the Protestant side. Richelieu was not motivated, needless to say, by any affection for Protestantism. He saw rather an opportunity to defeat the Spanish and Austrian Hapsburgs, the traditional enemies of France, and he did not hesitate to avail himself of this opportunity. For the next fifteen years French, Spanish, Swedish, and German troops fought in Germany, Italy, Flanders, and the Pyrenees, and the two most capable French commanders, Turenne and Condé, proved to be more than a match for the Imperial troops and even the famous Spanish infantry. Peace negotiations were begun as early as 1641, but it was not until the brilliant French campaign of 1648 that the Emperor was finally convinced that further warfare was useless, and hostilities were ended by the Treaty of Westphalia. The war with Spain, however, dragged on for another eleven years and was concluded only by the Treaty of the Pyrenees in 1659. M. K.

**THISBE.** *See* PYRAMUS.

**THISTLE** [thɪ′səl], an herbaceous plant of the family Compositae having spiny or prickly foliage. This large genus, *Cirsium,* is made up of the true thistles, which are stout, erect herbs bearing large, showy, flower heads of purple, white, or yellowish tubular flowers. They vary in size between 1 ft. and about 8 ft. The spiny leaves are deeply lobed or cut. Out of the 200 species native to the North Temperate

SWAMP THISTLE, CIRSIUM MUTICUM

Zone, some 70 are found in North America. In the Pacific states, representative species are the Sierra thistle, *C. californicum;* the western thistle, *C. occidentale;* the desert thistle, *C. mohavense;* and the Indian thistle, *C. edule.* On the eastern half of the continent are found the swamp thistle, *C. muticum;* the pasture thistle, *C. odoratum;* the field thistle, *C. discolor;* and the roadside thistle, *C. altissimum.* The Canada thistle, *C. arvense,* which was introduced from Europe, has become a pestiferous weed. In addition to the true thistles, there are many other prickly leaved plants

which are commonly known as thistles. Among them are the blessed thistle, *Cnicus benedictus;* the Scottish thistle, *Onopordon acanthium;* the milk thistle, *Silybum marianum;* the star thistles, *Centaurea;* and the globe thistles, *Echinops.*
J. C. Wis.

**THOMAS, ST.** (Syriac, "twin"), called also Didymus (Greek, "twin"), one of the twelve Apostles. The Gospel of John portrays his enthusiastic devotion to his Master: "Let us go also and die with him" (xi: 16); his slowness to grasp the true personality of Christ: "Lord, we know not whither thou goest" (xiv: 5); and his initial incredulity of the Resurrection: "Except I shall see in His hands the print of the nails and put my hand into His side, I will not believe" (xx: 25). When the risen Christ appeared in the Cenacle again, Thomas confessed His divinity: "My Lord and my God" (xx:28). Tradition maintains that St. Thomas journeyed to India and founded seven churches at Malabar. After his martyrdom near Madras, his body was supposedly buried at Mylapore. Members of the ancient Christian churches of southern India are called "Christians of Saint Thomas." His feast is December 21. W. C.

**THOMAS, EARL OF LANCASTER.** *See* LANCASTER.

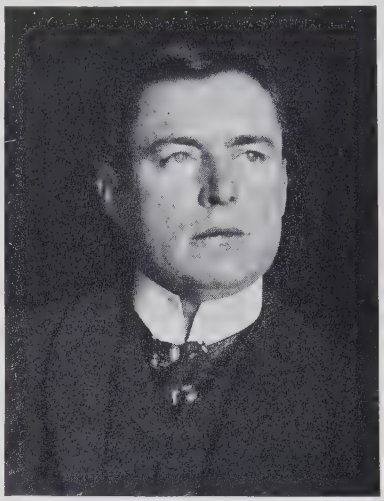
**THOMAS, ANDRÉ ANTOINE** [tɔ′mɑ′] (1857-1936), French philologist and linguist, was born at Saint-Yrieix-La-Montagne (Creuse) on Nov. 29, 1857. He studied at the École des Chartes from 1875 to 1878, and then for three years at the École Française in Rome; from 1881 to 1889 he taught Provençal language and literature at Toulouse, and from 1889 onward he was in Paris as a professor of Romance philology and French medieval literature. In 1904 he became a member of the Académie des Inscriptions et Belles Lettres, a position that he held until his death in 1936.

Thomas was an extremely prolific and sound scholar. Among his most important works in the field of literature, history, and textual criticism may be mentioned *Les États provinciaux de la France centrale sous Charles VII* (1879-1880); *Nouvelles recherches sur l'entrée d' Espagne* (1882); *Francesco da Barberino et la littérature française en Italie au moyen âge* (1883); *Documents historiques bas-latins, provençaux et français* (with Leroux and Molinier, 1883-1885); and *Poésies complètes de Bertrand de Born* (1888).

In the field of linguistics Thomas represents the most rigid Neogrammatical tradition, stressing close adherence to "phonetic laws" and giving phonetics priority over meaning. His chief contributions to linguistics are collected in his *Essais de philologie française* (1897), *Mélanges d'étymologie française* (1902), and *Nouveaux essais d'étymologie française* (1904). With Arsène Darmesteter and Adolphe Hatzfeld, Thomas published the excellent *Dictionnaire général de la langue française* (1889-1900), which continues to be a standard work. G. B.

**THOMAS, AUGUSTUS** (1857-1934), American playwright, was born Jan. 8, 1857, in St. Louis, Mo. Leaving the St. Louis public schools at the age of fourteen, he worked for several years in a railroad office and later as a newspaperman in his native town and in Kansas City. The theatrical activities, both amateur and professional, in which he engaged at this time encouraged him to become a playwright, but *Alone* (1875), his first full-length effort, was not a success. In 1888, as Julia Marlowe's manager, he went to New York, and that city became his permanent home. Thomas' first notably successful play, *Alabama* (1891), gave him a pattern for several other plays of local color, including *In Mizzoura* (1893) and *Arizona* (1899). Some light comedies, among them *Mrs. Leffingwell's Boots* (1905), were followed by his most substantial dramas, *The Witching Hour* (1907), dealing with thought-reading and hypnotism; *As a Man Thinks* (1911), which discussed the double standard of morals; and *The Copperhead* (1918), the story of a Northern spy.

Before his death on Aug. 12, 1934, Thomas had written over sixty plays, long and short. A traditionalist rather than



AUGUSTUS THOMAS

CULVER SERVICE

an experimenter, Thomas was concerned in his plays with theatrical, even melodramatic, situations more than with ideas, but he had a gift for stage effectiveness, and for years he was one of America's most highly regarded dramatists.
O. S. C.

**THOMAS, CHARLES LOUIS AMBROISE** [tɔ′mɑ′] (1811-1896), French composer, was born Aug. 5, 1811, in Metz. After winning the Grand Prix de Rome in 1832, he produced several successful works at the Opéra Comique, but when he tried his hand at serious opera he found that competition with more experienced composers of his time was too great and returned to the Opéra Comique. Here he composed *Psyché* (1857), *Le Carnaval de Venise* (1857), *Mignon* (1866), and *Hamlet* (1868), but in 1871 he was appointed director of the Paris Conservatory, and this virtually ended his career as a composer. Thomas died in Paris, Feb. 12, 1896, and of his works only the tuneful and charming *Mignon* now holds a firm place in the standard repertoire.
D. L. E.

**THOMAS, CHRISTIAN FRIEDRICH THEODORE** (1835-1905), German-American orchestral conductor, was born in Esens, Hannover, Germany, Oct. 11, 1835. Thomas, who came to the United States at the age of ten, was an important musical pioneer in this country during the last half of the nineteenth century, and his pioneering tours in the East and Middle West after 1869 brought good music to many who never before had heard a symphony orchestra. In 1891 he founded the Theodore Thomas Orchestra of Chicago, which, after his death in that city, Jan. 4, 1905, became known as the Chicago Symphony Orchestra. E. L. F.

**THOMAS, DYLAN** (1914-1953), British poet, was born in October 1914 in Carmarthenshire, Wales. He attended Swansea Grammar School and began his career as a writer at an early age. The prominent poets of the 1930's, W. H. Auden and Stephen Spender, had been preoccupied with society; Thomas, ignoring Marx, became preoccupied

with the nature of man, especially the unconscious mind. The poems of *18 Poems* (1934) are Freudian dreams. Their manifest level is a surrealistic confusion of contradictory images, but the latent level, when subjected to Freudian analysis, is simple. Thomas' theme is the cycle of birth and death, and his poetry depends upon the interaction between the rich surface and the latent theme. His first volume was followed by similar collections: *Twenty-Five Poems* (1936), *The Map of Love* (1939), and *Deaths and Entrances* (1946). Some of the less introspective poems of *Deaths and Entrances* concern religion, air raids, and the poet's youth. Thomas also published some surrealistic short stories in *The Map of Love*. His *Portrait of the Artist as a Young Dog* (1940) consists of autobiographical sketches. After World War II, Thomas became a commentator on poetry for the British Broadcasting Company. In America the following of his works have appeared: *The World I Breathe* (1939), *New Poems* (1942), *Selected Writings* (1946), *In Country Sleep* (1952), *Collected Poems* (1953), and *Under Milk Wood* (1954). He died in New York City on Nov. 9, 1953.

W. Y. T.

**THOMAS, GEORGE HENRY** (1816-1870), Union soldier, was born on July 31, 1816, in Southampton Co., Va. He graduated from West Point in 1840 and fought in the Mexican War. Although of Southern birth, Thomas remained in the Federal Army when the Civil War broke out. He assumed command of a Union division late in 1861 and defeated a Confederate force at Mill Springs in southern Kentucky on Jan. 19, 1862, the first decisive Federal victory in the west. He served, successively, under Halleck, Buell, and Rosecrans in the campaigns of 1862 and 1863 which led, eventually, to the vital battles of Chickamauga and Chattanooga. At Chickamauga, in September 1863, Thomas' defense of the center of the broken Union line in the face of the furious Confederate attack earned him the sobriquet "Rock of Chickamauga," and helped the Union forces to effect an orderly withdrawal to Chattanooga. There, in November, with General U. S. Grant in command of all Union forces, Thomas directed the successful assault on Missionary Ridge which routed the Confederates and forced them to retreat into Georgia. In 1864, after Sherman had captured Atlanta and had begun his march to the sea, Thomas successfully protected the Union communication lines by intercepting and defeating Confederate troops under Hood at Nashville, December 15 to 16, in one of the most one-sided battles of the war. Thomas headed the military department of Tennessee after the war and in 1869 was given command of the Division of the Pacific. He died in San Francisco, Calif., May 28, 1870.

T. R. H.

**THOMAS, NORMAN MATTOON** (1884- ), six times Socialist Party candidate for president of the United States, was born in Marion, Ohio, on Nov. 20, 1884, the son of a Presbyterian minister. He was graduated from Princeton University in 1905, and from Union Theological Seminary in 1911. In 1931 he resigned from the ministry. Thomas opposed America's entrance into World War I. After the outbreak of the war, he joined the Socialist Party and became founder and editor of *World Tomorrow* (1918-1921) and secretary of the Fellowship of Reconciliation. In 1921 he served as associate editor of *The Nation,* and in 1922 he was appointed co-executive director with Harry W. Laidler of the League for Industrial Democracy. Thomas was nominated for governor of New York on the Socialist ticket in 1924 and for president in 1928, 1932, 1936, 1940, 1944, and 1948. He opposed America's drift toward World War II, but following Pearl Harbor he supported the war. He lost the leadership of the Socialist Party at its convention in June 1950. His writings, which encourage the need for democratic socialism while voicing opposition to Russian Communism and totalitarianism, include *America's Way Out* (1930), *As I See It* (with Paul Blanshard) (1932), *Human Exploitation* (1934), *Socialism on the Defensive* (1938), *We Have a Future* (1941), *What is Our Destiny?* (1944), *Appeal to the Nations* (1947), *A Socialist's Faith* (1951), and *The Test of Freedom* (1954).

H. W. L.

**THOMAS, SETH** (1785-1859), American clock manufacturer, was born in Wolcott, Conn., Aug. 19, 1785. He was apprenticed early to a joiner, learned cabinet making, and finally, in 1807, entered the clock business when he began

SETH THOMAS

FROM AN ENGRAVING BY J. A. J. WILCOX

CULVER SERVICE

to work for Eli Terry in Greystone, Conn. In 1810 Thomas and Silas Hoadley formed a partnership to make tall wooden-movement clocks. Thomas sold out his interest to Hoadley in 1812 and moved to Plymouth Hollow, Conn. There he founded what became the Seth Thomas Clock Company and began to produce wooden-movement clocks by mass-production methods. Thomas was not an inventor nor an innovator; his success was due rather to a shrewd business acumen. After Eli Terry had secured a patent in 1814 for his shelf clock, Thomas paid Terry $1,000 for the right to use the patent for his own production. Thereafter Thomas produced many kinds of shelf clocks, changing designs as styles changed. All were powered with wooden movements until 1838, when Chauncey Jerome produced a brass movement which Thomas adopted. By 1850 he was making spring-driven clocks. In 1853, with a capital of $75,000, he organized the Seth Thomas Clock Company, which, after his death, was carried on by his son, Seth Thomas. Thomas' grandson and great-grandson, both also named Seth Thomas, later managed the company. Thomas died in Plymouth Hollow (now Thomaston), Conn., Jan 29, 1859.

B. P.

**THOMAS, SIDNEY GILCHRIST** (1850-1885), British metallurgist, was born in London in 1850. Educated at Dulwich College, he was expected to study medicine, but his father's death forced him to leave college. He entered the civil service, devoting his spare time to the study of metallurgy. He qualified for entrance to the School of Mines, but was financially unable to undertake the three-year program. During his studies he conceived the idea of using a strong

base to eliminate the phosphorus which gave serious trouble in the Bessemer steelmaking process. Building a miniature Bessemer converter, he experimented with furnace linings, but became convinced that large-scale operation was necessary. With the co-operation of P. C. Gilchrist he succeeded in dephosphorizing steel in the Bessemer process in 1875 and in 1878 prepared a paper with Gilchrist on his work. It took several years of tireless effort and discouraging failures to make the process commercially successful. Thomas was broken in health when the method had just begun to show the results that have made the Thomas-Gilchrist process the basic open-hearth method of steel production. He died at Paris on Feb. 1, 1885. R. S. Wi.

**THOMAS A KEMPIS** [ə kɛ′mpɪs] (c. 1380-1471), German priest, educator, and reputed author of *De Imitatione Christi (Of the Imitation of Christ),* was born Thomas Hamerken or Hämmerlein. The name by which he is known is a Latin school title, derived from the town of Kempen, near Düsseldorf, where he was born about 1380. He was educated at Deventer in Holland at a school of the Brothers of the Common Life, an association newly founded by Gerhard Groote. At the age of twenty he entered the neighboring monastery of Zolle, which had been established under the inspiration of Groote to act as the spiritual center of his association. Here, except for a few short intervals, he resided until his death at the age of ninety-two, employing his talents, in hours not given to prayer, in copying manuscripts, teaching, administration, and literary composition.

Whether Thomas a Kempis composed the *Imitation of Christ* or was merely the copyist responsible for the earliest manuscript containing the complete text is the subject of a long-standing controversy. From about 1600 until 1900 authorship was sometimes attributed to Jean Charlier de Gerson, a famous theologian contemporary with Thomas. This theory had scarcely been abandoned when a new claimant was put forward in the person of his contemporary Gerhard Groote. Whoever the author of the treatise may have been, he seized on the essential spirit of Christianity as an inner life, and expressed it with a nobility and charm to which few men can remain insensible. The book has been the vade mecum of most of the saints of the modern era. It has won admiration from persons of widely divergent religious views, including Samuel Johnson, John Woolman, George Eliot, and Matthew Arnold. Some have recognized in it an answer to a fundamental need of the human heart, that of finding inward peace through self-knowledge, self-discipline, and generous love. J. A. Sl.

**THOMASTON,** a city in west central Georgia, the county seat of Upson Co., located about 60 mi. south of Atlanta. It is served by the Central of Georgia Railway. In the fertile rolling countryside general farming and cattle raising are carried on, and the chief agricultural product is peaches. Local manufactures include a variety of textiles and tire fabrics. Thomaston, settled about 1825, was incorporated in 1872. The city government is administered by a mayor and council. Pop. 1950, 6,580.

**THOMASVILLE,** a city in southern Georgia, the county seat of Thomas Co., located 200 mi. south of Atlanta. Thomasville was founded in 1823 and incorporated three years later. It has the council-manager form of government. It is a popular winter resort, one of the first noted vacation spots in the South, and the city's rose gardens attract many visitors. Thomasville is the seat of the Vashti Industrial School for girls and of a veterans' hospital. The Atlantic Coast Line Railroad provides transportation. The county's largest income is derived from farming, with tobacco, peanuts, and truck crops the chief produce. Lumbering is also important in this yellow-pine district. Thomasville's chief industrial plants manufacture cotton thread, wearing apparel, food products, and crates and baskets. Pop. 1950, 14,424.

**THOMASVILLE,** a city in Davidson Co., in west central North Carolina, in the fertile Piedmont section of the state, located 18 mi. southeast of Winston-Salem. Founded in 1852 and incorporated in 1854, the city has the council-manager form of government. There is a Baptist orphanage in the city, which has transportation facilities provided by the Southern and the High Point, Thomasville & Denton railroads. An industrial city, Thomasville has large cotton and hosiery mills and furniture factories. Pop. 1950, 11,154.

**THOMPSON.** *See* INDIAN TRIBES, NORTH AMERICAN (*Plateau*).

**THOMPSON, ERNEST SETON.** *See* SETON, ERNEST THOMPSON.

**THOMPSON, FRANCIS** (1859-1907), English poet, was born at Preston, Lancashire, on Dec. 16, 1859, the son of Charles and Mary Thompson, both converts to Roman Catholicism. In 1864 the family moved to Ashton-under-Lyne, near Manchester, and this was Thompson's home until 1885. He recalled his childhood as painful, but he seems to have had hours of contented leisure, during which he read Scott, Coleridge, and Shakespeare. In 1870 he entered

*FRANCIS THOMPSON*

COURTESY OF THE NEW YORK PUBLIC LIBRARY

Ushaw Seminary, Durham, where his shyness and frail body brought upon him the ridicule of his schoolmates; in 1874 he transferred to Ushaw College to study for the priesthood, but when he graduated in July 1877 the president of the school wrote that Thompson's "nervous timidity" unfitted him for that calling. Despite his increasing interest in poetry, he acceded to his father's urging to study medicine at Owens College, Manchester. A severe fever in 1879 was possibly the occasion of his first taking laudanum, and after six years of failure at Owens he fled to London in November 1885, where he lived for two years in great poverty.

From a life of match selling, cab calling, and laudanum drinking he was rescued by Wilfrid Meynell, editor of *Merry England,* who was impressed with poems sent him for publication and who, after long delay, sought him out in the

spring of 1888. Meynell helped him to regain partial health and published in *Merry England* his essays and poems, notably *The Hound of Heaven* (1890). Although Thompson still suffered from occasional depression, he was moderately happy during the rest of his life under the affectionate care of the Meynells and earned a modest living by journalism. In 1893 he published his *Poems,* on which his fame chiefly rests; this volume was followed by *Sister Songs* (1895), *New Poems* (1897), and a prose work, *Health and Holiness* (1905). His famous essay on Shelley (1889) was posthumously published in 1908. Thompson died of tuberculosis in London on Nov. 13, 1907.

Thompson's poetry, uncritically acclaimed and condemned when it appeared, "seethes with imagery," as its author said, and is an odd combination of Shelley and Crashaw, with touches of Coleridge, De Quincey, and, in late poems, Coventry Patmore, his friend. What it lacks in form and restraint is compensated for by its "full stream." Though Thompson could write simply and tenderly, his verse is most original when it is most turbulent, fantastic, and involuted. He has been called a mystic, a term he shunned; but he might be called, simply and properly, a religious poet, of narrow but splendid talent. L. A. C.

**THOMPSON, JOHN TALIAFERRO** (1860-1940), American soldier and inventor, was born in Newport, Ky., Dec. 31, 1860. He graduated from West Point in 1882 and after attending army schools entered the Ordnance Department in 1890. He retired from active service in 1914 as a colonel of ordnance. When the United States entered World War I, Thompson was recalled to active duty as chief of the Small Arms Division of the Ordnance Department. He was promoted to brigadier general in 1918 but at the end of the war retired once again and entered private business.

During his years of active service Thompson invented a number of semiautomatic rifles for both the standard .30-cal. cartridge and the .276-cal. Pederson cartridge, but none of these rifles proved successful. In 1920, however, the Thompson machine gun, or "Tommy gun," was developed and put on the market. This was a .45-cal. submachine gun, weighing about 10 lb., with full automatic or semiautomatic fire, and was among the first of its type to be made in the United States. The first military use of the gun was by United States Marines in Nicaragua in 1925. The gun was used in South America and China in the 1930's and a modification was adopted for the use of the United States and its allies during World War II.

In his last years Thompson devoted much time to the development and sale of his submachine gun. He died at Great Neck, Long Island, N. Y., June 21, 1940. R. W. Cr.

**THOMSON, ELIHU** (1853-1937), American inventor, was born in Manchester, England, on Mar. 29, 1853. His parents brought him to the United States when he was five years old, and after his education he taught chemistry and mechanics in a Philadelphia high school. In 1880 he went to work as an electrician in New Britain, Conn., and there began a series of important researches into the electric arc. With Edwin James Houston, an electrical engineer, Thomson in 1881 developed a practical system of arc lighting that was used extensively. In 1883 he and his collaborator organized the Thomson-Houston Electric Company in Lynn, Mass. This company was merged in 1892 with the Edison Company to form the General Electric Company, the world's largest manufacturer of electrical equipment. Thomson remained in charge of the laboratories at Lynn and was responsible for many notable advances in electrical engineering. In 1886 he invented the incandescent method of electric welding. Thomson also contributed to the successful development of the alternating-current motor. In 1890 he constructed the first high-frequency dynamo and soon thereafter developed the first high-frequency transformer. During his lifetime Thomson obtained patents on more than seven hundred inventions, including the centrifugal cream separator, the watt-hour meter, and important developments in radiology. He died in Swampscott, Mass., on Mar. 13, 1937. G. Q.

**THOMSON, JAMES** (1700-1748), English poet and dramatist, was born at Ednam in Roxburghshire, Scotland, probably on September 7, 1700, and died at Richmond in England, August 27, 1748. He attended Grammar School at Jedburgh, and later entered Edinburgh University in 1715 where, from 1719 to 1725, he studied divinity in preparation for the Presbyterian ministry. Finding the study of theology distasteful, he went to London in 1725, where he became the friend of Gay, Arbuthnot, Pope, and other men of letters. His small earnings as a tutor and the sinecures and pensions he enjoyed later through the patronage of influential persons, including the Prince of Wales, assured him leisure to devote to his writings. A juvenile poem, *Of a Country Life,* had early revealed Thomson's sensitiveness to rural scenery and his sincere love of nature. His first important nature poem was *Winter* (1726), the unexpected success of which in an age primarily concerned with poetry urban in quality and theme and done in polished heroic couplets led to the publication of *Summer* (1727), *Spring* (1728), and *The Seasons,* including *Autumn* and a *Hymn on the Seasons* in 1730. A greatly expanded and rewritten edition of *The Seasons* appeared in 1744. In addition to *The Seasons* and to certain juvenile and miscellaneous poems that merit no mention, Thomson wrote *A Poem Sacred to the Memory of Sir Isaac Newton* (1727), an understanding and genuine tribute to the great scientist who had died that year; *Liberty* (Parts I, II, III, 1725; IV, V, 1736), a blank-verse poem, stilted in form and prolix in praise of the Goddess of Liberty, yet showing an early poetic treatment and appreciation of architecture and sculpture; and *The Castle of Indolence* (1748), an allegory done in Spenserian stanzas that imitate aptly the melodic manner and sensuous imagery of Edmund Spenser. Thomson's dramatic works, *Sophonisba* (1730), *Agamemnon* (1738), *Edward and Eleonora* (1739), *Alfred: A Masque* (with David Mallet or Malloch, 1740), and *Coriolanus* (posthumously produced in 1749), are memorable examples of the low ebb of dramatic taste and achievement during the period. They purport to be tragedies, and most of them have contemporary political implications. *Alfred* contained the patriotic lyric *Rule, Britannia.*

*The Seasons* is Thomson's major work and the most important nature poem of the pre-Romantic period. Its Latinized diction, the Miltonic quality of the blank verse, the idyllic scenes portrayed, the rhapsodic style in many passages, the excursive flights of fancy to polar and torrid regions, the sentiments concerning benevolence and humanitarian themes, the scientific interpolations, and the philosophic bias reveal Thomson as an eclectic poet who drew inspiration from many sources. Though not a Romantic poet himself, Thomson's sensitive and enthusiastic treatment of nature and the comman man, his often precise descriptive phrasing, and his imaginative treatment of subject, coupled with a sincere effort to achieve emotional effect, show him to be the most significant harbinger of the Romantic Movement in English literature. H. Dr.

**THOMSON, JAMES** (1834-1882), British poet and journalist, was born in Port Glasgow, Scotland, Nov. 23, 1834. He was educated for a teaching position and in 1851 became assistant army schoolmaster at Ballincollig in southwestern Ireland. There he formed a friendship with Charles Bradlaugh, the social reformer, and fell in love with Matilda Weller, whose death in 1853 caused him severe grief. He taught school at several posts between 1854 and 1862, observed much outdoor life, and read widely before he was discharged from the army on slight grounds. Bradlaugh then helped him to become a solicitor's clerk and a journalist. Thomson's contributions to the *National Reformer* included *To Our Ladies of Death* (1861) and *The City of Dreadful Night* (1874), the latter praised by George Eliot and George Meredith. In 1869 his *Sunday up the River,* which contained "Give a man a horse he can ride," appeared in *Fraser's Magazine.* From 1866 until his death he occupied single lodgings in London, except for a short trip in 1872 to Colorado, where he represented the stockholders of a mining company, and one in the following year to Spain as war correspondent. After suffering the afflictions of alcoholism, poverty, and depression during the remainder of his life, he died June 3, 1882, in University College Hospital, London.

Thomson adopted the pen name "B. V." (for "Bysshe Vanolis") in honor of Shelley and Novalis. His work, which is at times cheerful, is predominantly somber. Much of his prose and verse was collected posthumously, but *The City of Dreadful Night and Other Poems* was published in 1880 with the aid of Bertram Dobell. Thomson's masterpiece, the title poem of that collection, symbolizes the world as a city empty of life except for a few doleful wretches over whom presides Melancholia, the embodiment of utter pessimism. It is compelling in its imagery, sonorousness, and sustained gloom. W. D. T.

**THOMSON, SIR JOSEPH JOHN** (1856-1940), British physicist, was born near Manchester, England, on Dec. 18, 1856. He was educated at Owens College, Manchester, and Trinity College, Cambridge. Soon after his graduation from the latter he began a lifelong association with Cambridge University, where, as Cavendish Professor, he made important contributions to nuclear physics. A brilliant study of the cathode rays, which Thomson announced in 1897, led to the discovery that the electron is a body smaller than the hydrogen atom and that electrons are to be found in all matter. Thomson also devised a new way of separating different kinds of atoms and molecules, and his researches paved the way for the discovery of various isotopes. For his studies of the conduction of electricity through gases, Thomson was awarded the 1906 Nobel Prize for physics. He became master of Trinity College in 1918, a post he held until his death in Cambridge on Aug. 30, 1940. Thomson's most important writings were *The Application of Dynamics to Physics and Chemistry* (1888), *Elements of the Mathematical Theory of Electricity and Magnetism* (1895), *Rays of Positive Electricity* (1913), *The Electron in Chemistry* (1923), and *Recollections and Reflections* (1937). G. Q.

**THOMSON, VIRGIL** (1896- ), American composer and critic, was born in Kansas City, Mo., Nov. 25, 1896. He was educated at Harvard University and later studied with Nadia Boulanger in Paris, where he lived from 1925 to 1932. He was critic for the New York *Herald Tribune,* 1940-1954. Among Thomson's best-known compositions are the two operas on librettos by Gertrude Stein, *Four Saints in Three Acts* (1934) and *The Mother of Us All* (1947); a ballet, *The Filling Station* (1938); and the incidental music for the documentary films *The Plow That Broke the Plains* (1936), *The River* (1937), and *Louisiana Story* (1948). E. L. F.

**THOMSON, WILLIAM.** *See* KELVIN OF LARGS, BARON (WILLIAM THOMSON).

**THOR** [thɔ'r], in Scandinavian mythology, the god of thunder and son of Odin and Jord. His wife was Sif. His widespread cult is attested by the equally widespread use of his name for the fifth day of the week, Thursday, among the Teutonic peoples. Thor is represented as a man of fabulous strength, red-bearded, and riding in a goat-drawn chariot which caused the thunder by its rolling. He was popular as the benevolent friend and protector of men. Thor's three precious possessions were the girdle of strength, iron gloves, and the magic hammer, Mjollnir, with which he slew the giant demons and which returned to him like a boomerang (the thunderbolt). Thor is identified with Jupiter and with the Anglo-Saxon god Thunor or Thonar. C. W. D.

**THORACIC SURGERY.** *See* SURGERY.

**THORBORG, KERSTIN** [tu'rbɔry] (1906- ), Swedish operatic contralto, was born at Venjan, Dalekarlia, May 19, 1906. She appeared at the Royal Opera, Stockholm; at Covent Garden, London; at the Colon in Buenos Aires; and in Vienna, Salzburg, Berlin, Prague, and Munich. She made her American debut at the Metropolitan Opera House, New York City, Dec. 21, 1936, as Fricka in *Die Walküre.* She remained on the roster of the Metropolitan until 1946. Her Metropolitan roles included Fricka, Erda, and Waltraute in the *Ring* cycle, Ortrud in *Lohengrin,* Magdalena in *Die Meistersinger,* Brangäne in *Tristan und Isolde,* and Venus in *Tannhäuser.* In 1938 she sang Klytemnestra in the Metropolitan's revival of Richard Strauss's *Electra* and Octavian in his *Rosenkavalier.* In Europe she sang the title role in his *Salome.* F. G. P.

**THOREAU, HENRY DAVID** [thɔ'ro] (1817-1862), American essayist and poet, was born July 12, 1817, in Concord, Mass., of mixed Scottish and Huguenot ancestry. After preparing at the Concord Academy, he entered Harvard in 1833 and graduated four years later; at Harvard his participation in college activities was limited, but he read widely in poetry, particularly that of the seventeenth century. After his graduation, he and his brother John conducted a successful private school until the latter's death in 1841. Grief over this loss, the most poignant that Thoreau ever experienced, led him directly to the writing at Walden of his first book, *A Week on the Concord and Merrimack Rivers* (1849). Based upon a journey taken by the brothers in 1839, but drawing heavily upon the voluminous journals which Thoreau began keeping after he left college, the narrative is obscured by discursive, essaylike observations, and as a result, though it is occasionally charming, the book was understandably neglected. At the same time, however, this first effort gives evidence of Thoreau's reading in the Oriental scriptures, which he had begun at Emerson's suggestion at about the time of the journey, and of his growing sympathy with Emerson, Bronson Alcott, and other members of the Concord Transcendental group. It also shows his interest in Alcott's *Conversations,* begun in 1840, and in *The Dial,* launched in the same year; to the latter Thoreau contributed translations, an essay, and several poems, and in addition he assisted in its management. His lectures in Concord and

neighboring towns also reflected his interest in the Transcendentalist movement.

On July 4, 1845, Thoreau entered upon the most significant single experience of his life, his residence at Walden Pond. Fond of nature from childhood, he undertook the experiment with two avowed purposes: to determine to what extent life could be stripped of non-essentials and driven "into a corner," and to accomplish certain private tasks of a literary nature. To this may be added an unacknowledged need for peace from certain personal losses. This episode, although it lasted for only twenty-six months and was interrupted in 1846 by the visit to Maine, bore fruit in Thoreau's most memorable work, *Walden,* or *Life in the Woods* (1854). Treasured by lovers of nature for its detailed and perceptive descriptions of the phenomena of the seasons, of the physical aspects of the region, and of its flora and fauna, this book is also filled with trenchant social criticism and is generally regarded as one of the classics of American literature.

HENRY DAVID THOREAU

COURTESY OF THE NEW YORK PUBLIC LIBRARY

Records of Thoreau's travels within and outside New England are to be found in *Excursions* (1863), *The Maine Woods* (1864), *Cape Cod* (1865), *A Yankee in Canada, with Anti-Slavery and Reform Papers* (1866), and in F. B. Sanborn's *The First and Last Journeys of Thoreau* (1905). An ardent enemy of slavery, Thoreau deplored the Mexican War, opposed the return of fugitive slaves, and defended John Brown; three of his addresses—*Civil Disobedience* (1848), *Slavery in Massachusetts* (1854), and *A Plea for Captain John Brown* (1859)—indicate the strength of his feeling on these subjects. To active association with his father in pencil-making he joined a knowledge of surveying and a New England readiness at handiwork. His capacity for friendship was considerable, some of his most intimate friends being Emerson and Mrs. Emerson, Nathaniel Hawthorne, and especially Ellery Channing. His death, which occurred in Concord on May 6, 1862, caused grief to many, not only among the Transcendental circle, but among neighbors and children in particular, who found him always ready for a ramble in the woods. He was buried in Sleepy Hollow Cemetery, Concord. B. V. C.

**THORGILSSON, ARI (FRÓDI) THE LEARNED** [thɒ′rgɪlsɒn] (1067-1148), Icelandic historian, was born in West Iceland in 1067 and lived in Haukadalr, a seat of learning in southern Iceland. Ari is the father of Icelandic saga writing, which to him meant historiography. Only an abridgment of Ari's *Íslendingabók* ("Book of Icelanders") (c. 1122-1133) survives; the complete work contained genealogies and kings' lives omitted in the abridgment. Influenced by eleventh-century chronicles, Ari was a painstaking chronologist, but he could also tell a good story. Probably he had something to do with the *Landnámabók* ("Book of the Land-taking"), a unique genealogical-geographic work, which enumerates approximately four thousand early settlers of Iceland. S. E.

**THORIUM** [tho′riəm], symbol Th, atomic number 90, at. wt. 232.12, density 11.2, m.p. 1,845° C., b.p. over 3,000° C. Thorium, named for Thor, the Norse god of war, is the second member of the Actinide series in the periodic table which includes elements numbers 89 through 98. Thorium is a transition element having an atom which contains five completed shells of electrons (2, 8, 18, 32, 18), a sixth, incomplete shell of 10, and an outer shell of 2. It is a heavy gray metal, slightly malleable and ductile, magnetic, and radioactive; it burns brilliantly when heated in air, is soluble in concentrated hydrochloric acid and aqua regia, and is not attacked by alkalies. In all its compounds, thorium is quadrivalent; its solutions are colorless. The oxide, $ThO_2$, used as a catalyst and in incandescent gas mantles with cerium dioxide, has been called the most refractory substance known. Thorium nitrate, $Th(NO_3)_4$, a white crystalline salt readily soluble in water, is also of industrial importance. The possibility of producing fission, as in uranium, has greatly increased interest in thorium and its compounds. B. S. H.

**THORNDIKE, EDWARD LEE** (1874-1949), American psychologist, was born at Williamsburg, Mass., on Aug. 31, 1874. He was educated at Wesleyan, Harvard, and Columbia universities. After a year as instructor in education and teaching at Western Reserve University, he went to Teachers College, Columbia University, where he taught until his retirement in 1941.

Thorndike was in no small way responsible for opening the way for education to develop a scientific foundation, starting with his early books, *Educational Psychology* (1903), *Mental and Social Measurements* (1904), and *The Principles of Teaching* (1905). His primary interest in the learning process in children, adults, and even animals was made evident in such later writings as *Animal Intelligence* (1911) and *The Origin and Nature of Man* (1913). His *Psychology of Learning* (1914) is a basic work on the process of learning. During World War I, Thorndike was chairman of the Committee on Classification of Personnel in the United States Army. His methods of psychological measurement employed there set the pattern for personnel placement and vocational and educational guidance, as is shown in the continued wide use of his many tests and scales. *The Measurement of Intelligence* (1926), along with many articles and studies, represents this major area of his interest. In *Adult Learning* (1928) he turned his attention toward the mature individual. *The Fundamentals of Learning* (1932), perhaps his most important published work, is a scholarly review of his own experience on the subject of learning. In *Your City* (1939) he turned to adult learning in community living and criticized many of the so-called good influences in city life. Among his last books are *Human Nature and the Social Order* (1940) and *Man and His Works* (1943). Thorndike died on Aug. 9, 1949, in Montrose, N. Y. A. W. S.

**THORNY DEVIL.** *See* MOLOCH.

**THOROLD** [thɔ′rold], a town in Welland Co., Ontario, Canada, located 7 mi. west of Niagara Falls at the point where the Welland Ship Canal climbs the Niagara Escarpment by means of the great Twin Flight Locks. Thorold was founded by United Empire Loyalists before 1800; it was incorporated as a village in 1850 and as a town in 1874. Many industries have been attracted by the canal and the abundant hydroelectric power of the district. Articles manufactured in Thorold include pulp, paper and paper products, steel products, tools, dies, machinery, abrasives, and firebrick. The town is served by the Canadian National and the Niagara, St. Catharines and Toronto railways. Pop. 1951, 6,397.
D. F. P.

**THORPE, JAMES FRANCIS** (1888-1953), American athlete, was born near Prague in the Indian Territory (now Oklahoma) on Mar. 28, 1888, of mixed Irish, French, and Indian ancestry. He attended the Haskell Institute at Lawrence, Kans., and the Carlisle Indian School at Carlisle, Pa., where in 1907 his athletic abilities attracted the attention of Glenn S. "Pop" Warner, famous athletic coach. Thorpe soon became an outstanding athlete and starred at football in 1908. In 1909 he went south under Carlisle direction to do farm work and in the summers of 1909 and 1910 played professional baseball with various minor league clubs in the south, a common practice with collegians of that day. In 1911 he returned to Carlisle. His feats on the football field that year and the next as he led little Carlisle to victories over the best teams in the country have become part of football legend, and in both 1911 and 1912 he was named to Walter Camp's All-American team.

In the summer of 1912 Thorpe won both the pentathlon and the decathlon in the Olympic Games at Stockholm, the only time such a double victory was ever achieved in the Olympics. He won four of the five pentathlon events, broke all scoring records in the ten-event decathlon, and established himself as the greatest all-around athlete of his day. In January 1913 the Amateur Athletic Union, discovering that Thorpe had played professional baseball, deprived him of his amateur status and forced him to return his Olympic medals and trophies. Thorpe admitted that he had played professionally, but pleaded that he did not realize that such action would bar him from future amateur competition.

Thorpe left Carlisle in 1913 and played major-league baseball with the New York Giants, Cincinnati Reds, and Boston Braves until 1919. He also played professional football and in 1920 became the first president of the American Professional Football Association (later the National Football League). He played with the Canton Bulldogs, the New York Giants, and other clubs before retiring in 1929 at the age of 41. Thereafter, he occasionally appeared with carnivals, on lecture platforms, or in motion pictures. In World War II, when he was past 50, he served with the Merchant Marine. Thorpe died on Mar. 28, 1953, in Lomita, Calif. An Associated Press poll in 1950 named him the greatest football player and the greatest all-around athlete of the twentieth century.
R. W. Cr.

**THORVALDSEN, BERTEL** [tʊ′rvalsən] (1770-1844), Danish sculptor, was born in Copenhagen on Nov. 19, 1770, the son of an Icelandic ship's carpenter and carver who had emigrated to that city. The young Thorvaldsen studied at the Danish Academy of Art from the age of eleven, obtained a traveling scholarship in 1792, and in 1797 went to Rome, where he remained throughout most of the rest of his life.

Although often called phlegmatic and uninspired, Thorvaldsen earned recognition as one of the leading figures of the then thriving neoclassic movement. He emphasized the importance of Greek art as the basis of Classic style and prided himself on his authentic imitation of it, but his work most nearly resembles the general neoclassic product, and its particular Hellenism is evident mainly only in the predominance of Greek subjects and the adaptation of Greek originals, as in his *Jason,* which he based on the *Apollo Belvedere.* In his equestrian statue of the Polish patriot, Prince Józef Antoni Poniatowski, he closely followed the late Roman statue of Marcus Aurelius.

Thorvaldsen was commissioned by Count Ludwig of Bavaria to restore the pediment sculptures of the early Greek temple at Aegina; he is also known for the *Lion of Lucerne,* carved in living rock. Interested in style rather than craft, Thorvaldsen developed the practice of modeling his compositions and having them carved by studio assistants. He returned to Denmark in 1838, with the completed colossal statues of Christ and the twelve Apostles for which he had been commissioned; he died in Copenhagen Mar. 24, 1844.

**THOTH** [tho′th; to′t], the scribe of the gods in the religion of ancient Egypt. He was also noted as measurer of time, inventor of numbers, and mediator between Horus and Set, from which arose his reputation as a god of wisdom. Though portrayed in the form of a baboon, he received honors from the Pharaohs. In the judgment hall of Osiris, Thoth recorded the results when hearts were weighed.

Originally a moon god, in the Osiris myth Thoth represented Horus and his allies, and, above all, Set and his partisans. Thoth was usually drawn with the head of an ibis or as a cynocephalus. The Greeks identified him with Hermes (Mercury). Above all other Egyptian deities, Thoth created through his words, and, in the Mystery Play of the Succession, typical Egyptian words of deception are put into his mouth. In Hermopolis, center of his worship, he appeared at times to take personal initiative in creative acts; at other times he was merely an instrument of the creator.

As divine scribe, Thoth figured in the coronation ceremonies. According to inscriptions, during her crowning, Hatshepsut (c. 1495-1480 B.C.) was addressed by Thoth in these words: "I establish for thee then thy crown." A prayer to Thoth, dating from the thirteenth century B.C., opens with a touch of simple piety: "Thoth, thou sweet fountain for one who thirsteth in the desert." Thus, Thoth of Hermopolis, who became private scribe to the supreme deity, Ra, acquired a place in the cosmic scheme.

**THOUSAND AND ONE NIGHTS, ONE.** *See* ARABIAN NIGHTS, THE.

**THOUSAND ISLANDS,** a group of about 1,700 small islands almost blocking the St. Lawrence River where it leaves Lake Ontario. Some of the islands belong to the United States (New York State), and some to Canada (Province of Ontario). Geologically, they are part of a wide strip of granite rock, a prolongation of the Canadian Shield, which links the "Frontenac uplift" of Canada to the Adirondack Mountains in the United States. The largest islands are Wolfe, 18 mi. long, and Howe, both in Ontario; and Grindstone and Wellesley, in New York. The Thousand Islands International Bridge, opened in 1938, connects Collins Landing in New York with Ivy Lea in Ontario. The islands are a popular resort.
G. T.

**THOUSAND-LEGGED WORM,** the common name given to the millepedes and sometimes erroneously to the centipedes. *See also* MILLEPEDE.
W. I.

**THRACE** [thre's], the ancient name of a Balkan area bounded on the north by the Danube River, on the east by the Black Sea, on the south by the Aegean Sea, and on the west by the Strimón River. This wild and rugged territory was inhabited by fierce and warlike tribes, the Thracians, who resisted conquest by the civilized countries of the Classical period. The rough, wooded topography made military operations difficult, and, while the Thracians lacked an organized government, they withstood inroads by the Persians, Greeks, Macedonians, and Romans. It was not until A.D. 46 that Thrace became a Roman province, although it had been a client kingdom in the reign of Augustus. The primitive culture was reflected by the historian Herodotus, who recorded the presence of lake dwellers in the fifth century B.C., one thousand years after the lake cultures of Switzerland and northern Italy had disappeared. The river settlements of Adrianople (now Edirne) and Philippopolis (now Plovdiv) were the only large towns during the Roman period. T. B. J.

**THRACIAN** [thre'shən], an apparently Indo-European language of the satem type formerly spoken in the eastern part of the Balkan Peninsula, in ancient Moesia (now Bulgaria), and Dacia (now Romania). Its Indo-European nature is indicated by words like Σεμέλη (the Greek goddess of Thracian origin), which is comparable to Russian *zjemljá,* Latin *humus,* and Greek *χθών, χαμαί*; Βετ-έσπιος, or Οὐτ-άσπιος, the name of the Thracian equestrian hero, comparable to Latin *equos* and Vedic *áśva-s;* Ρῆσος, the name of a Thracian king, perhaps to be compared to Latin *rex, regis and* Vedic *rájā* (king); and δίζος, δίζα ("fortress"), comparable to Greek τεῖχος, Latin *fingo,* German *teig,* English *dough,* and others.

Thracian is known through personal names, the most typical being those ending in *-centus, -poris* and *-tralis,* and place names, many of which end in -διζος or -διζα, *-deua* or *-daua,* and *-bria.* There is only one Thracian inscription in Greek characters, perhaps a hexameter, found on a ring at the Bulgarian village of Ezerovo near Plovdiv (Philippopolis); but its interpretation is very uncertain. Thracian is very closely connected with Phrygian and Armenian on one side and with the Slavic languages on the other; it is perhaps the direct ancestor of Albanian, which is also a satem language. The pre-Roman substratum of Romanian was also probably Thracian, for Dacian was very probably a Thracian dialect. G. B.

**THRASHER,** any one of a number of species of medium-sized (9-12 in.) American songbirds combined in the genus *Toxostoma* of the family Mimidae. They are allied to the mockingbirds and catbirds. They range from southern Canada to southern Mexico. Thrashers are characterized by a long, slender curved bill, short wings, and a long tail; their plumage is mainly shades of brown or gray, and some species have the under parts conspicuously streaked with black. They inhabit brushy country and are usually somewhat retiring birds, although they may mount to an exposed perch to sing. Their notes are melodious and scarcely inferior to those of the mockingbirds. The brown thrasher, *T. rufum,* of eastern North America is foxy red-brown above, white below, with heavy black streaks; it is common almost everywhere west to the Rocky Mountains. In the western states many other thrashers occur, of which some are difficult to distinguish. Among the best known are the California thrasher, *T. redivivum,* brown above and buff beneath; the curve-billed thrasher, *T. curvirostre,* brownish-gray above and white with brownish-gray spots beneath; and the crissal thrasher, *T. crissalis,* similar to the last, but lacking the spots and having the under tail-coverts chestnut. H. G. De.

**THREADWORMS,** or whipworms, true nematode round worms of the phylum Nemathelminthes. They are widely distributed in mammals in the warm moist regions of the world. The human species, *Trichocephalus* (*Trichuris*) *trichiura,* is found in the cecum, appendix, and colon regions of the intestine; it may be responsible for various gastrointestinal disturbances. Infection is established by ingesting eggs containing the infective larvae. The anterior three-fifths of this worm is drawn out into a whiplike process. The females may be 1½ to 2 in. long; the male is somewhat smaller, 1 to 1¾ in. R. F. N.

**THREE FATES.** *See* FATES.

**THREE HOURS' AGONY.** *See* GOOD FRIDAY.

**THREE-MILE LIMIT,** the jurisdiction of a coastal state extending to the open sea a distance of three miles measured from low tide. In international law it is often called the marginal sea. The three-mile limit became generally recognized after the publication of Cornelis van Bynkershoek's *De dominio maris* in 1702, in which he established the principle that the territorial jurisdiction ends where the effective force of arms ends. The range of cannon of that day seems to have set a marine league, or three nautical miles, as the limit. A wider limit of jurisdiction is desirable and is sometimes maintained by courtesy or by treaty agreement. In 1930 a Conference for the Codification of International Law was held at The Hague, but no agreement was reached on a general convention on the territorial sea. It is generally agreed that the three-mile limit includes the air above the waters as well as the bed of the sea and its subsoil. H. B. C.

**THREE MUSKETEERS, THE.** *See* TROIS MOUSQUETAIRES, LES.

**THREE RIVERS,** a city in St. Joseph Co., in southwestern Michigan, situated at the confluence of the St. Joseph, Portage, and Rocky rivers, 23 mi. south of Kalamazoo. It was founded in 1830 and incorporated in 1895. Three Rivers is governed by a council and city manager. In the seventeenth century it was the site of a Jesuit mission. The community is served by the Michigan Central Railroad of the New York Central System. It is chiefly a manufacturing city, and its products include steam pumps, windmills, stokers, electric saws, paper containers, boxboard, and fur and woolen garments. Farms of the area are engaged in dairying and stock raising. Pop. 1950, 6,785.

**THREE SISTERS, THE** (*Tri Syestrai*), a three-act play by the Russian writer Anton Chekhov (1860-1904), first produced in 1901 by the Moscow Art Theatre.

Its main characters, Olga, Marya, and Irina, the sisters Prozorov, live with their brother, Andrei, in a provincial Russian town, whence they have come from Moscow to live with their widowed father, a general of the Russian army. Olga, the eldest, is a school teacher; Marya is the wife of a school teacher; and Irina, the youngest, feels she must work to make her life worth while.

Life in the town is drab and monotonous, the people backward and crude. Memories of their beloved Moscow, where all of them were born, haunt the sisters, and after their father's death the desire to go back to Moscow becomes

overwhelming. "To Moscow!" "To Moscow!" is the cry heard throughout the play. But unfortunate events prevent the fulfillment of their desire.

In Chekhov's plays there is almost no action, but there is a powerful evocation of mood. Thus, in *The Three Sisters* is found a profound sense of the sadness and tragedy of existence. Here are portrayed the Russian intelligentsia of the time—people without will and without firm ground under their feet, without a clearly defined purpose in life.

N. M. S.

**THREONINE.** *See* PROTEINS.

**THRESHER SHARK,** *Alopias vulpinus,* or fox shark, a large fish of the family Alopiidae, easily recognized by the long curved tail which exceeds the length of the head and body together. It is widely found in most temperate and tropical seas and is common in the Atlantic and Mediterranean. A fast-swimming giant that attains a weight of 1,000 lb. and a length of 20 ft., it sometimes uses its tail to obtain fishes for food. One or more thresher sharks will swim around a school of fishes, lashing the prey into a mass where they can easily be captured. They also have been observed throwing fish in or toward the mouth by a sweep of the tail. The thresher shark is a weak-toothed species harmless to man, and it is of little economic value. E. C. R.

**THRIFT,** a name often given the common sea pink, *Armeria maritima,* a low, tufted evergreen perennial of cool northern regions, cultivated in many varieties for its showy flowers. It grows to about 1 ft. in height. J. C. Wis.

**THRIPS,** the name given to insects of the order Thysanoptera. They are almost all minute creatures, of very slender build, less than 1/15 in. in length. The wings are very peculiar, being long and narrow with close-set hairs on both borders, which serve to increase the lifting area. Most of the thrips feed upon plant tissues, but some kinds are predaceous upon other thrips and small insects in general. A few have become so closely associated with the pollination of plants that they are almost essential in the production of fruit, but because of their small size and secretive habits, little is known about them. Parthenogenesis is common in the order; in the greenhouse thrips, *Heliothrips haemorrhoidalis,* and the pear thrips, *Taeniothrips inconsequens,* males are extremely rare. One of the most serious pests in the order, *Thrips tabaci,* the onion or tobacco thrip, causes enormous damage to many crops but is also important as a pollinator of various other plants. It is a general feeder. The very small eggs are laid on or in plant tissues and the young resemble the adults except for the fact that they are wingless. The largest known thrip is about ½ in. long. C. H. Cu.

**THROMBOSIS** [thrɒmbo′sis], the formation within a vessel of a thrombus, or blood clot. A thrombus may form in a vein or an artery, the former being the most usual location. The veins of the legs and anus are the most common locations. Other vessels frequently involved are the veins of the small intestine and the veins of the pelvis; less frequently, the portal vein and the main artery of the leg. When a thrombus forms in any artery of the heart, the resulting condition is coronary thrombosis.

Thrombosis frequently follows an operation, but occasionally occurs in nonoperated cases. An infection causes the blood to clot and to fill the vessel. Injection treatment for varicose veins produces a thrombosis, but by a chemical process. Thrombi, which form in arteries, occur on calcareous deposits in these vessels and are to be attributed to stasis, or stoppage of the blood flow.

The symptoms of thrombosis in the veins are pain, tenderness, swelling, and an elevated temperature. If the thrombi are located in the leg, the veins are palpable and tender. A thrombosis in the artery of the leg causes severe pain and the leg becomes blue and cold. When a blood clot breaks loose, it becomes lodged in other parts of the body and is known as an embolus. Treatment includes rest in bed, elevation of the leg, and chemotherapy. Many surgeons advise opening of the vein and removal of the clot. Clots in the artery should always be removed. W. H. B.

**THROOP,** a borough in Lackawanna Co., in northeastern Pennsylvania, situated northeast of and adjoining the city of Scranton. It is located in the anthracite fields, and coal mining is its chief activity. Throop was incorporated in 1894. The borough is governed by a mayor and council. A mine disaster in April 1911 took a toll of 72 lives. It is served by the New York, Ontario and Western Railway. Besides coal mines the principal industrial establishments are a silk mill and several garment factories. Pop. 1950, 5,861.

**THROUGH THE LOOKING GLASS,** a children's story, by Charles Lutwidge Dodgson (Lewis Carroll), published in 1872. Like its predecessor, *Alice's Adventures in Wonderland* (1865) this tale was originally devised to entertain the young daughter of Henry George Liddell, also named Alice. The Alice of the story, who climbs through a looking glass, finds a world where everyday actuality is bewilderingly reversed. The plot of the tale is her dream quest for her heart's desire, a search symbolized by the moves of a gigantic chess game culminating in her being crowned as queen. Freudians interpret the books as mirroring the contradictions and frustrations of its author. It has also been considered a satire upon contemporary society, Alice representing the sane observer of an irrational world. Some thought it a satire on logic itself. Another opinion emphasizes the element of humorous self-portrayal, in which Carroll himself figures chiefly as the pleasantly inept White Knight. The variousness of these interpretations indicates the rich power of suggestion and the subtle undercurrent of meaning with which this children's nonsense volume is endowed, even though the author never lapses into didacticism. Other beloved characters of the story are Tweedledum and Tweedledee, and "Jabberwocky" is probably the best known nonsense rhyme in the language.

R. H. Fo.

**THRUSH,** the name given to many species of small to medium-sized songbirds united in the subfamily Turdinae of the family Turdidae or insect eaters. Among them are such distinct types as the Asiatic forktails, the nightingales, the stonechats, and the Old World redstarts. The American representatives of this group range in size from the robin (10 in.) to the bluebird (7 in.). They are found in virtually all parts of the world, including the larger oceanic islands. Thrushes have few characteristics that serve to separate them from their near relatives, the warblers and the Old World flycatchers; yet to a trained eye most of them are immediately recognizable, if only by their shape and carriage. They usually have relatively long, slender bills and legs; their plumage may be pied, all black, mainly brown or gray, or almost any combination of bright colors. Their habitats are equally diverse: in all countries one species or another is likely to occur in every sort of terrain available. Thrushes feed chiefly on insects, but many take fruits and

HAL H. HARRISON

*A wood thrush and its young*

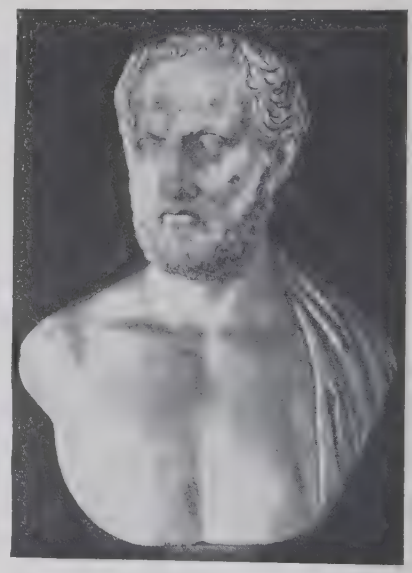
berries in season. As a group they are notable for their melodious voices, and some of them produce what is conceded by connoisseurs to be the sweetest bird music. Worthy of special mention in this respect are the shamas of the Asiatic tropics, the solitaires of the New World, the Eurasian nightingales, and the North American hermit thrushes.

H. G. De.

**THRYALLIS** [thraiæ′lɪs], any one of a group of small and rather woody shrubs, 1 to 2 ft. tall, cultivated in the southern United States and south to Brazil. They have yellow or reddish panicles of flowers. J. C. Wis.

**THUCYDIDES** [thyusɪ′dədiz] (c. 460-c. 399 B.C.), Athenian historian of the Peloponnesian War, was the son of Olorus, an Athenian citizen of the deme Halimus. The name Olorus had once been borne by a Thracian king whose daughter Hegesipyle had married the famous Athenian general Miltiades, and Thucydides may have been related to this family. This possibility is also indicated by the ancient tradition that the historian's tomb was located among the monuments of Cimon, the son of Miltiades, outside the Miletene gate on the way to the Piraeus. During his youth Thucydides knew the most glorious days of Athens, when the city achieved political and cultural supremacy under the leadership of Pericles. His admiration for this Athenian statesman is apparent throughout his *History of the Peloponnesian War* and especially in the famous funeral oration which he describes as having been given by Pericles, and is remarkable if one grants Thucydides blood ties with the family of Cimon, Pericles' bitter political foes.

Thucydides must have received the well-rounded education of the Athenian citizen of his day, not only in politics but also in literature and philosophy. It is doubtful, however, that he would have engaged in historical research had it not been for the Peloponnesian War. Although he probably did not write his account of this war until after 404, he began taking notes as early as 432 at the outbreak of hostilities between Athens and Sparta, and he was quick to realize the significance of this conflict. Thucydides is normally reticent about himself in the *History,* but he does relate that he was a victim of that plague (now identified as a virulent form of typhus) which devastated Athens in the early years of the war. His own military activities he relates in several chapters devoted to the Thracian campaign of 424 B.C. He was elected as one of the ten generals for that year and assigned to the Thracian area, where he probably had family connections through which he held mining property. In this campaign Thucydides was sent to relieve Amphipolis, then being besieged by the Spartans under Brasidas. He failed to raise the siege through no fault of his own, inasmuch as his force of only seven ships was scarcely adequate; but his lack of success was not taken lightly in Athens, and he was at once sent into exile. This separation from Athens for the next twenty years was not entirely unfortunate, however, for Thucydides was thus enabled to see the war from both sides. It can be deduced from his *History* that Thucydides returned to Athens and survived the war, but he did not live to finish the work he had projected. He described, in fact, only twenty-one of the twenty-seven years of the conflict. Nevertheless, although Thucydides slighted the intellectual and aesthetic heritage of the past in his interest in the development of power, his work is outstanding as the first genuine political history. It is characterized by a dispassionate, though somewhat cynical, point of view; for Thucydides' historical philosophy held that human nature is uniform and that man can foresee the future from a study of the past. A. E. R.



*THUCYDIDES*

COURTESY OF THE NEW YORK PUBLIC LIBRARY

**THUG,** a hoodlum or murderer, originally a member of a community of professional assassins who flourished in northern India during the later Mogul period and were suppressed by the British in the second quarter of the nineteenth century. The Thugs did not constitute a single caste, but were drawn from several different castes. They lived in towns and villages and followed other occupations when not engaged in their practice of thuggee, or murder and robbery. The Thugs traveled in bands of from ten to fifty when they set out on a murderous robbing expedition. Always unarmed, gentle, and courteous in demeanor, they attached themselves to individuals or small parties of travelers, and sometimes traveled for days with their prospective victims, awaiting a convenient opportunity to strike. Three Thugs were usually assigned to one victim. When the signal was given, two grasped his arms and legs, the third strangled him with a running noose. The body was buried with dispatch and the booty collected. No adult in a party was ever allowed to survive, but children were sometimes spared and adopted into the group. An apprentice was taken on a number of expeditions before he was allowed to do the actual strangling. The Thugs considered their

victims as sacrifices to the Hindu goddess Kali, and after each murder the band participated in a sacrificial feast of raw sugar. It was forbidden to murder holy men, outcasts, and women. This last tabu was not strictly observed, and in the nineteenth century many Thugs attributed their capture by the British to the breaking of this tabu, refusing to believe that their murders in general might be a crime. E. E. B.

**THULE** [thyu'li], a land known to the ancients as the northernmost part of the inhabited world. It was given its name by the explorer Pytheas of Massilia about 300 B.C. and was situated somewhere in the sea beyond northwestern Europe. Pytheas is supposed to have reached it after sailing six days from Britain; hence it has been variously conjectured to be one of the Shetland or Orkney Islands, the coast of Norway, or Iceland. The Romans sometimes referred to the land as "ultima Thule" (farthest Thule), and it thus became symbolic of any faraway, mysterious region. Pytheas reported that although the land was inhabited, it was bleak and its vegetation was sparse.

Thule is also the name of a small trading post established by the Danes on the northwest coast of Greenland in 1910, and the name is used by anthropologists to describe a form of Eskimo culture. G. Q.

**THULIUM.** *See* RARE EARTHS.

**THUMB, ALBERT** [tu'mb] (1865-1915), German linguist, was born at Freiburg in Breisgau on May 18, 1865. He taught from 1891 in Freiburg, later in Marburg, and from 1909 onward in Strassburg (Strasbourg). He died in Strassburg on Aug. 14, 1915.

Albert Thumb was perhaps the greatest of all specialists in Hellenistic, Medieval, and Modern Greek linguistic studies, and his works in these fields are still fundamental. He traveled in Greece and studied the Greek dialects, especially those of Amorgòs and Aegina, in their own areas. His masterpiece is *Die griechische Sprache im Zeitalter des Hellenismus, Beiträge zur Geschichte und Beurteilung der* Κοινή (1901). His *Handbuch der griechischen Dialekte* (1909, revised and enlarged by E. Kieckers in 1932) is highly condensed, but clear, useful, and very modern in its outlook, being based mainly on the application of geographical principles to linguistics. Other important works by Thumb include *Handbuch der neugriechischen Volkssprache* (1895), *Handbuch des Sanskrit* (1905), and *Grammatik der neugriechischen Volkssprache* (1915). He also wrote excellent linguistic works of a popular character and edited the fourth edition (1913) of K. Brugmann's *Griechische Grammatik.* G. B.

**THUN** [tu'n], a town in central Switzerland, in the canton of Bern, located on the Aare River 1 mi. below its efflence from the Lake of Thun and 16 mi. southeast of Bern, at an altitude of 1,854 ft. The town was founded in the twelfth century. In 1323 the castle and the town were sold to Bern. The older part of the town lies on the eastern bank of the Aare and centers around the twelfth-century castle of Zähringen-Kiburg which contains a historical museum with collections of old weapons and tapestries. The Rathaus built in 1589 was rebuilt in 1685. Near Thun lies the Alpine resort of Goldiwil, at an altitude of 3,280 ft. Many tourists use Thun as a gateway to the Alps, coming by train from Bern and continuing by boat from Thun to Interlaken. The climate of the town is between a mild Mediterranean climate and a bracing eastern inland climate. The July mean temperature is 64.5° F. A railroad center, Thun is noted for its art pottery and silver filigree. Other industrial products are cheese and metals. Pop. 1953, 25,200.

**THUN, LAKE OF** [tu'n], a lake of central Switzerland formed by a widening of the Aare River. Located southeast of Bern, it lies on the north side of the Bernese Alps at an elevation of 1,840 ft. The lake, 11½ mi. long and 2 mi. wide, has an area of 18 sq. mi. Its maximum depth is 702 ft. Along its shores are numerous resorts, such as Spiez, on the south shore (and on the railroad to the Lötschberg Tunnel), and Gunten, nearly opposite on the north bank. The north-shore towns face the high mountains of the Bernese Alps, a view for which the Lake of Thun is most celebrated. Lake steamers connect the town of Thun with Interlaken, which lies between the Lake of Thun to the west and the Lake of Brienz to the east. S. Van V.

**THUNDERSTORM.** *See* METEOROLOGY.

**THURBER, JAMES GROVER** (1894- ), American artist and author, was born in Columbus, Ohio, Dec. 8, 1894. He attended Ohio State University from 1913 to 1918. Tall, thin, and blind in one eye from a childhood accident, he suffered through the athletic and military program of the university in the World War I period. He once said that he fell down a good deal "because of a trick he had of walking into himself." He has drawn upon his life in Columbus for some of his best-known pieces.

Though barred from military service, Thurber had a phenomenal memory for names and details which made him valuable to the State Department as a code clerk in Washington and Paris (1918-1920). Afterward he returned to Columbus to write for the *Dispatch;* his special Sunday feature was a portent of things to come. In 1924 he joined the growing colony of Americans in Paris, working for the *Chicago Tribune* and developing his writing. Success was slow. He returned to New York and a job on the *Evening Post,* and began writing sketches which won him a place on the *New Yorker* in 1926. Thurber developed along with the magazine, but remained unique in his wry, allusive, psychoanalytical humor. His essays and drawings became books. With E. B. White, an early colleague on the magazine, he wrote a timely satire, *Is Sex Necessary?* (1929). It was followed in rapid succession by a series of books, each of which added to his growing fame: *The Owl in the Attic* (1931), *The Seal in the Bedroom* (1932), *My Life and Hard Times* (1933), *The Middle-aged Man on the Flying Trapeze* (1935), *Let Your Mind Alone* (1937), *The Last Flower* (1939), *Fables for Our Time* and *Famous Poems Illustrated* (1940), *The Male Animal* (with Elliott Nugent; 1940), *My World—And Welcome to It* (1942), *Many Moons* (1943), *Thurber's Men, Women and Dogs* (1943), *The Great Quillow* (1944), *The White Deer* (1945), and *The Thurber Carnival* (1945). H. Hr.

**THURGAU** [tu'rgau], a Swiss canton with an area of 388 sq. mi., southwest of Lake Constance, including most of the eastern part of the Swiss plateau, as well as most of the south shore of the lake. Thurgau is chiefly a rural section of crop fields and pastures, with a few large settlements. Frauenfeld is the capital and Romanshorn the chief lake port. Thurgau joined the Swiss Federation in 1803, after having been subject territory since 1460. Thurgau is bounded by Lake Constance and the Rhine River on the north, by Lake

Constance on the east, by the canton of St. Gallen on the south, and by the canton of Zürich on the west. Pop. 1953, 154,300. S. Van V.

**THURIBLE** [thyu′rıbəl] (Lat. *thuribulum,* censer), a container used by pagans, Jews, and Christians for burning incense. Anciently a vase with a perforated top, it was eventually equipped with four chains, one for raising the top, the others to enable the user to swing the thurible towards the person or object being incensed. In the West it is swung gently, one hand catching up the chains; in the East it is swung freely from the extremity of the chains. N. J. T.

**THÜRINGERWALD** or **THURINGIAN FOREST** [tü′rıŋərvɑ′lt, thyurı′njiən], a mountain system in Central Germany, extending from the neighborhood of Eisenach in the northwest to the Frankenwald in the southeast. The southern slopes reach down to the Werra River and the northern slopes descend toward the rivers Saale and Unstrut. The Saalfeld-Lichtenfels railway-line represents its eastern boundary. The Thüringerwald is about 70 mi. long by 6 to 22 mi. wide and averages 2,000 ft. in elevation, with peaks reaching to 3,240 ft. in the Beerberg and 3,022 in the Inselberg. Slopes of the block, descending steeply to the plains, are thoroughly dissected by deep stream valleys, the most beautiful of which is the Schwarza. The chain has a porphyritic backbone, with sandstone, granite, and porphyry predominating on the northwest and clay-slates in the southeast. The climate is mild and even. About 75 per cent of the area is forested, since poor soil and steep slopes render clearing unprofitable, although some meadow tracts exist. Most of the arable land is located in the valleys where the population engages in farming. Goat-raising and cattle-raising are carried on extensively, although the rather dense population has to rely primarily upon its highly developed industries, of which the most important are the toy industry and the manufacture of optical and precision instruments. With the exception of iron ore, lignite, and slate, the natural resources of the region are almost exhausted. C. C. H.

**THURINGIA (THÜRINGEN)** [thyurı′njiə, tü′rıŋən], a former state (*Land*), 6,020.82 sq. mi. in area, situated in central Germany and bounded by the *Länder* of Saxony-Anhalt on the north, Saxony on the east, Bavaria on the south, and Hesse on the west. It included the Thüringerwald, the northern part of the Rhön mountains, and the Saale River Valley. In the fifth century the Thuringians formed a large tribal state, which became tributary to the Huns and, conquered later by the Franks, was under Frankish rule from 634 to 804, when Charlemagne created the Thuringian Mark. In 1247, following the death of the Landgrave Henry Raspe, a war of succession broke out, which ended in 1263, when Henry of Meissen, of the house of Wettin, was awarded Thuringia. In 1485 it passed to Ernest, Elector of Saxony, and his descendants, by whom it was eventually divided into four duchies of Saxe-Altenburg, Saxe-Coburg-Gotha, Saxe-Meiningen, and Saxe-Weimar-Eisenach, and the principalities of Reuss and Schwarzburg. Under the Weimar Republic (1919-1933) the Saxe states were combined (with such modifications as the transfer of Coburg to Bavaria and the addition of several minor principalities) to form the *Land* of Thuringia. After World War II this state, which had a 1946 population of 2,927,497, was included in the Soviet occupation zone and, with other *Länder* of that zone, was dissolved in 1952.

About half of Thuringia is mountain forest and pasture land, and the rest is arable. The principal towns are Weimar (the former capital), Jena (a university and manufacturing town), Gera, Eisenach, Meiningen, and Gotha. Spas and health resorts include Friedrichroda, Ilmenau, and Oberhof. The Wartburg, the historic castle in which Martin Luther took refuge in 1521, is in the Thüringerwald south of Eisenach. The manufactured products of the area include optical glass, textiles, paper, leather goods, chemicals, scientific instruments, porcelain, musical instruments, Christmas-tree ornaments, and machinery. R. H. L.

**THURINGIANS,** a medieval tribe in Germany, very likely the descendants of the Hermunduri, a branch of the Suevi. The Thuringians first appeared in the fifth century A.D. as the allies of Attila. For a few decades in the latter part of the century, they controlled an area between the Elbe and the Rhine stretching southward from Saxony to the Danube. One of their kings married the niece of Theodoric, but this connection with the powerful Goths did not protect the kingdom from conquest by the Franks and Saxons about A.D. 531. T. B. J.

**THURNEYSEN, RUDOLF** [tu′rnaizən] (1857-1940), Swiss linguist and philologist, was born at Basel on Mar. 14, 1857. He studied Classical and Indo-European linguistics at Leipzig and taught at Jena, Freiburg in Breisgau, and Bonn.

Thurneysen began his career as a Latinist and continued throughout his life as a collaborator on the great *Thesaurus linguae latinae;* but he acquired his greatest renown in the field of Celtic studies, in which he soon became the leading figure. His *Handbuch des Altirischen* (1909) is far the best book on its subject and was translated into English and recast by Bergin in 1948. He also worked successfully on the Irish legends (*Die irische Helden- und Königssage bis zum XVII Jahrhundert,* 1921) and on Irish law (*Das keltische Recht,* in the miscellany *Studies in Early Irish Law,* 1936). He also published many articles, mainly of a linguistic character, in learned journals, and a number of works on Lycian, Lydian, and other ancient languages. Thurneysen died in Bonn, on Aug. 9, 1940. G. B.

**THURSDAY,** the fifth day of the week. It derives its name from the Middle English Thoresday, or Thursdaye, and it corresponds to the Roman *dies jovis.* Thor, the god of strength and thunder, defender and help in war, is the counterpart of Jupiter or Jove. The German counterpart to Thor is Donar, and the day is *Donnerstag.* Among Christians the Thursday preceding Easter is known as Holy Thursday, Big Thursday, Glory Thursday, Great Thursday, Green Thursday, Passion Thursday, and Maundy Thursday, and in general it commemorates Christ's washing the feet of his disciples. *See also* MAUNDY THURSDAY. A. L. H.-Q.

**THURSDAY ISLAND,** a low coral island in Torres Strait about 30 mi. off the northwest tip of Cape York Peninsula, Queensland, Australia. Its area is about 900 acres. The climate is hot and moist at all seasons due to the proximity of warm, tropical seas and the low latitude and altitude. There is a good harbor at Port Kennedy. The island prior to World War II was the base of operations for a fleet of small fishing boats that worked the reefs and shallow waters of Torres Strait, between Australia and New Guinea. Pearl shell, sea turtles, and *bêches-de-mer* or sea slugs made up most of the catch. The population, about 1,200 in 1935, was temporarily evacuated during World War II. The island belongs to Queensland. R. G. B.

**THURSTAN** or **TURSTIN** [thɜ′rstən, tɜ′rstɪn] (d. 1140), Archbishop of York, the son of Anger, or Auger, prebendary of St. Paul's, London, and the brother of Audoen, bishop of Evreux, was a native of Bayeux, Normandy, and a prebendary of St. Paul's. Thurstan was a clerk in the household of William Rufus, and became secretary to Henry I, who secured his election as archbishop of York in 1114. But Ralph d'Escures, Archbishop of Canterbury, refused to consecrate Thurstan unless he professed obedience to the see of Canterbury. Their dispute continued until 1119, when Thurstan was consecrated at Reims by Pope Calixtus II and as a consequence was forbidden by Henry to set foot in England. Three years later, however, he returned to England and was reinvested with the archbishopric, as a result of having rendered Henry useful services in Normandy. In 1137 he prevailed on David I of Scotland, who was preparing to invade England, to agree to a truce, and the following year raised an army in Yorkshire which routed the Scots at the Battle of the Standard. Thurstan was the founder of a number of monasteries in the north of England, and early in 1140 he entered the Cluniac order at Pontefract, where he died on Feb. 6, 1140. C. W. D.

**THUTMOSE III** [thutmo′sə] (c. 1501-c. 1448 B.C.), Egyptian pharaoh of the Eighteenth Dynasty, a great military leader and capable administrator, considered by many to have been the ablest ruler of Egypt in antiquity. It is uncertain whether he was the son of Thutmose I or Thutmose II, but during the first eleven years of his reign, which began in 1491 B.C., he was little more than the consort of the great Queen Hatshepsut. The death of the queen (c. 1480 B.C.) was the signal for the revolt of tribes in southern Syria which were restless under Egyptian domination. These tribes were supported in their uprising by the king of Kadesh, whose territory lay farther north along the Orontes River. In 1479 B.C. Thutmose took the field against the Syrian rebels, defeated them at Armageddon (Megiddo), and re-established Egyptian control in southern Syria. In the succeeding years more than fifteen Syrian campaigns were undertaken, carrying Egyptian arms far to the north. The seizure of Phoenician cities gave Thutmose a base for operations against the king of Kadesh, and after Kadesh fell Thutmose moved eastward across the Euphrates, where he defeated the powerful Mitannians. Thus, in the reign of Thutmose, there was created an Egyptian empire which extended from the third cataract of the Nile in the south to the borders of Anatolia in the north; the eastern Mediterranean was an Egyptian lake, and the navy of Thutmose may even have entered the Aegean. In keeping with his wealth and power, Thutmose was active in repairing and building temples in Egypt, particularly at Karnak. The twin obelisks which he erected in the precinct of Ra at Heliopolis now stand on opposite sides of the Atlantic Ocean: one on the Thames Embankment in London, and the other in Central Park, New York City. T. B. J.

**THYESTES.** *See* ATREUS, HOUSE OF.

**THYME** [tai′m], common name given to *Thymus,* a genus of small shrubs in the mint family. These erect or creeping perennials have small flowers and entire leaves borne in loose terminal or axillary clusters, and give off a pungent, mintlike odor. They are most numerous in the Mediterranean region, although the 50 species comprising this genus are natives of temperate climates. They are the source of valuable medicinal oils, are used as seasoning, and are also grown for garden ornamentals. The species most often planted in rock gardens and used for edging borders is the wild or creeping thyme, *T. serpyllum.* It has oblong, short-stalked leaves, prostrate stems, and many branches; although a native of the Old World, it is widely naturalized in the United States. The chief source of thymol, a substance much used in medicine is the common thyme, *T. vulgaris.* This plant

THOMÉ—DR. LASCOFF

*The root, leaf, and flower of the thyme plant*

is native to southern Europe and is cultivated extensively there. The narrow, sessile leaves and dense clusters of purple flowers are borne on slender, whitish branches; the whole plant grows to a height of about 8 in. The leaves are used in seasoning, either green or dried. M. G. W.

**THYMUS** [thai′məs], a ductless organ, found in all vertebrates. In man, it is situated in the lower part of the neck and the superior mediastinum.

**Structure.** The thymus is of grayish-red color and consists of two adjoining longitudinal lobes, joined, but rarely fused together. The lobes are subdivided into many lobules, made up of cortex and medulla, and is innervated by branches of both the vagus and the sympathetic nerves. The size of the thymus varies considerably with age. It increases up to the time of puberty and then begins to undergo continuous involution. In the embryo, the thymus is epithelial in origin, but prior to birth it becomes lymphoid, and this lymphoid character of the gland increases with age. Embryologically, it is associated with the parathyroid glands.

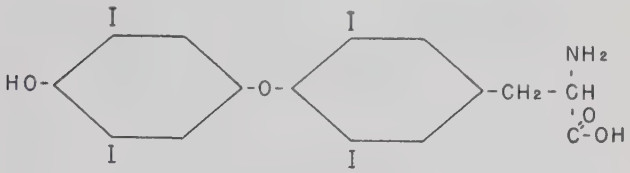
**Function.** The function of the thymus is still unknown. Probably, no organ is subject to so many contradictory hypotheses. Some authorities regard it as an endocrine gland, others as part of the lymphatic system, and still others as merely vestigial structure. The thymus is found in all vertebrates and its congenital absence is rare, but its presence, apparently, is not essential to life. Some authorities, however, attribute to the thymus an important part in growth, bone formation, and blood production. Doubts as to the endocrine nature of the thymus are contradicted by its interrelationship with the other glands of internal secretion, and since involution of the thymus usually begins at puberty it is possible that the gland is affected by the development of the reproductive organs.

*Disorders of the Thymus.* The thymus is subject to infection, inflammation, syphilis, and tuberculosis and is occasionally the site of tumors, chiefly malignant. Malnutrition and certain acute infections cause it to shrink and atrophy. On the other hand, it becomes considerably enlarged in Graves' disease, Addison's disease, acromegaly, rickets, and in about 20 per cent of cases of myasthenia gravis. The thymus becomes enlarged and fails to undergo involution in still another condition, known as status thymicolymphaticus. This condition is associated with hyperplasia of lymphatic tissues, a fat, flabby, overgrown body, adrenal atrophy, and underdeveloped heart and blood vessels. Victims are subject to attacks of cyanosis, coma, convulsions, and sudden death, known as *mors thymica.* Both the physiology and pathology of the thymus remain largely unsolved. *See also* ENDOCRINOLOGY.

B. Van R.

**THYRATRON.** *See* ELECTRONIC CIRCUITS (*Electronic Control*).

**THYROID GLAND** [thai′rɔid], a bilobed structure in the neck of mammals beneath the larynx. It arises as an outgrowth from the floor of the embryonic pharynx and consists of a series of small spheres of cells called



*THYROXINE*

follicles. The cavity of the follicle is normally filled with a storage form of thyroid secretion called thyroglobulin, an iodine-containing protein. Enlargements of the thyroid gland may be associated with either hypo- or hyperfunction and are called goiters. In 1916, Dr. E. C. Kendall, of Rochester, Minn., crystallized the iodine-containing hormone, thyroxine, for the first time. In 1926, Harrington, working in England, established the chemical nature of thyroxine and indicated that it was a derivative of the amino acid, tyrosine.

Traces of iodine are required in the diet for the production of thyroxine, and a high incidence of goiter is found in geographical regions where the iodine content of food is low. A new phase of thyroid study began in the 1940's with the discovery by the MacKenzies, of Baltimore, and Astwood, of Boston, that a series of drugs, of which thiourea and thiouracil are the most used, could block the production of thyroxine by the thyroid. Such drugs are frequently used in lieu of surgery to treat hyperthyroidism.

The function of the thyroid hormone is to stimulate oxidative processes in the body, i.e., the basal metabolic rate. When the hormone is absent, all metabolic activities are retarded; when it is present in excess, they are accelerated. *See also* GOITER.

R. G.

**THYRSIS** [thɜ′rsɪs], a poem published in 1866 by Matthew Arnold, commemorating his friend Arthur Hugh Clough who died in Italy in 1861. It is a pastoral elegy, Clough and Arnold figuring as the shepherds Thyrsis and Corydon. The spirit that Arnold recognized in Clough and in the Oxford countryside is presented as an indication of the persistent attractiveness of the idea of truth and of the desirability of striving toward it.

W. D. T.

**TIANG** [tyæ′ŋ], a medium-sized antelope, *Damaliscus korrigum,* of the upper Nile region of Africa. It is very similar to the topi of East Africa. A relative of the hartebeests, it has high shoulders and a long, slender head. The general color is cinnamon, except for the face, the front of the legs, and the bushy tail-tip, all of which are black. Both males and females have ringed horns about 20 in. long. *See also* ANTELOPE; HARTEBEEST.

V. H. C.

**TIARA** [tiɑ′ra; tɑiɛ′ərə] (Latin, from Greek *τιάρα,* an ancient Persian headdress), in ecclesiastical usage the pope's triple crown, a tall headpiece, somewhat ovate in shape, topped by a small cross, encircled by three diadems, and having two pendants attached at the back. The tiara is an insigne of sovereignty; at liturgical functions the pope wears the episcopal miter.

In the development of the tiara three periods may be distinguished. (1) The *camelaucum* was worn from the seventh or eighth century, probably first by the popes of Greek or Syrian origin. (2) Certainly before the twelfth century a royal circlet was added, which became a spiked crown by the end of the thirteenth century. (3) A second circlet was added by Boniface VIII (d. 1303), possibly as symbolic of his views concerning the twofold (spiritual and temporal) power of the papacy. Mention of three crowns is made in 1316, but the earliest monumental representation is found in an effigy of Benedict XII (d. 1342). Why a third crown was added is not known, though interpretations of the alternative name "triregnum" (Latin, triple rule) have been invented, e.g., authority over heaven, earth, and hell.

N. J. T.

**TIBBETT, LAWRENCE MERVIL** [tɪ′bət] (1896– ), American baritone, was born in Bakersfield, Calif., Nov. 16, 1896. From acting in Southern California stock companies he advanced to light opera and thence, after studying voice in New York with Frank La Forge, to the Metropolitan Opera Company, where he made his debut in 1923. After singing secondary roles for two seasons, he began a series of triumphs in important roles, including those in such American operas as Deems Taylor's *The King's Henchmen* (1927) and *Peter Ibbetson* (1931), Louis Gruenberg's *The Emperor Jones* (1933), and Howard Hanson's *Merry Mount* (1935). He has sung in recital tours throughout America and Europe, in radio, and in motion pictures.

W. Li.

**TIBER** or **TEVERE** [tai′bər, te′vere], second longest river in Italy, draining Latium, Umbria, and parts of Tuscany, and flowing into the Tyrrhenian Sea 20 mi. southwest of Rome. Its total length is 247 mi., and it drains an area of 6,700 sq. mi. The principal tributaries of the Tiber are the Topino, the Nera (with the Velino), and the Aniene (the ancient Anio) from the east, and the Nestore, the Chiana, and the Nepi from the west. The sources of the Tiber are in the Apennines on the border between Tuscany and Romagna, north of San Sepolcro. Its course is meandering, passing Città di Castello, Perugia, Todi, and Rome, and it enters the sea through two branches, the Fiumara near Ostia, which is the natural mouth, and to its right the artificial Fiumicino canal.

A safe anchorage at the mouth of the river was not afforded until the harbor of Ostia was built in the fourth century B.C. Later the Emperor Claudius built a new harbor on the northern side of the delta, which Trajan connected with the main branch of the river by a channel. Claudius, in an effort to stem the disastrous periodical floods of the Tiber, also built two large ditches near the mouth of the

river, one of which was enlarged by Trajan to form the Fiumicino canal. With the downfall of the Roman Empire, traffic on the Tiber declined and the port of Ostia filled with sand. At the end of the seventeenth century the river harbors of Ripagrande and Ripetta were built. In the nineteenth century, after an extremely severe flood, the government constructed walls along that part of the Tiber which flows through Rome. Other works, completed in 1948, include straightening the course of the river below Rome, installing new sewers, and reinforcing the earthen banks from Rome to the mouth of the river. At the present time, the Tiber is navigable by small craft during certain seasons to the confluence of the Nera, 40 mi. north of Rome, and a modern harbor is in operation on the southern outskirts of Rome. The Tiber and its tributaries, notably the Nera and the Aniene, are utilized for the production of hydroelectric power. Especially important is the group of hydroelectric plants at the foot of the Marmore waterfalls near Terni.

R. G. W.

**TIBERIAS** [taibi'əriəs], (*Heb.* Tveriah), a city in Israel, situated in a depression about 700 ft. below sea level on the western shore of the Sea of Galilee, also known as Lake Tiberias. Named after the Roman emperor Tiberius, the city was one of the Four Holy Cities of Palestine and an important center of Jewish learning from the Talmudic period to the Crusades. After a period of decline it regained its position briefly during the second half of the sixteenth century, but it was not until after 1948 that an accelerated development in its economic life made Tiberias one of the most flourishing centers in Galilee. In 1954 the population increased from 5,000 to 17,000, largely drawn by the mild climate and the thermal baths which have made the city famous since ancient times. New industries have been established, including machine shops, sausage, candy, and box factories; fisheries are operated on the Sea of Galilee.

Z. Y. H.

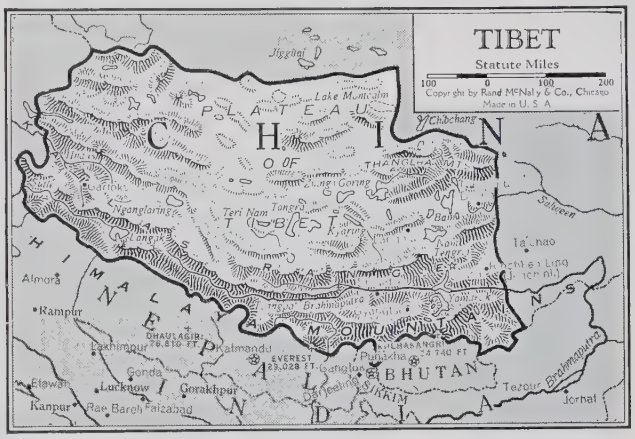
**TIBERIUS (TIBERIUS CLAUDIUS NERO CAESAR)** [taibi'əriəs] (42 B.C.-A.D. 37), Roman emperor, was born in Rome, Nov. 16, 42 B.C. Tiberius was the son of Livia Drusilla and Tiberius Claudius and the stepson of Augustus. After the death of Agrippa in 12 B.C., Tiberius and his brother Drusus became the principal generals of Augustus. When Drusus died in 9 B.C., Tiberius became the principal support of the aging emperor. He was subsequently adopted by Augustus and received the imperium and tribunitian power. Following the death of Augustus in A.D. 14, Tiberius was confirmed as emperor by the Senate and began a reign remarkable for its contradictions. On the one hand, he had many constructive laws passed, took care that his governors did not impose excessive taxation on the provinces, and lightened the financial burden of Rome itself by practicing a rigid economy. On the other hand, the historian Tacitus described him as a man of ruthless tyranny and cruelty. After the death of the two young men who might possibly have been his heirs—his nephew Germanicus (died A.D. 19) and his son Drusus (died A.D. 23)—Tiberius relied heavily upon the praetorian prefect, Sejanus, who was largely responsible for affairs in Rome when Tiberius withdrew to Campania, and later to Capri. Sejanus engaged in treasonable activities and in A.D. 31 he was executed at Tiberius' command. Tiberius died at Misenum, Mar. 31, A.D. 37, and was succeeded by his grandnephew, Gaius (Caligula).

T. B. J.

**TIBET,** a region of central Asia, which during most of its history has been a self-governing part of China. Under the Sino-Tibetan treaty signed at Peking on May 23, 1951, Tibet became virtually a province of Communist China. In 1928, the two new Chinese provinces of Tsinghai and Sikang had been set up, including both Chinese territory and what is usually termed "Nearer Tibet." "Farther Tibet," or Tibet proper, is approximately 350,000 sq. mi. in size. Tibet is bounded by the Chinese provinces of Sinkiang on the north, Tsinghai on the northeast, and Sikang on the east, by Bhutan, Nepal, and India on the south, and on the west by India and Kashmir.

## GEOGRAPHICAL FEATURES

**Topography.** Tibet consists of a high plateau with an average altitude of about 16,000 ft.; the valleys are no lower than 12,000 ft., and mountain ranges and snow-capped peaks, the highest in the world, extend above 28,000 ft. The country



may be divided into three major physiographic regions: Chang Tang, Southern Tibet, and Eastern Tibet.

Chang Tang, the northernmost region, lies just south of the Kunlun Mountains, which form its northern border. This chain has fairly continuous peaks which rise to heights of more than 23,000 ft.
